commodities or foreign exchange, if in the interval before repayment the money value of the things bought has risen by an amount many times the charge for interest. The currency units in which the loan is repaid are worth much less than those in which it was originally received. If temporary borrowing is stimulated, that means that the banks create more credit and the unspent margin is further increased, and all the effects of inflation are accentuated. Moreover discredit of the currency makes long-term borrowing impossible. People will not put their savings in investments which depend for their value upon a depreciating unit. The Government, having started inflationary borrowing, finds that it cannot borrow in any other way. A vicious circle of inflation is set up, and it is only too likely to end in a complete breakdown of the currency system, the value of the unit in gold or in wealth dwindling to an infinitesimal fraction of its former parity.

Devaluation and Deflation.—When discredit has brought depreciation of the unit beyond a certain point, a restoration of the former gold value becomes impossible. The gold standard can only be restored by devaluation, the adoption of a new parity, not differing by much from the existing gold value of the currency in the market. Devaluation was common in the middle ages, when the imperfection or debasement of the coin had led to a depreciation of the unit, and a restoration was deemed impracticable or undesirable. Nowadays it is sometimes denounced as being something like a fraud, which robs creditors of their due. This is a misapprehension of the real nature of a monetary standard. The equivalence of the monetary unit to a specified weight of gold or silver is established by law and can be altered by law. Creditors have no vested right in the maintenance of the law unchanged. On the other hand when the depreciation is not so great as to make a return to the old parity with gold impracticable, there are real advantages in re-establishing it. The old parity commands confidence in a way that no new parity could do.

The process by which a currency is raised in value, either to its former gold parity, or to a new parity above its existing value, is called deflation. Deflation requires a diminution of the consumers' income and the consumers' outlay, and is usually effected by means of a contraction of credit and similar measures. The shrinkage of demand and the fall of prices have a paralyzing effect on enterprise, causing trade depression, unemployment and bankruptcies. It is on account of these injurious consequences that the value of a currency unit can only be raised to a very limited extent. One of the features of the "trade cycle" (the periodic fluctuations of productive activity familiar to economists between 1815 and 1914) was a general worldwide rise of prices, followed by an equally general contraction of credit and fall of prices. The unemployment and trade depression characteristic of the latter phase of the cycle were symptoms of deflation, though the preceding inflation, applying as it did to all gold standard countries, was not based on inconvertible paper money. MONEY-LENDING. In primitive societies the taking of interest for the loan of goods or services rendered, in transactions between members of the same community, was unknown. All that was expected was the return of similar goods or services. With the substitution of money for corn and cattle, this idea that advantage must not be taken of the necessities of one's kindred still prevailed, and it was adopted in Europe by the Church. Thus in England it was unlawful at common law for a Christian to take interest on money lent, a prohibition enforced by various mediaeval enactments on usury (*q.v.*).

In 1897 a select committee of the House of Commons, after an exhaustive enquiry adopted the proposal originally made by the present writer that the equitable doctrine of unconscionable bargains with heirs and reversioners should be applied to all money-lending transactions. This proposal, with further provisions, was embodied in the Money-Lenders Act 1900. By this statute, although there is no restriction upon the rate of interest, where proceedings are taken by a money-lender for the recovery of money lent or the enforcement of any agreement or security, and there is evidence that the interest charged is excessive or that the amounts charged for expenses, enquiries, fines, bonus, premium, renewals or any other charges are excessive, and that in either case the transaction is harsh and unconscionable or is otherwise such that a court of equity would give relief, the court may re-open the transaction and take an account between the money-lender and the person sued, and may, notwithstanding any statement or settlement of account or any agreement purporting to close previous dealings and create a new obligation, re-open any account and relieve the borrower from payment of any sum in excess of the sum adjudged by the court to be fairly due, as the court, having regard to the risk and all the circumstances, may adjudge to be reasonable; and if any such excess has been paid or allowed in account by the debtor, may order the creditor to repay it, and may set aside or revise any security or agreement, and if the money-lender has parted with the security may order him to indemnify the borrower.

In proceedings under the Betting and Loans (Infants) Act 1892, where a money-lending circular is sent to an infant the sender shall be deemed to have known that the person to whom the document was sent was an infant, unless he can prove that he had reasonable grounds for believing such person to be of full age. A money-lender is defined as a person whose business is that of money-lending, or who advertises or announces himself or holds himself out in any way as carrying on that business, but does not include a pawnbroker, a friendly society, a body corporate empowered by special act of parliament to lend money, a banker or a body corporate exempted by order of the Board of Trade.

By the Money-Lenders Act 1927 ss. 2 and 3 of the Money-Lenders Act 1900 are repealed and the whole of the Money-Lenders Act 1911. Every money-lender must now take out annually, whether carrying on business alone or as a partner in a firm, an excise licence in respect of every address at which he carries on business. Such licence must show the money-lender's authorized name and authorized address or addresses. Such name and address means those under which a money-lender is authorized by a certificate to carry on the business of money-lending. The name must be his true name. The duty on an excise licence is £15. The certificate, which is only granted upon evidence of good character, capability and responsibility, may be granted by a petty sessional court. If refused there is an appeal to quarter sessions. The money-lender's name must be stated on all documents issued by him. Restrictions are also imposed on money-lending advertisements and the employment of touts is prohibited. No contract is enforceable unless a note or memorandum is signed by the borrower, and a copy thereof given to him. Such note must contain full particulars of the loan. Compound interest is prohibited, and the rate of interest may not be increased by reason of any default in payment. Upon request the money-lender must supply to the borrower information as to the state of the loan. Where the interest exceeds the rate of 48% the court, unless the contrary is proved, shall presume that the interest charged is excessive and the transaction harsh and unconscionable. A charge for expenses in negotiating a loan is made illegal. Proceedings for the recovery of money lent must be brought within 12 months from the date on which the cause of action accrued. The act applies to Scotland,

but not to Northern Ireland.

See H. H. L. Bellot, *Legal Principles and Practice of Bargains with Money-Lenders* (1906); G. Stone and D. Meston, *Law Relating to Money-Lenders* (1927). (H. H. L. B.)

United States.—In the United States each State may prescribe its own maximum rate of interest, although a few do not fix any. National banks conform to the legal interest rate of the State in which they are located, and if in a State where no legal rate is established they may not charge more than 7%. A charge of interest above the legal rate constitutes usury, for which offence various penalties are prescribed by the laws of different States. In Maryland, New York and New Jersey corporations, when borrowing money at rates in excess of the legal rate, are precluded from setting up the defence of usury, and hence are legally bound by any contract they may make to pay interest at any rate. The laws of the State of New York permit demand loans of $5,000 or more, for which stock or bonds or other negotiable instruments have been pledged as security, to be made at any interest rate. A time loan, however, with stock exchange collateral, at a rate higher than 6%, is usurious. In many States where a regular legal rate is fixed there is permitted a higher rate by special contract. Lenders often evade the legal rate of interest law by charging the borrower a "commission" in addition to the interest.

The legal rates of the various States and Alaska and some of the particular provisions are as follows:—

Alabama—8%; by contract 8%; lender forfeits interest as penalty for usury. *Alaska*—8%; by contract 12%. *Arizona*—6%; by contract 10%; penalty as in Alabama. *Arkansas*—6–10%; by contract 6–10%; lender forfeits principal and interest as penalty for usury. *California*—7%; by contract 12%. *Colorado*—8%; by contract 12%. *Connecticut*—6%; by contract 12%; penalty for usury of imprisonment or fine or both and no action may be brought for recovery of either principal or interest. *Delaware*—6%; by contract 6%; but parties may agree in writing on any rate where the loan exceeds $5,000 on accepted collateral security and is payable on demand. No penalty for usury, but action at law may be had for recovery of interest over 6%. *District of Columbia*—6%; by contract 8%; penalty as in Alabama. *Florida*—8%; by contract 10%; penalty as in Alabama. *Georgia*—7%; by contract 8%; penalty as in Alabama. *Idaho*—7%; by contract 10%; penalty as in Alabama. *Illinois*—5%; by contract 7%; penalty as in Alabama. *Indiana*—6%; by contract 8%; lender forfeits excess interest as penalty for usury. *Iowa*—6%; by contract 8%. *Kansas*—6%; by contract 10%. *Kentucky*—6%; by contract 6%. *Louisiana*—5%; by contract 8%. *Maine*—6%; by contract any rate. *Maryland*—6%; by contract 6%; but 3½% per month may be charged on petty loans of $300 or less made by specially licensed loan agencies. Corporations are precluded from setting up usury as a defence. *Massachusetts*—6%; by contract any rate. *Michigan*—5%; by contract 7%. *Minnesota*—6%; by contract 8%. *Mississippi*—6%; by contract 8%. *Missouri*—6%; by contract 8%. *Montana*—8%; by contract 10%. *Nebraska*—7%; by contract 10%. *Nevada*—7%; by contract 12%. *New Hampshire*—6%; by contract any rate; lender forfeits three times the excess interest as penalty for usury. *New Jersey*—6%; by contract 6%; lender forfeits all interest as penalty for usury. Corporations are precluded from setting up usury as a defence. *New Mexico*—6%; by contract 10% if there be collateral security for the loan, 12% if there be no collateral security. Lender forfeits double the interest as penalty for usury; usury is also a misdemeanour punishable by fine. *New York*—6%; by contract 6%; demand loans of $5,000 or more secured by negotiable collateral, any rate; corporations are precluded from setting up usury as a defence. Contract is void as to both principal and interest as penalty for usury; usury is also a misdemeanour. *North Carolina*—6%; by contract 9%; penalty as in Alabama. *North Dakota*—6%; by contract 10%; penalty as in Alabama. *Ohio*—6%; by contract 8%; penalty as in Indiana. *Oklahoma*—6%; by contract 10%; lender forfeits double the interest as penalty for usury. *Oregon*—6%; by contract 10%; lender forfeits both principal and interest as penalty for usury. *Pennsylvania*—6%; by contract 6%; special provisions for licensed money-lenders; penalty as in Indiana. *Rhode Island*—6%; by contract 30%. *South Carolina*—7%; by contract 8%. *South Dakota*—7%; by contract 12%. *Tennessee*—6%; by contract 10%. *Texas*—6%; by contract 10%. *Utah*—8%; by contract 12%. *Vermont*—6%. *Virginia*—6%; by contract 6%; bankers, brokers and moneyed corporations may loan money or discount at not exceeding ½ of 1% for 30 days, minimum fee 50 cents. Exceptions in favour of insurance companies loaning money on insurance policies. *Washington*—6%; by contract 12%. *West Virginia*—6%; by contract 6%. *Wisconsin*—6%; by contract 10%. *Wyoming*—7%; by contract 10%; lender forfeits interest as penalty for usury. (J. H. B.)

MONEY MARKET. This term is sometimes used to include the whole machinery of a financial centre and so to include the Stock Exchange and the instruments of company promotion. More usually, it is confined to the organization which provides credit of short duration, consisting of the banks which make advances for short periods, the discount houses which buy and sell bills of exchange, the accepting houses or merchant bankers which, with the banks, provide trade with first-class bills by putting their name to them for a small commission. Dealers in exchange who buy and sell foreign currencies and foreign bills of exchange, are also sometimes included, but in London the parlance of the City usually confines the term to the banks, the accepting houses and the discount houses.

At the centre of the system stands in London the Bank of England, and in other centres the central bank, which derives most of its power and prestige from acting as banker to the Government and to the other banks, receiving deposits from them and making advances to them, though in London, as will be explained, the Bank of England's advances to banks are seldom made directly. In America, owing to its vast area, there are twelve central banks known as Federal Reserve banks, co-ordinated under the regulation of a Federal Reserve board which sits at Washington. The Bank of England is peculiar as a central bank by reason of its freedom from Governmental control, though this freedom is more apparent than real. While in other countries it is usual for the Government, by a power of appointing part of the board of directors and sometimes by owning part of the capital, to have a direct influence on, or interest in, the operations of the central bank, the Bank of England is by its constitution, a joint-stock bank owned by shareholders who are members of the general public, with its board elected nominally by the shareholders, though in fact any vacancies are filled by the board itself subject to confirmation by the shareholders. But while the Bank of England is thus, in appearance, an ordinary company working to earn dividends for its shareholders, the prestige that it gains from acting as banker to the Government gives the latter, as its most important customer, power to exercise strong influence on its policy. In actual practice, the bank and the Treasury work together to regulate England's monetary policy, especially since the World War, which, by creating a huge public debt, both long-dated and floating, has made the Government a much more important factor than it was before in the monetary position. On the other hand, in other centres, especially in Europe, although Government influence over the central bank is more direct, the experiences of the war and of the after-war period have demonstrated the necessity for freeing the bank from it as far as possible, especially in the matter of confining the power of the Government to demand unlimited advances from the bank.

The need for this restriction arises from the fact that advances made by a central bank increase the amount of money, or purchasing power, in the hands of the community, whether the advances are made in the form of bank-notes issued for this purpose or in the form of a credit in the bank's books (as is done in England) against which the Government can draw cheques; the cheques are paid in to their banks by the contractors and others who receive them; and the advance made to the Government increases the amount of "cash in hand and at the Bank of England" held by the other banks, and so widens the foundations on which

they build their credit operations. The same increase in purchasing power is effected whenever a central bank makes an advance to any kind of borrower, and its power to widen the basis of credit, when moderately exercised, gives great elasticity to the monetary systems of those countries in which it has been highly developed. Those who charge the English banking system with cast-iron rigidity because the Bank of England's note issue has to be covered (above a certain fixed line) pound for pound with gold, forget that the bank's power to create credits in its books, by making advances or by buying securities, is regulated solely by the bank's own prudence. The ease with which a central bank can create new purchasing power, either by the printing press or by entries in its books, afforded, during and after the war an easy way of financing themselves to impecunious Governments which had not enough courage to tax their citizens or reduce expenditure; when purchasing power is increased without a corresponding increase in goods to be purchased, prices go up and inflation begins with disastrous consequences if carried too far. Hence the need for restricting the demands of Governments on central banks, to which is entrusted the duty of regulating the supply of money so as to maintain the country's gold stock and the exchange value of the currency, which is liable to immediate deterioration if inflation sets in. This duty of maintaining the gold stock has been always an especially important part of the Bank of England's functions, owing to London's exceptional position (now shared by New York) as a free gold market, and by performing this duty and acting as the banker of the Government and the other banks it has long ceased to be a company working for its shareholders (though it incidentally earns them a dividend) and become a national institution, working to give the country sound money.

Expansion and Contraction of Credit.—This it does by expanding and contracting the volume of credit and by varying its price. It expands credit by making advances and buying securities, so giving the power to those who borrow from it or sell to it to draw cheques which they can pay into their banks, or to take notes from it which they can put into circulation or turn into gold for purposes of export; it contracts credit by selling securities or by borrowing in the market from the discount houses and other large dealers in money and it regulates the price by raising or lowering its rate of discount, at which it buys bills of exchange, and its rate for advances, which is usually $\frac{1}{2}\%$ higher. By making changes in its official rate it affects the general price of credit throughout the country, because the other banks base on Bank rate the rates that they allow to depositors (subject to the bargaining power of the depositor) and the rates at which they make advances to their borrowing customers. The effect of a rise in bank rate thus makes credit dearer to all who are engaged in business and so tends to induce them to reduce their commitments by selling commodities that they are carrying on borrowed money; a lower level of prices is thus produced which stimulates exports and reduces imports and tends to turn the foreign exchanges in favour of London and to check demands on its gold stock, to protect which a rise in bank rate is usually designed. By these methods the central banks of the countries which have currencies based on gold, work to maintain the value of the national money as measured in those of other countries and so give to international trade the immeasurable blessing of comparatively stable rates of exchange, which is the chief justification of the gold standard, in spite of the obvious drawbacks to which its critics can point. It is true that gold, owing to the large fluctuations in its rate of output has failed, in the past, to provide the world with a stable measure of value; but the use of the gold standard by the chief commercial countries of the world knit all their currencies together by means of the gold link, made price movements in all of them more or less uniform, and prevented the wild fluctuations in exchange which made foreign trade a gamble during the after-war period, when the gold standard was for the time being abandoned. It may also be hoped that closer co-operation between central banks and a more conscious and general effort towards the stabilization of prices will produce greater stability in spite of fluctuations in the output of gold, until the time arrives when the world is sufficiently civilized to be able to adopt an international paper currency.

When credit has to be expanded, owing to seasonal demands such as occur regularly at the end of June and still more at the end of December, a large business is usually done by the Bank of England in discounts and advances, the other parties to the transaction being generally the discount houses. It is not usual in England for the banks to borrow directly from the central bank—they keep habitually a large amount of money lent, from day to day or for a week, to the discount houses and when they wish to reinforce their holding of cash, they call in part of these funds from the latter, who are thus obliged, if the process goes far enough, to borrow from the Bank of England, either by taking bills to it for discount, or by applying to it for advances. By this method, new credit is created by the Bank of England which is paid in by the discount houses to their banks and increases the latter's holding of "cash at the Bank of England."

The Provision of the Means of Payment.—On the basis of the credit provided, or the notes issued, by the central bank, the other banks in countries such as America and England, with a developed banking system, provide the community with the deposits which are potential money, because they confer on their owners the right to draw the cheques, by which the immense majority of commercial transactions are settled. The central bank issues notes and creates deposits with an eye on the relation between its gold and its liabilities in the form of notes and deposits outstanding. In America a proportion is fixed by law which has to be maintained by the bank subject to the possible payment of a tax. In England there is no law about the amount of deposits that the bank may have in relation to gold reserves, but all notes above a hard and fast line have to be backed by gold. There is much to be said in favour of both systems, and the one adopted in America is generally approved and adopted in other countries; but the difference between them is largely formal and is not nearly so important as the skill and prudence with which the system is handled by those in charge of it. The notes issued by the central bank except the American Federal reserve notes are "legal tender" —that is, have to be accepted by creditors in payment of debts. (In England Treasury notes are legal tender, but it may be hoped that by the time these words are published, this war-time excrescence on the British monetary system will have been abolished, and the Treasury notes fused with the Bank of England's note issue). The credits in the books of the central bank, and the cheques that can be drawn against them are not legal tender; but the credits are counted by the other banks as "cash" and give them the right to demand legal tender from the central bank.

On this foundation of legal tender money and credit at the central bank the other banks (the "commercial banks" as they are sometimes called) build a larger structure of credit by buying securities and making advances to their trade and general customers. Having only been gradually evolved into a central bank, the Bank of England still does a certain amount of business for private customers; but the American Federal Reserve banks, and other central banks set up in the light of modern experience, are usually confined to the task of working for the Government and for the other banks. When a central bank makes advances or buys securities it creates deposits for itself, because whichever of the commercial banks receives the credit so created will add it to its balance at the central bank; but when a commercial bank makes advances or buys securities it creates deposits possibly for itself, if the cheques drawn against the new credit that it makes are handed to its own customers who pay them in to their accounts with it, but more probably for one of its rivals who, however, are at the same time creating deposits for it.

Credit and Industry.—When a customer of bank A borrows from it £10,000, the immediate effect of the transaction is an addition of this sum to the customer's current account on the liabilities side of the balance-sheet and of the same amount to the "loans and advances" item on the assets side, and a consequent slight decline in the proportion between the bank's holding of cash and its total of liabilities. If the customer, who has, of course, borrowed the money to use, draws a cheque for £10,000 in favour of another customer of bank A who pays it in to his account, as he naturally would, then bank A's deposits are perma-

nently increased as long as the advance is outstanding. If, as is more likely, the borrowing customer draws a cheque which goes to a customer of bank B, then bank A's deposits go back to their original figure, and £10,000 of its cash at the central bank is transferred through the machinery of the clearing-house from its account to that of bank B; the final result of the transaction is that bank A shows no change in its liabilities, but has changed £10,000 of its cash at the central bank into "loans and advances," so slightly lowering its proportion of cash to liabilities while the bank B has received an addition of £10,000 both to its deposits and to its cash at the central bank.

By the evolution of this system by which the banks can grant credits, which being transferred by cheque from one to another, increase the total of the deposits which they handle, a magical and unlimited power of creating purchasing power is often attributed to them. But in practical fact this power is limited in many countries by law—as in the United States, where the banks are obliged to maintain a certain proportion between cash and liabilities; and even in England where the law leaves the banks free to conduct their business as their prudence and experience directs them, they are always careful to maintain a proportion between cash and liabilities such as is required by safety and by banking conventions. Since the amount of cash at the central bank that is available for them can be varied by the central bank, thanks to its power to contract and expand credit, the policy of the commercial banks is thus closely affected by that of the central bank, though at times when a country's financial position is abundantly strong, the commercial banks, with a comfortable margin between them and the possibility of stringency, have a good deal of latitude in the conduct of their business. The theory, that the banks exercise a despotic tyranny over industry, and by their distribution of credit, decide what is, and what is not, to be produced, is largely a delusion. In spite of amalgamations, competition among them is still so keen that they cannot afford to refuse any solvent customer the accommodation to which his position entitles him; and their dependence on public confidence is so complete and so vital, that they dare not make advances unless they have reasonable confidence that they will be repaid. In granting credits the only question that they can consider is whether the customer's obligation is likely to be met—in other words whether he is going to use the money in some enterprise which will pay, by satisfying some public demand; and so it is public demand, well or ill exercised, which finally decides who is to get credit, and not the banker, who merely interprets it.

The Loans and Advances, by which the banks foster production and trade, are usually the most important item in the assets which they hold being rather more than half of their deposits. At the same time they are the least liquid of their resources, because though nominally recoverable on demand or at short notice, they cannot be called in at times of stringency without inflicting serious inconvenience on customers whose solvency the banks would be most reluctant to endanger. It is thus on the other items in their assets that the banks have to rely, in order to secure that liquid position which is the ideal of prudent banking. Their holding of legal tender cash and cash at the central bank is their first line of defence and after that come the loans at call and short notice which they make to the discount houses, for financing the stock of bills of exchange carried by the latter, and to the Stock Exchange for financing securities that have not yet found a home or are being carried by speculators for the rise. Stock Exchange loans are usually arranged from one settlement to another and so run (in England) for about a fortnight and are less liquid than the loans to discount houses which run from day to day or for a week. It is on these last that the banks, as has been shown, rely at times of seasonal pressure to reinforce their cash holding, calling them in and so obliging the discount houses to produce fresh credit by borrowing from the central bank. The banks' holding of bills of exchange is another highly liquid item because they can arrange so as always to have a certain proportion falling due day by day or any date they may anticipate pressure. Bills of exchange drawn against commodities of general consumption and accepted by banks and firms (*see* MERCHANT BANKERS) of first-rate standing are the most liquid of investments because they do not have to be sold but are paid when due; and the Treasury bills which, since the war caused a huge increase in the floating debt, now form so large a part of the stock in trade of the discount market, have the same advantages with Government security added. The banks' investments—generally a comparatively small item in their assets—are usually confined to Government stocks and other "gilt-edged" securities.

THE NEW YORK MONEY MARKET

The focus of the American money market is New York. There are other subsidiary money centres such as Chicago, St. Louis and San Francisco, but the facilities of these secondary markets are not sufficiently extensive to attract a large volume of funds. The growth of a money market is conditioned not only by the opportunities that it offers for the profitable employment of funds but equally by the facility with which it permits their release. New York offers large possibilities in both directions. Security operations in New York require enormous sums. Flotations of new securities on a large scale for governmental and large private business corporations are handled by New York houses. The annual offering of new securities reaches almost ten thousand million dollars. Between the initiation of such new issues and their final absorption by investors large sums are needed by the officiating bankers, and such sums are normally borrowed. Speculative operations in stocks and bonds in the New York market conducted usually on a marginal basis likewise require great sums.

New York is also the bill and commercial paper market of the country. Dealers in bankers' acceptances have their headquarters in New York city. They buy such acceptances or "bills" as fast as these are created, paying for them mostly with borrowed money, and then turn them over to any bank, firm or individual having free funds to invest. Similarly the commercial paper dealers and brokers have their main offices in New York. So-called "commercial-paper" is made up of the single-name promissory notes of large, nationally known firms who finance some of their operations through the creation and sale of these instruments.

Foreign Exchange Market.—The American foreign exchange market centres are in New York. New York banks and banking houses have large foreign departments. They have branches, agencies, offices or correspondents in the chief centres of the world. Foreign exchange of all kinds and in all forms is bought and sold in the New York market. Most interior banks do not have a large enough foreign business to justify the organization of an independent foreign department. Hence for their foreign business they rely on their New York correspondents. For New York this represents the confluence of innumerable streamlets of foreign exchange business which, however, when finally brought together constitute a mighty tide. Rates determined in the New York market are telegraphed to all interior points and supply the basis on which business is done. The conduct of the foreign exchange business, however, requires the constant maintenance in New York of large balances belonging to interior institutions.

New York's position of leadership in manufacturing and commerce contributes to its financial leadership. It is not only the chief manufacturing city of the country but also the principal port, the leading city in wholesale distribution, and the centre of the printing and publishing trades. Large sums are constantly needed in New York to finance its manufactures, its domestic and foreign commerce and its output of newspapers, magazines and books.

Structure of the New York Money Market.—The foundation of the money market is naturally the Federal Reserve system. This system holds the underlying reserves of gold and of other "lawful money." It supplies currency when there is need for it. It supplies gold for export and makes imports of gold available for domestic credit operations. The main dealings of the Federal reserve banks are with member banks and with the Government, although they also carry accounts for foreign banks, and, for exchange and check collection purposes, with domestic, non-mem-

ber banks. They may also engage in open-market operations in bankers' acceptances and in governmental securities. The active conduct of affairs on the supply side of the money market is, however, primarily the affair of the ordinary banks. These are national banks, organized under Federal law, and State banks and trust companies chartered under the laws of New York State. Besides the large banks and trust companies there are also agencies of foreign institutions and domestic and foreign private banking firms of all kinds.

Related Agencies.—Mention must be made of the related agencies. There are money brokers who act for the banks on the floor of the stock exchange; there are acceptance firms and dealers who, for a small commission, help to create, assemble, distribute and perhaps again subsequently to turn over, acceptances in the market; there are the commercial paper houses and the dealers who handle the marketing of single-name promissory notes. Finally reference may be made to a fringe of individual money brokers and middle-men who function as intermediaries between borrowers and lenders.

On the demand side of the market the alignment is equally diverse. First may be mentioned the stock exchange brokers who finance their customers' marginal operations. From 50 to 80% of the funds needed by the brokers for this purpose are obtained from the market in call and time loans. On the demand side also are arrayed the bond and security dealers. They not only arrange for financing new issues but also carry on extensive over-the-counter bond trading. They are heavy borrowers from the banks. The acceptance dealers also figure primarily on the demand side. They borrow on call or on time from the banks and in times of unfavourable money rates they may get direct relief from the Federal reserve bank through the open market.

Classed with the acceptance dealers are the commercial paper houses. They too have to borrow in order to carry their lines of paper pending its final sale to the ultimate purchaser. Finance companies of divers kinds also play a considerable rôle in the market. They handle "instalment" or "conditional sales" paper arising in sundry fields. They finance the dealers in automobiles, pianos, radios and numerous other articles sold in America on the instalment plan.

Lastly may be mentioned the host of other corporations, firms and individuals who require funds. These borrow to some extent on stock exchange collateral, on the security of warehouse receipts covering the great staples, or on some other satisfactory form of property. The prevailing American practice in such firm or individual borrowing, however, is based upon the extension of unsecured "lines" of credit involving the use of the single-name promissory note.

Operation of the New York Market.—The most sensitive element in the New York market is the "call-money" market. Call loans are made principally on stock exchange collateral but to some extent, also, on bankers' acceptances and other acceptable security. They may be negotiated directly with the banks, or obtained through money brokers or at the "money desk" in the stock exchange. The nature of the call loan makes it a very satisfactory short-term investment for the lender. It is not only amply secured but is, as well, subject to repayment at the lender's request. Rates on call loans are relatively low due to the narrowness of the field in which they can be employed as compared with the abundance of funds the market supplies. Owing to the highly competitive nature of the market call rates are extremely sensitive. The money flowing into the call market is made up of temporary surpluses. This money comes from all over the country. While call loans are extended through the New York banks, in many cases these act simply as the agents of out-of-town banks or of other customers. Indeed, the New York institutions often lend in the stock market more of out-town money than they do their own. The members of the stock exchange are also heavy borrowers of time money. These borrowings may be arranged through the money brokers or they may be negotiated by brokerage firms with their own banks.

Acceptances.—Less sensitive than the call-money market is the bill market. This is the market in which primarily bankers' acceptances, but to a slight extent also so-called "trade acceptances," are dealt in. The foundation for the bill market was laid by the Federal reserve act. The market has been built up since 1916. In 1928 acceptances outstanding exceeded one thousand million dollars. Acceptance procedure has developed primarily in connection with foreign trade, but a beginning has been made in applying it also to domestic trade. Acceptances are ordinarily purchased by dealers who offer them for sale to banks, firms and individuals with funds to invest. The bills may change hands several times before maturity. The rate at which acceptances are discounted is spoken of as the "open-market" rate and it is determined by competitive conditions of demand and supply.

The reserve banks are heavy buyers of acceptances. These institutions have constantly endeavoured to develop the acceptance market. They stand ready to take eligible bills without limit at the open-market rate. Dealers in acceptances are thus never left with an unsold surplusage. This attitude on the part of the reserve banks assures the maintenance of an open market. Member banks themselves will often sell holdings of their bills to the Federal reserve banks to replenish reserves. The acceptance market thus helps to promote general flexibility of the credit system.

As one branch of the money-market the acceptance market is strongly influenced by competitive conditions in the call-money market. Funds tend to be diverted from the acceptance market when alluringly high rates prevail in the call market. After a time, however, acceptance rates are sympathetically affected.

The Commercial-paper Market is less important than the "bill" or the acceptance market. The commercial-paper market is peculiar to the United States. Its stock-in-trade is the single-name promissory note issued by large prospective borrowers. Only names of nationally known firms will suffice to give currency to this type of paper in the market. The commercial-paper market is not open in the sense that notes once sold are again offered for sale. In the great majority of cases paper is held by the purchasers until maturity. Promissory notes are primarily attractive to those having funds to invest for a reasonable period of time. The commercial-paper rate is naturally higher than the call money or the bill rate, but it is also steadier.

Government Securities.—Another important factor in the operation of the money market is the government securities market. This division of the money market developed its great significance after the World War. Since then Government finance has been on a stupendous scale. Periodically the Government requires large sums not only for current expenditure but for refinancing, and for the funding of floating obligations. These operations provide a large turn-over in the market. Government receipts and expenditures are so enormous that it also often becomes necessary to issue large amounts of treasury bills in anticipation of revenue. These bills find a ready market and form in consequence a very satisfactory form of temporary investment. The liquidity of Government securities has been greatly stimulated by legal provisions which permit member banks to borrow from the reserve banks, using such securities as collateral and which further permit the reserve banks themselves to buy and sell these governmental issues as considerations of policy may warrant.

The Securities Market in the United States also plays an important rôle in money-market procedure. Reference has already been made to the heavy borrowings by brokers and dealers in investment securities. But beyond this the system of daily settlements on the stock exchange offers attractive opportunities for liquid temporary investments for others. The banks themselves are heavy purchasers of securities. A marked development in this direction has been stimulated by the growth of so-called time deposits—for the withdrawal of which from the banks a 30 day notice by the depositor is necessary. But business firms and individuals also invest temporarily idle working capital in bonds and even in stock, relying on the fact that, subsequently, when such capital is again required for ordinary business operations, these investments can be promptly sold. The security markets thus offer an enormous reservoir, into which idle funds can be drained, and from which, when occasion demands, they can again be pumped.

American Banking Abroad.—The development of American

banking abroad has also profoundly affected the domestic money market. American banks are purchasers of foreign bills and in other ways as well lend funds in foreign centres. There is a considerable shifting of funds back and forth from one international market to another according to the competitive lure of the respective discount rates and the state of the exchanges. In like manner foreign banks buy American bills and carry heavy New York balances. These operations swell the flow and ebb of funds in New York.

Procedure in the New York market is very flexible. Through the effective clearing and transfer system operated by the Federal reserve banks large sums can be rapidly shifted to and from New York. A slackening of demand for funds in the interior thus leads quickly to their transfer to New York where they can be profitably loaned or invested. An increased interior demand for funds is similarly accompanied by a rapid withdrawal from New York. The New York market may thus be regarded as the great national money shock-absorber.

Federal Reserve System.—The Federal reserve system plays an important part in this procedure. Allusion has already been made to its clearing and transfer operations. As pressure develops in the money market the reserve system can be turned to for relief. Member banks may borrow from the reserve banks by giving their own notes secured by U.S. Government issues and by eligible bills. They may also rediscount paper drawn from their portfolios. Additional reserve funds are also supplied to the market indirectly: (*a*) when the government borrows from the reserve banks to meet maturing obligations or to obtain working funds. As these funds are paid out they tend to return subsequently through depositing by the payees, as a part of the member banks' reserve account; (*b*) when bills are sold to the reserve bank through the open market, the funds used to pay for these bills tending also to get into member banks' reserve balances; (*c*) when dealers in U.S. securities sell such securities to the reserve banks under so-called "repurchase agreements"; (*d*) when the reserve banks themselves take the initiative in adding to their holdings of bills and securities.

Supervision.—The Federal reserve system, like other central banks is, at least to some extent, in a position to supervise and to safeguard the money market. The reserve system cannot control operations in detail. It cannot, for example, lend at all in the security markets. The member banks must assume full responsibility for loans to brokers and dealers in connection with investment and speculative operations in securities. But through the control of final reserves and of the discount rate the reserve system may determine the conditions under which member banks can get funds for further expansion. Through its open market operations it can also directly influence the volume of reserve bank credit available. Through its wide powers in foreign operations relating to foreign exchange and to gold movements it can act to safeguard the basic reserve position. Although there are 12 independent reserve banks the important open market operations are conducted mainly through the New York market by a committee representing the system as a whole. Similarly, the exercise of its supervisory powers by the Federal reserve board has tended to give unity in discount procedure. The reserve system thus acts as the foundation of the money market, and as its supervisor and protector. (E. E. A.)

MONFALCONE, a town, province of Trieste, Italy, 20 m. N.W. of Trieste by rail. Pop. (1921) 9,659 (town), 11,838 (commune). It is crowned by the remains of a castle, an important point in the Great War. Its shipbuilding yards have been rebuilt, and it also produces sodium carbonate, and refines oils. About a mile from the castle of Duino, 5 m. to the south-east, the Timiavo (anc. *Timavus*) emerges from its subterranean course of more than 25 m. from the caves of S. Canziano by three different exits in normal times, and by seven in flood time. (Virgil, *Aeneid*, i. 244 speaks of nine.) This natural phenomenon had naturally attracted the attention of the ancients, and their writings are full of allusions to it; there has, it appears, been little change since ancient times. There was a temple to the river god on the site of the old church of S. Giovanni di Duino.

See *The Year's Work in Classical Studies*, 1925–26, 117, 118.

MONFORTE or MONFORTE DE LEMOS, a town of north-western Spain, in the province of Lugo, on the Cabe, a small right-hand tributary of the Sil, and at the junction of the railways from Tuy and Astorga to Corunna. Pop. (1920), 14,076. Monforte is built on a hill surmounted by a ruined mediaeval citadel; it has manufactures of soap and linen, and some trade in livestock.

MONGE, GASPARD (1746–1818), French mathematician, the inventor of descriptive geometry, was born at Beaune on May 10, 1746. He was educated first at the college of the Oratorians at Beaune, and then in their college at Lyons. He was a draftsman in the practical school attached to the military school at Mézières.

In 1768 Monge became professor of mathematics, and in 1771 professor of physics, at Mézières; in 1780 he was appointed to a chair of hydraulics at the Lyceum in Paris (held by him together with his appointments at Mézières), and was received as a member of the *Académie;* his intimate friendship with C. L. Berthollet began at this time. In 1783, quitting Mézières, he was, on the death of É. Bézout, appointed examiner of naval candidates. Although pressed by the minister to prepare for them a complete course of mathematics, he declined to do so, on the ground that it would deprive Mme. Bézout of her only income, from the sale of the works of her late husband; he wrote, however (1786), his *Traité élémentaire de la statique.*

Monge contributed (1770–1790) to the *Mémoires* of the Academy of Turin, the *Mémoires des savants étrangers* of the Academy of Paris, the *Mémoires* of the same Academy, and the *Annales de chimie,* various mathematical and physical papers. Among these may be noticed the memoir "Sur la théorie des déblais et des remblais" (*Mém. de l'acad. de Paris,* 1781), which, while giving a remarkably elegant investigation in regard to the problem of earth-work referred to in the title, establishes in connection with it his capital discovery of the curves of curvature of a surface. The memoir gives the ordinary differential equation of the curves of curvature, and establishes the general theory; but the application to the interesting particular case of the ellipsoid was first made by him in a later paper in 1795.

In 1792 Monge became minister of marine, but he remained so only until 1793. When the Committee of Public Safety made an appeal to the savants to assist in producing the *matériel* required for the defence of the republic he applied himself wholly to these operations, and distinguished himself by his indefatigable activity; he wrote at this time his *Description de l'art de fabriquer les canons,* and his *Avis aux ouvriers en fer sur la fabrication de l'acier.* He took a very active part in the measures for the establishment of the normal school (which existed only during the first four months of the year 1795) and of the Ecole Polytechnique and was at each of them professor for descriptive geometry; his methods in that science were first published in the form in which the shorthand writers took down his lessons given at the normal school in 1795, and again in 1798–1799. His later mathematical papers are published (1794–1816) in the *Journal* and the *Correspondance* of the polytechnic school. On the formation of the Senate he was appointed a member of that body, with the title of Count of Pelusium; but on the fall of Napoleon he was deprived of all his honours, and even excluded from the list of members of the reconstituted Institute. He died at Paris on July 28, 1818.

See B. Brisson, *Notice historique sur Gaspard Monge;* Dupin, *Essai historique sur les services et les travaux scientifiques de Gaspard Monge* (Paris, 1819), which contains (pp. 162–166) a list of Monge's memoirs and works; and the biography by F. Arago (*Oeuvres*, t. ii., 1854).

Monge's various mathematical papers are to a considerable extent reproduced in the *Application de l'analyse à la géométrie* (4th ed., last revised by the author, Paris, 1819); the pure text of this is reproduced in the 5th ed. (revue, corrigée et annotée par M. Liouville) (Paris, 1850), which contains also Gauss's Memoir, "Disquisitiones generales circa superficies curvas," and some valuable notes by the editor. The other principal separate works are *Traité élémentaire de la statique, 8e édition, conformée à la précédente, par M. Hachette, et suivie d'une note, etc., par M. Cauchy* (Paris. 1846); and the *Géométrie déscriptive* (originating, as mentioned above, in the lessons given at the normal school). The 4th edition, published shortly after the author's death, seems to have been substantially the same as the 7th (*Géométrie descriptive par G. Monge, suivie d'une théorie des*

ombres et de la perspective, extraite des papiers de l'auteur, par M. Brisson (Paris, 1847).

MONGHYR, a town and district of British India, in the Bhagalpur division of Behar and Orissa. The town is on the right bank of the Ganges, and has a railway station. Pop. (1921) 46,825. Monghyr, which appears under the form of Mudgagiri in an inscription of the 9th century A.D., was, under the Mohammedans, a place of military importance and frequently the seat of local governors or commandants. Shah Shuja built himself a palace here and in 1761, Nawab Mir Kasim Ali moved his capital here from Murshidabad. The walls and ramparts of the fort are still standing and give Monghyr a unique appearance among the towns of Behar. The fort dates back beyond 1580, when it was repaired by Todar Mal, Akbar's general and governor. Inside it is the tomb of an unknown saint erected in 1497. The house of Gurghin Khan, the Armenian general of Mir Kasim Ali, stands on a small hill 3 m. east of the town. Monghyr was captured by the British in 1763, and it was here that, three years later, Clive quelled "the White Mutiny" of the European officers of the army. Monghyr was formerly famous for its manufactures of firearms, swords and iron articles of every kind. Its chief industry now is the manufacture of cigarettes, which is carried on in a factory of the Peninsular Tobacco company, which employed nearly 3,000 hands in 1925.

The DISTRICT OF MONGHYR has an area of 3,927 square miles. The Ganges divides it into two portions. The northern, intersected by the Burh Gandak and Tiljuga, two tributaries of the Ganges, is a flat, closely cultivated country, subject to inundations. There are many marshes, of which the largest is the Kabar Tal (7 sq.m.). To the south of the Ganges the country is dry and much less fertile, and irrigation is necessary. Some ranges of hills and isolated plains occur in this part of the district. The chief are the Kharagpur hills with a length of 20 m., and an average breadth of 24 m. which rise at Maruk to 1,628 ft. above sea-level, and the Gidheswar (or Gidhaur) hills, which cover about 80 square miles. At Jamalpur (pop. 24,827), 6 m. from Monghyr, are the engineering workshops of the railway company which employ 11,000 workmen. Slate is quarried in the Kharagpur hills; the output in 1921 was nearly 3,000 tons.

MONGOL CAMPAIGNS. This article deals with the military methods of the Mongols during their great period of conquest, and illustrates it by an outline of the chief campaigns in that brief but unparalleled span of 30 years wherein they overran the Asiatic and European continents from the Yellow sea to the Baltic and the Adriatic.

If we study a physical map of Asia and Europe, we can trace a vast belt of open and level territory, though of varying altitudes, which stretches from the Yellow sea in the Far East to the Baltic sea and the Danube in the West. This chain of plains and plateaux is practically unwooded, and only broken by a few well-defined mountain ranges. It is the trough of the world's migrations, the path by which the great racial invasions have come to Europe and to China. Along it have passed the transcontinental routes of commerce, from the early caravans to the Siberian railway. But in even greater volume has it been the channel for armies, for it offers few obstacles to movement, and there uniquely the paramount principle of mobility has full rein.

In the centre of the continent lies the Mongolian plateau, barred by lofty and inaccessible Tibet from the fertile plains of India, but with comparatively easy access to the rich fields of China to the East, and of Western Turkistan and Russia to the West. This bare, bleak enclosure is the birthplace of the Turco-Mongol race, and the conditions of their environment have given the race their special characteristics. The European peoples became seafarers by reason of their lengthy coastlines and close touch with the sea. The Mongolian peoples became horsemen because constant and far-reaching land movement was necessary to obtain pasturage, and a warlike race because the barrenness of the land and the resulting migrations brought them into repeated conflict with other tribes and peoples. Long before the days of Jenghiz Khan, this lateral expansion of the Turco-Mongol race, and their pressure on the peoples who lay to the west, had produced barbarian invasions which overran Europe and overthrew the Roman empire, culminating in the invasions of the Huns.

Organization and Equipment.—Fuller knowledge has dispelled the excuse of mediaeval historians that the Mongol victories were due to an overwhelming superiority of numbers. Quality rather than quantity was the secret of their amazingly rapid sequence of successes. Alone of all the armies of their time had they grasped the essentials of strategy, while their tactical *mechanism* was so perfect that the higher conceptions of tactics were unnecessary.

The supreme command was in the hands of the emperor; but once the plan was decided upon, the subordinate generals executed the actual operations without interference, and with but the rarest communication with the supreme command. The nominal command of the various armies was held by royal princes, but the actual control was exercised by generals of experience, of whom the most famous were Chépé and Sabutai in the western campaigns, and Mukhuli in China.

The organization of the army was on a decimal basis. The strongest unit was the touman, a division of 10,000 troops, which could act as an independent force. The army was made up by a temporary grouping of toumans, generally three. Each touman was composed of 10 regiments of 1,000 men, and each regiment of 10 squadrons, and that again was divided into 10 troops of 10 men apiece. In addition there was a touman *d'élite,* the guard, which usually formed a general reserve in the hands of the commander-in-chief. There were also various formations of auxiliary troops.

For their protective equipment the Mongols had an armour of tanned hide in four pieces, composed of overlapping plates, which were lacquered to prevent humidity. The shield was only used when on sentry duty. Their weapons comprised a lance, a curved sabre with sharpened point, suitable either for cutting or thrusting, and two bows—one for shooting from horseback, and the other, for greater precision, when on foot. They had three quivers, each with a different calibre of arrows for the various ranges. One class could penetrate armour, and the other was suitable against unprotected troops. In addition, their light artillery consisted of various missile-throwing machines, mangonels, and catapults. These were taken to pieces, and formed a pack-artillery. They could fire rapidly and accurately, could go anywhere, and were adequate for open fighting.

Every trooper carried a complete set of tools, individual camp-kettle, and iron ration, for his own maintenance and subsistence in the field. He had also a water-tight bag in which he carried a change of clothes, and which could be inflated for crossing rivers.

Tactics.—The tactics of the Mongol army were rigid in conception, without the possibility of wide variation, but flexible in execution. They were built up on a definite framework of tactical moves, so that they resembled an applied battle drill. The analogy is further heightened by the fact that the different manoeuvres were directed by signals, so that the delays and upsets caused by orders and messages were obviated. The result of these battle drill tactics was seen in an amazing perfection and rapidity of execution. The Mongol force was a machine which worked like clockwork, and this very mobility made it irresistible to troops far more strongly armed and numerous.

The battle formation was comprised of five ranks, the squadrons being separated by wide intervals. The troops in the two front ranks wore complete armour, with sword and lance, and their horses also were armoured. The three rear ranks wore no armour, and their weapons were the bow and the javelin. From these latter were thrown out mounted skirmishers or light troops, who harassed the enemy as he advanced. Later, as the two forces drew near each other, the rear ranks advanced through the intervals in the front ranks, and poured a deadly hail of arrows and javelins on the enemy. Then, when they had disorganized the enemy ranks, they retired into the intervals, and the front ranks charged to deliver the decisive blow. It was a perfect combination of fire and shock tactics, the missile-weapon troops firing and disorganizing the enemy ready for the

shock troops to complete his overthrow.

Their continuous run of victories, usually over superior numbers, were achieved in defiance of most of the canons on which European armies, of the present equally with the past, have based their systems. Nor can these successes be discounted in the way that is common when discussing victories over Asiatic troops, who are regarded as lacking the staying power, discipline, and equipment of European soldiers. Sabutai's warriors proved themselves more than a match for the men-at-arms of mediaeval Europe, who had superiority both of numbers and armour. The Mongol tactics were never to close with the adversary until he was weakened and disorganized by fire. If charged by the heavy European cavalry, they never let themselves be drawn into a clash, but dispersed on a signal, rallied by signal at a distance, and again assailed the enemy with fire, repeating the process until the enemy was "unhinged" and the way paved for a decisive charge. Thus they proved that mobility is the basis of tactics, as of strategy; that lightly armed troops can beat more heavily armed ones if their mobility is sufficiently superior.

Another canon that they violated was that mobile troops, such as cavalry, must needs rest on a stable infantry base. Although cavalry was the decisive arm alike of Alexander and Hannibal, it formed merely the mobile wings hinged on an essentially protective infantry centre, which was the pivot on which it manoeuvred. The prime feature of the Mongol military system was therefore its simplicity, due to the use of a single arm, in contrast to the inevitably complex organization of a combination of several arms which has always characterized European armies. In this way the Mongols solved the ever-difficult problem of co-operation between arms which had radically different qualities and limitations. The single arm they used was that which possessed the highest degree of mobility, and in this lay the secret of their unbroken run of victory. At such local points where greater "locomobility" was needed than mounted troops could achieve, a proportion of the troops were temporarily dismounted and fought on foot.

Invasion of China.—The career of the founder of the Mongol power, Jenghiz Khan, is recounted in the article upon him. After he had established his overlordship over the nomads of the Mongolian steppes, his first major campaigns were in the conquest of the Kin empire in China, 1211–14. He had previously loaned the emperor troops and thereby gained an intimate knowledge of the country and conditions within the Great Wall.

The first invasion, of 1211, was probably not made in much strength. It passed through the wall without difficulty, one of the entrances being opened by treachery, and dispersed the advanced forces of the empire. Then one of the Kin armies was trapped in hill country which it knew less well than the invaders, and Chépé's touman, making a night march round and on to its rear, broke it up. But as the invaders penetrated deeper they found the fortified cities an almost insuperable obstacle both to their methods and to their small numbers, and, in face of the growing strength of the enemy forces, withdrew in the autumn. Next spring this invasion was renewed and this time Jenghiz Khan appears to have used Taitong-Fu as a bait, in the same way as Bonaparte used the fortress of Mantua in 1796—to draw on and annihilate the successive armies which came to its relief. But the reduction of fortified cities remained an obstruction until the campaign of 1214. Then a vast concentric advance by three armies, the centre one moving on to the sea in the rear of Yen-Kin, the Kin capital, brought about such a demoralization that the emperor fled to the south and the chaos in his dominions enabled the Mongols to subdue the disorganized fragments. Leaving his general Mukhuli in control in China Jenghiz Khan himself returned to Karakorum. With his borders now firmly established as far as the river barrier of the Hoang-Ho, his base was secure for an advance towards the west. Here lay the rich and fertile empire of the Shah of Khwarizm (Karismian empire), which embraced what is to-day Turkistan, Persia, and northern India. The Shah's intrigues, combined with Jenghiz Khan's desire for expansion, brought about a conflict, the signal for which was the Shah's folly in putting to death the envoys of Jenghiz.

Invasion of Turkistan.—Like all the Mongol campaigns, the invasion of Turkistan was prepared by the employment of an extensive spy system, combining propaganda among the enemy peoples with a remarkable service of information to the Mongol command. The Shah mobilized all his vassal States, but like Napoleon's opponents in the disposition of his forces he adopted the fatal cordon system. By stringing out his forces in packets all along the line of the Syr Daria, he made himself weak everywhere and restricted himself to a purely defensive rôle.

Then, early in 1220, Jenghiz Khan struck his opening blow, a shrewdly conceived diversion. Chépé, with two toumans, had passed by the southern route from Kashgar into Fergana, and was advancing on Khojent, which covered the southern end of the Syr Daria line. Thus Chépé directly threatened the Shah's right flank, as well as Samarkand and Bukhara, which lay beyond—the two centres of his power. It was a dagger pointing at the heart of the enemy. The Shah reinforced the Syr Daria line, and concentrated some 40,000 at Bukhara, and also at Samarkand. Against this Karismian total of some 200,000 men the Mongols had probably about 150,000 in the invading armies.

Jenghiz Khan had distributed his main striking force into three armies, two under his sons Juji and Jagatai. While Chépé was striking his first blows in Fergana, the three armies which formed the main force traversed a northern route by the Dzungarian Gate, and in February suddenly debouched on the left flank of the Syr Daria line. The two armies of Juji and Jagatai turned south from Otrar, clearing the line of the Syr Daria, capturing the fortresses, and working towards Chépé's detachment, which, after taking Khojent, was seeking to join hands with them. Then, like a thunder-clap, as the Shah's attention was fixed to his front, the news reached him that Jenghiz Khan with his mass of manoeuvre had appeared on his left rear, and was almost at the gates of Bukhara.

This army of 40,000 men, under Jenghiz Khan himself, had followed in the wake of Juji's and Jagatai's armies, crossed the Syr Daria at Otrar, and then disappeared. Masked by the armies of the two princes, its arrival on the scene had passed almost unnoticed. Having crossed the Syr Daria, it vanished into the immense desert of Kizyl-kum. By this dramatic venture of 40,000 to 50,000 men, and even more horses, across a desert, Jenghiz Khan appears to have gained complete secrecy until the moment when he debouched at the southern end and was almost on the top of Bukhara—in rear of the Shah's armies! At one blow the Shah's whole line was turned, and his communications severed with his more distant westerly States, whose forces had still to arrive. Demoralized, the Shah fled and left the garrison of Bokhara to its fate.

Jenghiz Khan captured Bukhara, and then turned east towards Samarkand. Meanwhile, the armies of the princes had joined hands with Chépé, and were converging on Samarkand. The doomed last stronghold of the Karismian power was caught between the hammer of the princes and the anvil of Jenghiz Khan himself, and soon fell. In the brief space of five months Jenghiz Khan had overthrown the mighty Karismian empire, and opened the gateway to the west, towards Russia and towards Europe.

The enemy armies crushed, Jenghiz Khan despatched Sabutai and Chépé westwards in pursuit of the Shah and to open up the path to further conquests. The Shah's son, Jelaladdin, still held out in the south for a time, and then crossed the Indus. Jenghiz followed him up, and in 1221 sent an expedition to Delhi, which took nominal possession of the country that his successors were to hold in reality. Jenghiz devoted his remaining years until his death to consolidating his mighty empire, which stretched from Korea to the Persian gulf.

Invasion of Russia.—Sabutai and Chépé, after accomplishing their mission of pursuit, asked permission for an advance towards the Kiptchak country—*i.e.,* southern Russia. The suggestion found favour with the emperor, and in six months they had advanced as far as Tiflis, crushing the kingdom of Georgia. In the spring of 1221 they pressed on into south Russia as far as the basin of the Donetz. Everywhere they established a stable

military and civil administration. Further, they organized an elaborate system of information to discover the weak points and rivalries of Europe. In this they found the Venetians quite willing to sacrifice the interests of Christian Europe in order to gain an advantage over their great trading rivals, the Genoese. In return for Mongol help in ousting the Genoese trade-centres in the Crimea, the Venetians acted as part of the intelligence service of the Mongols.

In 1223, however, Sabutai and Chépé were recalled by Jenghiz Khan, and returned by the northern end of the Caspian sea. Schemes of European conquest were suspended for a generation owing to the death of Jenghiz Khan in 1227. Disputes over the succession, for which Jenghiz had designated his second surviving son Ogdai, retarded further expansion to the West. Jenghiz Khan had called to his aid, in the administration of the immense newly gained empire, Yeliu Chutsai, a statesman of the former Kin empire. The natural result was to give a Chinese complexion to the policy of the Mongol empire, and to discourage adventures in Europe. But eventually Sabutai's scheme for the invasion of the West came to the front once more. The ground had already been prepared for it by his network of spies and propagandists.

It is probable that the invading force did not number more than 150,000 men, even when it set out, and that as a result of the losses in the preliminary campaigns and the detachments left to guard the communications with the East, little more than 100,000 took part in the Polish and Hungarian campaigns. The troops themselves came mainly from China, as the occupiers of the former Karismian empire were needed for events there. The horses only could be provided from south Russia, which had been organized as a vast remount depot.

In 1239 Central Russia was subdued as far as Moscow, and security was assured to the rear and communications of the invaders. The real objective was Hungary, for its people were the only branch of the Turco-Mongol race who still remained outside the authority of Jenghiz Khan's successors. But the neighbouring powers concerted, if not combined, to resist the invasion. They included Poland, Bohemia, and the Holy Roman empire, to which Hungary acted as a bulwark. With these powers were arrayed the German military orders, whose mission it was to be the outposts of the West against the heathen.

Szydlow and Liegnitz.—In Jan. 1241 Sabutai, with the prince Batu as his nominal superior, concentrated the Mongol forces in the region Lemberg-Przemysl. His intention was to force the passes of the Carpathian barrier, and to march on the Hungarian capital, Gran. But whilst he thus made his main effort against the principal enemy, it was necessary to assure security against interference from the others. An advance into Hungary, with the Poles and Germans ready to fall on his right flank, would be hazardous. It was necessary to crush these threats to his flank, and to ward off any premature intervention from Austria (the empire) or Bohemia. The tremendous victories of Szydlow in Poland and Liegnitz in Silesia have caused some historians to imagine that the Mongol purpose was a general conquest of Europe. But it was no part of Sabutai's strategy to advance into the hilly and wooded regions of western Europe, where the Mongolian horsemen would be at a disadvantage, and their system of tactics unsuitable to the country. The plain of Hungary was his goal, and he kept to it unswervingly.

He divided his force into four armies. Three of these he assigned to the main operation, and the fourth he used to achieve his secondary object—the removal of the danger on his right flank. This army, under Kaidu, moved first, as had Chépé's detachment into Fergana. At the beginning of March 1241 it crossed the Vistula at Sandomir. Then it fell upon the Polish armies of Boleslas and Miecislas at Szydlow and crushed them. Kaidu swept on at hurricane speed, took Cracow, and then Breslau; on April 8 he met at Liegnitz the German forces under Duke Henry of Silesia, together with the orders of the Templars and Hospitallers, and the remains of the Polish troops. A day's march to the south was the army of King Wenceslas of Bohemia. The Mongols, who were inferior in numbers to the troops of Duke Henry, struck on April 9 before the allied armies could effect a junction, and inflicted a terrible disaster. In less than a month the Mongols had covered some 400 miles, fought two decisive battles, taken four great cities, and conquered Poland and Silesia from the Vistula to the borders of Saxony.

Advance into Hungary.—But while they had been fulfilling this mission of security, Sabutai had wiped out the Hungarian army. He advanced into Hungary in three columns, of which the two flank columns traversed the circumference of an elongated circle, while he himself with the central mass started later and went through the diameter Thus he set up his forces in a close-linked and secure system with true economy of force, as was later the Napoleonic method. The dates of departure and the routes were evidently so arranged that the three columns should converge and join hands on the Danube near the Hungarian capital, where the main enemy forces were likely to be met.

The central mass—the last to move—forced the pass of Ruska on March 12, and advanced by the valley of the Theiss to the Danube near Gran. Rarely, if ever, in history has the speed of its advance been approached. Sabutai's advanced guard arrived at the Danube on the 15th, and Sabutai himself with the main body came up two days later. Within a fortnight all three armies had assembled, and Sabutai confronted Bela of Hungary, whose army lay across the Danube.

At this moment, however, Kaidu's detachment had yet to fight the battle of Liegnitz, and Sabutai would be uncertain of the situation as regards the other enemy armies. Moreover, it would have been difficult for him to force the crossings of the river under the eyes of the enemy, nor would it have been wise to fight a decisive battle with the Danube at his back. Hence he executed a true strategic retreat towards his base at Munkacz, luring on his enemy away from the protection of the Danube and the chance of reinforcement. The retirement was carried out slowly, taking six days to reach the Sajo river, half the distance. Then suddenly he delivered his crushing surprise blow. In the night he crossed the Sajo (*q.v.*), and at daybreak he struck. By midday the Hungarian army ceased to exist, Bela was in flight, and more than 70,000 of his men were left dead on the battlefield.

For this battle we have accounts sufficiently reliable to grasp the Mongol tactics. Contemporary observers were impressed, above all, by two features: first, the speed, silence, and mechanical perfection of their evolutions carried out by signals with the black-and-white flags of the squadrons; second, the deadliness of their fire. Their opponents, in the words of a chronicler, "fell to the right and left like the leaves of winter." The armies of the middle ages, until the English archers in the next century, relied almost entirely on shock tactics. But the Mongols, as Plano Carpini says, "wounded and killed men and horses, and only when the men and horses are worn down by the arrows, do they come to close quarters."

After this holocaust, Hungary was occupied without further fighting. There was no attempt to push farther into Europe, apart from one reconnaissance into Austria. But at the end of the year Ogdai died at Karakorum, and the princes were all eager to compete for the succession. As a result the Mongol armies and their leaders decided to return east. The evacuation of Hungary was carried out systematically and without interference, and Europe, wondering at its deliverance, began to enshroud both the causes of its defeats and the strength of its conquerors in a cloud of legend.

(B. H. L. H.)

MONGOLIA, the name given to a vast tableland in Central Asia, the traditional home-country of the Mongol peoples and formerly a definite "dependency" of the Chinese Empire, but now divided into two very distinct cultural and political entities, Inner Mongolia, which is becoming absorbed into China, and Outer Mongolia, a republic in close relations with the Russian Soviet Federation. The later stages of the political evolution and the significance of the present situation can most easily be appreciated in the light of the physical geography of the country, its natural divisions and their respective orientation.

Mongolia in the physical sense is essentially a plateau varying from 3,000 to 5,000 feet in altitude and composed of granites, gneisses and crystalline schists of Archean and Primary age. It

is bordered on the north-west by the extensive mountain-complex of the Altai, Tannu-ola and Sayan groups, and on the north-east by the Trans-Baikalian Highlands. On the south-east it is separated from the Plain of north China by a belt of pronounced scarps whose continuation northwards in the high faulted scarp of the Great Khingan delimits the plateau on the side of Manchuria. On the south-west it abuts against the lofty Nan-shan, the outermost of the great chains which enclose the Tibetan plateau. Only on the west does the Mongolian tableland sink to lower levels in the Jungarian depression and the Tarim basin on either side of the Tien-shan. Physiographically Mongolia falls into three clearly marked divisions:—

1. The central or Gobi region (*see* also under Gobi) on the whole the lowest and most uniform portion of the plateau. It forms an elongated shallow depression within the plateau and has as its rim on the south-east and east the plateau-edge formed by the In-shan series of scarps in Inner Mongolia and the faulted scarp-edge of the Great Khingan; while on the north-west it is delimited by the sloping edge of the broad Altai-Khangai-Kentei mountain-complex. It thus runs with successive decrease of altitude from the foothills of the western Nan-shan in the south-west to the Khingan foothills in the north-east. Isolated and weathered hill-ranges of low altitude characterize the surface of Gobi, which is generally covered with gravel, sand or even marked by bare rock. Rivers are absent save on the northern margin where the Kerulen drains an area really foreign to Gobi—an area of mountains and valleys constituting the first outliers of the Yablonoi mountain-system of Trans-Baikalia.

2. The north-western mountain-complex which has been compared in its character with the Bohemian block in Europe. It is in the nature of an uplifted massif enclosed by mountain ranges (Altai, Khangai, Sayan) in places marked by faulting. It may even be the counterpart, on a smaller scale, of the Tibetan plateau. The general level of the valleys in this region is about 3,000–4,500 feet above sea-level. The whole is well drained by rivers, some of which, *e.g.*, the Kobdo and Tess, enter brackish or salt lakes with no outlet. The largest lake, the Kosso-gol (5,320 feet), close to the Siberian frontier, occupies the highest part of this mountainous region. At least two high basin-areas can be distinguished: a. That of the Yenisei headstreams (or Urianghai basin); entirely mountain-girt by the Sayan on the north, the Tannu-ola on the south. The floor is dissected by rivers but is nowhere less than 1,700 ft. in altitude. b. A series of lake-basins at different levels contained between the Tannu-ola and Altai further south. These are remnants of larger lakes which have shrunk as the result of progressive desiccation. The largest is Ubsa Nor, occupying an extensive plain, while further south is Kirghiz Nor, and a third group round Kobdo (Kaira Ussa and Durga Nor). This sub-region is one of lofty gravel plains penetrating north-westward between the Khangai and Altai. The latter mountain range (or series of ranges) rises abruptly out of the Jungarian depression, in which its southern base lies at an altitude of only 1,000–3,000 feet, to heights of 10–11,000 feet (decreasing eastward). The northern base of the Altai rests on the high plateau at a considerable height (4,260 ft. at Kobdo). Thus the long steep southern scarp-face and the short northern slope to the high plateau behind give this system the character of a series of tilted fault-blocks. The Kentei and other mountain ranges to the west of Urga seem partly to enclose the basin formed by the headstreams of the Selenga-Orkhon.

3. South-eastern Mongolia, on the inner or Chinese side of the Gobi, is like the north-west in being much more diversified in character than the central portion of the plateau. It contains an outer and an inner series of chains. The outer series forms parallel ranges (Suma-Khada, Ta-tsing-shan, Khara-narin-ula and others) which if not homologous with the great Khingan, are at any rate analogous to it and constitute the south-eastern scarp-edge of the whole plateau, sloping gradually north-westward to the Gobi depression. The inner series is made up of denuded fold-chains partly within the line of the Great Wall (in the neighbourhood of Kalgan) and forms the frontier-zone between Mongolia and the alluvial plain of north China. Between these two series is an intermediate zone of lower elevation and this is economically the vital part of "Inner Mongolia." Of a different character, however, is the more or less level Ordos plateau contained within the immense Hwang Ho loop. It has the appearance of an ancient stable block; its surface of sandy or loamy soil is in parts not unsuited for agriculture, especially with irrigation. The surface of Inner Mongolia is marked by numerous small brackish or salt lakes.

Differences in Climate and Vegetation.—The differences here noted between the three major regions of the Mongolian tableland are further accentuated on climatic and vegetational grounds. The plateau as a whole is naturally characterized by dryness and great seasonal range of temperature, *i.e.*, "continentality." During the winter half-year the Asiatic high pressure system is centred over the northern edge of the plateau, while pressure is lowest in June, July, August. The whole area is one of outflowing winter and inflowing summer winds. The latter come from two main directions: west or north-west affecting Outer Mongolia, and south-east (monsoonal) affecting Inner Mongolia. The difference in mean temperature between the north-west and south-east of the plateau is considerable, amounting to about 20° F on the average of the year. But the contrast is much greater in winter than in summer when the temperature is relatively uniform over the whole area. The Altai-Sayan mountain-complex in the north-west partakes essentially of the Siberian climatic régime; the winter cold and annual range of temperature are here at their maximum. The total annual rainfall (including heavy snowfall) averages 10–20 in., but coming as it does from the west is not of the "monsoonal" type. Winds are probably not so strong or frequent as in Gobi, for Urga (on the edge of the region) is reported to have calms on 40% of the days in the year. It has a mean January temperature of 15° F and a mean July temperature of 64° (tempered by altitude) showing an abnormal range. The average annual rainfall here is between 9 and 10 inches, which is less than that of the north-west as a whole. The Gobi represents the classic example of a region with an extreme or continental climate. Winds blow unimpeded almost all the year round, mainly from the north-west. The rainfall is almost negligible in the real Gobi; the dryness is due to the fact that rain-bearing southerly winds have deposited their moisture on the successive high marginal ridges which border the plateau on the south-east.

On the other hand the Pacific influence is reflected in the climate of Inner Mongolia which more than any other part of the plateau is definitely affected by the monsoonal régime of summer. In the winter half-year winds are predominantly from the north-west bringing extreme cold; while dust-storms arising in Gobi are a common feature. The summer monsoon from the south-east brings the rains, averaging from 10 to 15 inches annually along the plateau edge, beyond which they rapidly die away.

The vegetational conditions correspond closely to these contrasts of climate. The north-west has Siberian affinities. On both sides of the Sayan are dense forests of larch, cedar, pine and deciduous woods characteristic of the Siberian flora. These decrease to their southern limits on the northern slopes (only) of the Khangai and Tannu-ola. With this exception the surface of this lofty mountain-complex is marked by prairie-land, furnishing excellent pasture in the wide basin-like valleys or plains. The rivers of the Urianghai basin are abundantly stocked with fish and the meadow-land of the floor of the basin affords very rich pasture; the area also contains valuable mineral deposits, and is capable of supporting a larger population. From the Tannu-ola southwards, the treeless zone extends to the unforested Altai; the gravel surface generally yields dry prairie-land.

The Gobi division, as a whole, must be regarded rather as a poor steppe-land than desert proper. On its northern limits around the Kerulen river, high mountains bearing larch and spruce woods alternate with river valleys which afford areas of good pasture. Steppes succeed southward, merging into the Shamo or Gobi proper which is barren of vegetation save in spring and early summer. Physiographically, climatically and vegetationally Gobi is a very real divide between Inner and Outer Mongolia, whose

affinities in a physical sense are with China proper and Siberia respectively.

The description of Inner Mongolia as a "land of high grasses" implies its pastoral wealth, but much of it has also potential agricultural value. This is particularly true of the fertile zone from the Ala-shan along the alluvial course of the Hwang Ho to the north-east of Kalgan, *i.e.*, along the intermediate belt between the plateau edge and the series of ridges within the Great Wall. The Ordos is a region of stunted steppe vegetation on the whole, but the In-shan series of mountain ridges (*i.e.*, the plateau edge) contains well-watered and sheltered valleys yielding an abundant vegetation.

POLITICAL GEOGRAPHY

From very early times the Mongolian Plateau was inhabited by nomadic groups but the term Mongol is comparatively late. It is apparently derived from *mong* (brave men), the earliest mention of which is in the annals of the Chinese T'ang dynasty (618–907) where reference is made to the *mong-ku* invaders. The original homeland of the historic Mongols was the area between the Onon and Kerulen rivers south-east of Lake Baikal whence they extended their conquests (*see* MONGOLS) until their power reached its zenith in the vast empire of Kublai Khan (13th century). The break-up of their empire and the fall of this dynasty (the Yüan) in China were followed by disintegration in Mongolia, where independent communities under separate chiefs came into existence. Soon afterwards the Manchu dynasty was established in China and, following the policy adopted by the Han and T'ang dynasties, set about the task of controlling the critical steppelands of the interior. The Mongol tribes whose lands were adjacent to the northern frontier of China early submitted but the more remote Khalka and Kalmuk tribes beyond the Gobi Desert were not brought under control until the reign of K'ang-hsi (1661–1721) or even later. Hence the present distinction between Inner and Outer Mongolia was foreshadowed at this period. In 1689, at the Congress of Dolonor, Mongolia accepted Manchu rule and for more than two centuries the entire area was a dependency of the Manchu Empire. But immediately after the fall of the Manchus in the Revolution of 1911, the northern Mongol princes expelled the Chinese officials at Urga and declared their independence under the rule of the Living Buddha. The political distinction between Outer and Inner Mongolia then finally emerged and corresponds essentially to the natural divisions distinguished on physical grounds. The arid, almost empty wastes of the central Gobi separate the two relatively fertile marginal areas to the north and south which form the cores of Outer and Inner Mongolia respectively, the one orientated towards Siberia, the other towards China. In outlook, in political status, the composition of their populations and in the trend of their economic developments, these two divisions are now quite distinct and the term "Mongolia" used in a political or even in an ethnic sense has now little significance save in relation to the northern republic.

Inner Mongolia comprises a broad belt adjacent to the northern border of China from south Manchuria on the east to Kansu on the west. Its northern boundary against Outer Mongolia runs through the heart of the desert to the great Khingan. Its eastern boundary with Manchuria extends beyond the Khingan and runs south-eastwards almost to the coast of the Gulf of Liao-tung to include the broken eastern extension of the plateau. The boundary is parallel to the coast for a considerable distance, leaving to Manchuria only a narrow sill traversed by the main route from Peking to Mukden. Opposite Shan-hai-kwan ("the Gate between mountain and sea") it turns west to follow the line of the Great Wall along the scarplands north-west of Peking. Much of this eastern portion of Inner Mongolia, known as Jehol, is drained towards and geographically related to Manchuria. From Kalgan the southern boundary follows the outermost scarp along the Great Wall and traverses the Ordos plateau, crossing both arms of the gigantic loop of the Hwang Ho. Finally it runs north-west into the desert, forming in this western section the northern border of the Kansu corridor.

The outstanding features of Inner Mongolia are the progressive development of Chinese influence and the replacement of nomadism by agriculture and pastoral farming. In the seventeenth century there were few Chinese outside the Great Wall, nor did the early Manchu Emperors encourage emigration. But the Dynasty in its later years, inspired by fear of Japanese pressure from the east and Russian pressure from the north, adopted the Chinese policy of colonization and of direct control of the Mongol tribal organizations through Chinese officials. The establishment of the Republic was followed by a complete political re-organization of Inner Mongolia, bringing it into integral relationship with China proper. With the addition of the portions of the provinces of Chihli and Shansi which lay to the north of the Great Wall there were formed in 1914 the three administrative areas of Jehol, Chahar and Suiyüan (with capital cities at Jehol, Kalgan and Kweihwating respectively) while the semi-desert region of the extreme west was constituted the military district of Sitao and placed under the control of Kansu. Shortly afterwards the Revolution which terminated the Tsarist régime destroyed Russian influence in the south and allowed the policy of active Chinese assimilation to proceed unchecked. The process has been carried a stage further by the introduction of the *hsien* (county) system and the usual machinery of provincial administration, and the complete incorporation of at any rate Chahar and Suiyüan as provinces of China seems only a question of time. They are included in the northern group, which comprises Hopeh (formerly Chihli) Shansi and Kansu, at present under the control of Yen Hsi-Shan, the Governor of Shansi. (*See* under CHINA: *Administration.*) Jehol is at present in a slightly different category, since it is within the Manchurian sphere. In all essential respects, however, it is becoming as Chinese as Chahar and Suiyüan and this trinity is often known as the "Three North Western Provinces" in contra-distinction to the "Three Eastern Provinces" of Manchuria.

Inner Mongolia may now be regarded as virtually a large extension of China to the north-west. It is of great importance both as an outlet for colonization and a new field for agricultural and pastoral development. The influx of Chinese has naturally been greatest in those districts offering the best prospects for tillage. These include (a) the valleys and terraces lying within the inner belt of scarps in Jehol and Chahar, especially along the route of the Peking-Kalgan-Suiyüan Railway, (b) the intermediate belt between these and the outer scarps which form the plateau edge and (c) the alluvial lands round the northern bow of the Hwang Ho which embraces in the north of Ordos a valuable agricultural plain known as the Ho Tou. In these districts the population is now overwhelmingly Chinese and nomadism has practically disappeared. The agricultural "front" is approximately represented by the plateau edge extending from the In-shan chains towards the great Khingan, beyond which line the scanty grasslands, merging into desert on the northern frontier, still support scattered groups of pastoral Mongols. The central portion of the Ordos plateau, enclosed within the great bend of the Yellow River, represents an "inlier" of this poor steppeland type and is also a pastoral area inhabited by Mongol nomads or semi-nomads, but is now encircled by agricultural lands which are still expanding. Recent estimates place the total population of Inner Mongolia at about one and a half millions, of whom the great majority are Chinese. There is but little intermixture, for where the Chinese farmer arrives with his spade the Mongol withdraws with his herd. Only in very exceptional cases does the Mongol adopt agriculture. Two entirely different economic systems are in conflict and the herder, no longer supported by military force, must give way to the peasant. But much of Inner Mongolia is better adapted for animal rearing than for any other economic use and the Mongols, with improved methods, may yet find their place in the new régime. From time immemorial China has been a great market for Mongolian ponies, and the demand has in recent years been raised by military needs and the increase of horse-racing in the big cities, which has led some of the Mongol herd-owners to take an interest in systematic breeding. With the support of the chiefs an important experiment in dairy-farm-

ing on modern lines but adapted to Mongol methods has been made in Chahar with very considerable success, and Kalgan, Peking and Tientsin are increasingly important as markets for pastoral products of all kinds. The agriculture carried on by the new Chinese colonists (who are so far mainly Mohammedans), or by the large class of seasonal workers from Shansi, is naturally of the type characteristic of North China—oats, wheat, buckwheat, millet, rapeseed, kaoliang, sesamum and beans being the principal crops. The low rainfall makes tillage without irrigation somewhat precarious, but in some districts irrigation is possible on quite a large scale, notably in the Wuyüan district of Suiyüan. Here around the north-western angle of the great Yellow River bend, an extensive system of irrigation canals between the present course and a deserted channel to the north has converted over 150,000 acres of arid land into productive fields. Elsewhere irrigation must mainly depend on wells and storage of water in the mountains. In the non-irrigated lands, dependent upon rainfall, mixed farming, combining stock-raising with the cultivation of the soil, is being strongly urged upon the Chinese settlers, whose natural inclination is to rely exclusively on their crops. It is noteworthy that afforestation is being actively promoted by the authorities in Chahar and Suiyüan. In the aggregate there is a considerable number of small-scale industries, mainly based upon pastoral products. They include the manufacture of rough woollen cloths and rugs, the preparation of felt, furs and leather, soap factories in which the acrid Mongolian "butter" is used, and paper-making from hemp ropes. Kalgan is the chief emporium of the skin and fur trade and the main collecting and distributing centre for Inner Mongolia. (*See* KALGAN.) Peking (Peiping) and Tientsin are the two chief external markets but there is a growing Japanese demand for the pastoral products of this region, more especially cattle.

Transport in Inner Mongolia is still mainly dependent upon camels, horses and ox-carts, using the ancient caravan tracks, but motor and rail traffic is steadily increasing. A feature of recent years has been the construction of motor roads by soldier colonists on the model adopted in Shansi, whose governor (Yen Hsi-Shan) is in charge of Inner Mongolia. Motor services now operate between Kalgan and Urga (Outer Mongolia), Kalgan-Dolonor (200 miles), Kalgan-Pingtichuan (170 miles), Pingtichuan-Pangkiang (250 miles), Paotowchen-Ninghsia in Kansu (400 miles) and another is planned from Kalgan to Jehol. The construction of the Peking-Kalgan-Suiyüan Railway has already been of great value in the development of Inner Mongolia and is noteworthy as having been entirely constructed and maintained by Chinese capital and engineers. It follows the ancient caravan route up the historic Nankow pass and taps not only some of the richest agricultural and pastoral lands but also a mineral district of considerable value. In recent years it has been pushed slowly westwards as far as Paotowchen, the present terminus, on the northern bend of the Hwang Ho. Another important railway is now projected to link Peking with Jehol, the most easterly of the Inner Mongolian "provinces." It is to be in three sections: Peking-Jehol (130 miles), Jehol-Chihfêng (140) and Chihfêng-Tungliao (330), there to connect with the new Chinese railway system in western Manchuria. It should be noticed that the development of Inner Mongolia must inevitably increase the importance of Peking, its natural point of intersection with north China.

Outer Mongolia or the Mongol People's Republic.—The proclamation of the independence of Outer Mongolia and the expulsion of Chinese officials by the Mongol princes assembled at Urga after the fall of the Manchu Dynasty in 1911 have been already noticed. Since then the country has passed through many political vicissitudes and has been the scene of more than one revolution. Its present status, so far as it can be clearly defined, was determined by the events of 1924. In that year the death occurred of the last Khutukhtu or "Living Buddha," the theocratic ruler of the country, who claimed to be the incarnation of a disciple of Buddha. It was almost immediately followed by a revolution fostered by agents of the Soviet Russian power, which was then actively pursuing the policy of recovering control of the central and eastern Asiatic lands formerly belonging to or within the sphere of influence of the Tsarist Empire, but which as a result of the Russian Revolution had been lost for the time being. The Mongol Revolution of 1924 established the Mongol People's Republic and in November of that year a constitution was promulgated in the name of the First Great *Huruldan* (People's Assembly), the object of which was "to inaugurate in the country a republican régime, without a President at the head of the State, all supreme power to be vested in the Great Assembly of the People and in the Government elected by the latter."

The following were declared to be some of the chief objectives of the new régime:

1. "The abolition of the remains of the feudal theocratic régime and the strengthening of the foundations of the new republican order on the basis of a complete democratization of the administration of the State."

2. "All the lands and mineral wealth, forests and waters and their resources . . . (to be) the property of all the people."

3. "The unified economic policy of the country . . . to be concentrated in the hand of the Government and a State monopoly of foreign trade to be introduced."

4. "The labouring people . . . to be armed by means of the creation of the Mongol People's Revolutionary Army and through the military training of all labouring youth."

5. The separation of Church and State and the establishment of the principle that "religion is the private concern of every citizen."

It was decreed that the Great Huruldan or People's Assembly should be composed of the representatives of the "aimaks" (*i.e.,* the old tribal units) and towns, as well as of the units of the army; and that there should be local huruldans corresponding to the "aimaks," "hoshuns," and other territorial divisions, thus preserving certain features of the old social organization for purposes of local government.

In its general character this constitution follows the Soviet model, and the Revolution of 1924 is generally interpreted as marking the absorption of Outer Mongolia into the Russian Federation of Soviet Republics. But technically China has not abandoned her Suzerainty which was even admitted by Russia in the year following the establishment of the Mongol Republic. In a statement on Russian foreign policy in 1925 Commissar Chicherin said: "The Soviet Government recognizes Mongolia as part of the whole Republic of China, enjoying, however, autonomy so far-reaching as to preclude Chinese interference with the internal affairs. . . . It ought to be noted that after several crises the internal situation in Mongolia has settled down and been consolidated on a basis similar to the Soviet system." It would be hazardous to say that Outer Mongolia is being absorbed by "Russia" in the same sense that Inner Mongolia is being absorbed by China, for the attitude of the Mongol people and the ultimate political orientation of Eastern Siberia are both uncertain. All that can safely be asserted is that Outer Mongolia has broken away from China and that her economic relations and political affinities are now with the Soviet Federation.

The Mongol People's Republic is bounded on the north-west by the high crests which form the buttress ranges of the plateau, and extend from the Altai through the Sayan mountains—essentially a natural frontier. The boundary then passes well to the south of Lake Baikal, cutting across the Selenga-Orkhon and Kerulen river-systems which orientate this north-eastern section of Mongolia towards Trans-Baikalia. Its short eastern boundary, abutting on Manchuria, lies to the west of the great Khingan. The southern boundary with Inner Mongolia follows the centre of the Gobi. The total area of the state is probably about 1,000,000 square miles, but the productive regions are concentrated in the north near the Siberian frontier, where the grassland becomes richer and grades into forest on the mountain slopes. In contrast to Inner Mongolia the population is essentially Mongol, comprising two principal tribal groups: the Kalmuks in the west, the Sharra and Khalkhas in the east. These are the purest and most typical of the Mongols, but the Buriat tribes of Trans-Baikalia,

although mixed with other racial elements, are closely related to them and form another point of contact with the Russian sphere. The differences between the Khalkha, Kalmuk and Buriat dialects are comparatively small (*see* Whymant, *A Mongolian Grammar* [1926]). There is hardly any Mongol literature, partly because the written language is very different from the colloquial, and partly because the liturgical lamaist books are written in Tibetan. Lama-Buddhism is everywhere the popular religion. It gradually replaced Shamanism from the time when Kublai Khan adopted Buddhism and instituted the Dalai Lama, the Pope of the Tibetan and Mongolian Buddhists; and its spread was encouraged by the Manchu Emperors as a convenient instrument for taming the wild Mongol nature. Buddhism has indeed appreciably changed the habits and outlook of the Mongols as a whole, converting a race of virile warriors into inoffensive and generally indolent herdsmen. Their potential military strength was further sapped by the Manchu policy of weakening the original tribal organization and bringing it under the control of their officials. It remains to be seen whether the abolition of the theocracy, the revival of military training and association with the Soviet régime may again alter the bias of the national character. The Mongols were formerly the classical example of pure nomads, but, as part of the general change in their mode of life induced by the Manchu policy of restricting tribal organizations to fixed areas, they have in large part settled down, although seasonal movement between winter and summer pastures by individual families is still common. The herds remain the chief source of wealth. According to the latest available information (1928) there are in the Republic approximately 1,340,000 horses, 270,000 camels, 1,500,000 oxen and 10,600,000 sheep. It is also the avowed policy of the Mongolian government to foster the development of local industries by a protective tariff. Trade relations are now almost entirely with the Soviet Federation, and Outer Mongolia only communicates with the outer World through carefully regulated Soviet channels. Not only has the immigration of Chinese been forbidden but the formerly extensive trade between Kalgan and Urga has greatly dwindled. Urga, the chief emporium of the country, now trades chiefly with Kiakhta, on the frontier 170 miles to the north and the terminus of a branch-line from the Trans-Siberian Railway. The trade with Russia is reported to have increased from 7,115,000 roubles in 1925 to 12,186,000 roubles in 1926. The chief exports are wool, skins, furs and horns together with salt and some gold. In addition to many gold mines, of which few are at present worked, there are deposits of copper, tin, iron and silver, but no general statement as to the mineral wealth of the country can be made. Within the Republic communications are mainly restricted to the caravan tracks but contact with Siberia is being developed in various ways. In collaboration with Soviet Russia new telegraph lines have been planned and in part constructed, and steamer services inaugurated on the Selenga and Orkhon rivers. A railway agreement is reported to have been made in September 1926 between the Union of Socialist Soviet Republics and the Mongol People's Republic, by which the former has undertaken to build a railway between Urga and Chita; one-fourth of the constructional expenses is to be borne by the Government of Outer Mongolia and the rest by the Government of the U.S.S.R. which is to have control of the line and liberty to exploit the resources of a belt 100 versts in width on each side of the railway. According to the latest estimates (October 1928) the population of the Mongol Republic contains 579,000 Mongols, 90,000 Russians and 7,000 Chinese.

ANTHROPOLOGY

The terms "Mongol" and "Mongolian" have been very much abused owing to the fame of Jenghiz and Kubla Khan, and are, indeed, often applied to all the inhabitants of the Far East. Mongol should, however, be limited to a purely linguistic and national sense and should include only the speakers of Mongol languages, who are connected to a certain extent culturally, and often only distinguished from their cousins the Turks, by difference of language. Physically, although probably to a large extent Armenoid, they have come into contact with a variety of other stocks which have considerably modified the original type, which varies from district to district. Within historical times the Mongols have wandered far and wide over an area which has always been thinly populated. On the other hand, among nomads over a large area there is apt to be less divergence of type than in a settled population of relatively greater density. These two different aspects will serve to explain their remarkable homogeneity which appears in spite of local differences. The racial history of the Mongols as an entity begins with Jenghiz Khan, whose father was the ruler of only 40,000 tents. Jenghiz was born about 1165 "with a piece of clotted blood in his hand." His horoscope foretold a bloody career, and the prophet in this case did not lie. He succeeded in binding the Mongols into a loose political organization, which in its original form did not survive his death, but the fruits of his military genius were sufficient to carry the Mongol horsemen over most of Asia and as far into Europe as the walls of Vienna. Under Kubla Khan the Mongols conquered China and held it for a brief period. Their racial history has, however, always been of varied fortunes; they have advanced westwards and southwards and they have retired again. Under the Mings, Inner Mongolia, one of the most typical Mongol countries, was cultivated by the Chinese, and to-day the Chinese are once more invading with the plough this virgin prairie land, "the country of the long grass." (*See* MONGOLS.)

Racially, these slow movements are probably more important than the greater cataclysmic invasions of the Mongol armies. The Chinese, being sedentary agriculturists, definitely establish their racial type wherever they settle. The nomad Mongol, with his perpetual movement, makes tremendous incursions, but owing probably to the smallness of his numbers in relation to the area occupied does not permanently establish his type where there is racial competition from people who settle a smaller area with a denser population.

The Mongols may be conveniently divided into three groups: the Western Mongols or Eleuts (*q.v.*), who are called Kalmucks by their neighbours; the Central Mongols or Buriats (*q.v.*); and the Eastern or "true" Mongols, the descendants of Jenghiz's soldiers, at present inhabiting Gobi and Inner Mongolia.

Social Organization.—The Mongol social organization is somewhat complicated owing to its dual nature, partly ecclesiastical, partly military (among the Muslim Mongols the ecclesiastical organization does not, of course, exist and their social system is similar to that of the Turks). The lay population is divided into two classes, the serfs and the nobles, to certain families of whom the hereditary princes (Jassak) belong. The clergy include the higher clergy—that is, the living Buddhas who, except in one case, which is hereditary, are chosen at birth as "reincarnations," and the lamas, it being necessary for the religious before taking the vows to obtain the permission of his overlord,—and the ecclesiastical serfs, who are presented by their chiefs to monasteries. The clergy are celibate, but the laity are polygamous, to a greater

or lesser extent, and at least in Inner Mongolia to-day about two males out of three take vows. The laity are organized for the most part on a military basis, the religious being excused service.

The unit of organization is the *bak* or group, a small conglomeration of tents on the steppe, governed by an elected elder. A number of groups form a banner under its hereditary prince, usually the eldest son of the last prince, although certain princes, known as "seal-less" princes, and some nobles have no banner. The adult males are also organized into troops of horsemen and the latter into regiments. The prince has complete control over the persons of his subjects, although to a certain extent the old steppe law has been modified by the Russians and Chinese in their respective territories. Its first and foremost principle is military; disobedience to the khan or his subordinates is immediately punished by death. Otherwise crimes are punished by a payment, usually in kind, cattle, sheep or camels, to the sufferer or his group. The banners are grouped together into a confederacy, which forms part of the heritage of a single princely house, and was formerly ruled by the ancestor of all the princes who now hold the more or less independent banners which compose it. The Manchus somewhat modified this system by introducing leagues with elected princes, managing to secure the election of their nominee, most of the confederacies more or less corresponding to existing confederacies.

The mode of life is intimately associated with geographical conditions. The food quest is limited practically entirely to the products of their herds; chiefly of sheep and ponies. They have two types of houses. The travelling tent is a simple ridge pole tent, covered with dark felt. The more permanent tent or *yurt* consists of a lattice framework standing upright to about a man's height, on top of which is a sloping frame which forms the roof; a space is left open at the top to allow the smoke to escape, and the top is supported by a central pole. The whole frame, roof and sides, is covered by thick felts and anchored by ropes thrown over the whole structure and tied at the bottom to large stones. The yurt can be dismantled in about half an hour. The Mongol villages consist of a small collection of tents, usually situated in a subsidiary valley, to be near wells in the main valley, but protected from the great winds of the plains. The village usually possesses some sort of corral to protect the weaker animals from wolves. Another important feature is the great pyramid of dried dung which in this treeless country supplies the place of wood for burning. The flocks supply milk, mutton, wool, skins, and as a by-product of the milk a simple fermented liquor and a distilled and fiery spirit, usually called *arrack,* a word which, however, is applied in Turkish to grape brandy and practically means a spirituous liquor. Huge shaggy and very fierce dogs effectually keep off stray marauders and wolves and act as scavengers, eating up all the bodies of dead animals. The sheep are kept near the village both because they are looked after by the children and because their droppings are so valuable. The pony herds are kept farther away. The Mongols almost live in the saddle, riding upright and shifting the weight from one leg to the other. The ponies in immediate use are kept tied up near the village, one especially fast and carefully trained beast being always at hand to act as the "lassoo" pony. When a beast is wanted from the herd a rider mounted on this pony takes a rod with a noose at the end, picks out the beast he wants to take, rides up and drops the noose over its head, tightens the noose and plays it as a fisherman, riding it round in circles till it gives in. The lassoo pony must be sufficiently fast to keep a neck ahead of any pony to be captured. The horsemanship of the Mongols can be best judged by the ride of one of their best men, who did the 1,500 miles from Ulliassetai to Peking in eight days, changing ponies at each of the posting places, 15m. or so apart, which used to be kept up along the imperial routes. Any man on a pony picked out of the herd will think nothing of doing a hundred miles in one day. Along the trade routes camels are used, usually as pack animals, but sometimes for draught; elsewhere, however, the pony is the indispensable associate of the Mongols. They do a good deal of trade, especially in horseflesh, and by these means supply additions, such as grain and sugar and tea to the products of their herds. In the *taiga* region, where game is more easily approached, many of the men are hunters. The craft of silver work is highly developed. Every married woman wears an elaborate head-dress of silver and stones, worked by the Mongols themselves. Although modern rifles are being introduced into Mongolia as a result of the recent wars, their true weapon, which is still used ceremonially, is a bow made of horn backed by sinew. It is overstrung, *i.e.,* in making the bow it is so moulded that the belly of the bow when unstrung is directed backwards, instead of forwards as it is when the bow is strung. Unlike so many other peoples in a similar stage of culture, the Mongols do not put all their amusements and recreation into certain feasts, but are always ready to try their horses with any available person, and take immense pleasure both in the casual race, whenever opportunity offers, and the more organized races, such as those which take place at Urga, where, in order to test the speed of the horses, only small children are allowed to ride.

Religion.—Apart from the immigrant Chinese, two types of religion are prevalent in this region, Islam and Buddhism. The followers of the former religion include both Mongols and Turks. They are, as in China, always a turbulent element in the population. They are often somewhat fanatical, and on the whole fairly strict, even to the extent of not smoking cigarettes, a practice which has become so general over the Muslim world. Observations made along the border land a few years ago by Buxton suggest that the Muslims are spreading to a certain extent at the expense of the Buddhists, probably owing, among other things, to the low birth-rate of the latter, but there do not appear to be any definite statistics. This increase among the Muslims is especially noticeable in the new towns which are springing up on the site of ancient cities which have fallen into ruin in the last few hundred years (since the great invasions of the Mongols in the 13th century). In a land where learning is not a conspicuous feature, some of these Muslims have a slight knowledge of Arabic, and, probably associated with their religion, a somewhat wider knowledge of the world than their neighbours. Apart from their turbulence, it would not appear that religious differences were associated with any great difference of cultures, and, indeed, except for the fact that the Mongols on the whole avoid towns, the two cultures have very many points in common. Buddhism in Mongolia is similar to that in Tibet (*q.v.*) and presents no special local features. There are, however, certain local differences of interest. The lamaseries form the only permanent habitations in this land of nomads, but the lamas are not confined to their convents, and in practice large numbers of them are wanderers. The older shamanistic religion exists side by side with the higher and more orthodox faith. Among a pastoral people the Buddhist objection to the destruction of life cannot exist, and the slaughter of animals, and even their actual sacrifice, an idea entirely repugnant to Buddhist ideals, forms an important part of many Mongol ceremonies, including that of marriage. Over much of Mongolia there are ancient *obos* or stone altars, placed especially on conspicuous, rocky outcrops. Ceremonies take place at these *obos* at intervals. In the remoter districts shamanistic rites still take place, usually towards nightfall. A fire is lit outside the tent and animals are sacrificed. The chief performer, man or woman, begins by reciting traditional spells and gradually works into a hysterical condition, during which he may see visions, and finally falls unconscious on the ground. In contrast to the regular Buddhist priests, however, except in Uriankhai there do not seem to be any regular shamans, their place being taken by anyone who is of such a mental condition as to be able to perform the ceremony; this matter is, however, not certain.

The general features of the mode of life of the inhabitants of Mongolia contrast very strongly with that of their most intimate neighbours the Chinese. They entirely lack any real form of cohesion, and though the Mongol princes have at times been able to combine and conquer immense territories, the death of the khan has usually been the signal for the break-up of his dynasty. To-day their life can be seen probably most typically in the region south of Gobi, a region which at various times has been given over to Chinese agriculturists, in the Ming dynasty, for instance. The effect of the building of the Great Wall of China was to turn the tide of the nomad westwards. The Chinese are pushing many miles

beyond the wall, into a country which is suited naturally to pastoral nomadism, and though the nomad cannot exist when the agriculturist has passed by, any slight change in environment which compels the agriculturalist to retire results in the land returning once more to pasture.

EXPLORATIONS

The existence of an Asiatic centre of origin or homeland where ancestral types of mammalian life developed millions of years ago and spread westward to Europe and eastward to America had long been a matter of purely palaeontological theory. In 1900 Prof. Henry Fairfield Osborn, president of the American Museum of Natural History, New York, summarized his conviction of the truth of the theory and plotted on a map the regions in which he believed the great orders of mammals had originated. (*Science*, April 13, 1900, p. 567.) His belief, however, was entirely based upon inductive reasoning, for the fossil history of Asia was unknown.

Central Asian Expeditions.—This prophecy was responsible for the original conception of the central Asiatic expeditions. After ten years of zoological work in various parts of Asia, plans took shape to test the theory by scientific exploration of the little known central Asian plateau. The main problem was to discover the geologic and palaeontologic history of central Asia; to find whether or not it had been the nursery of many of the dominant groups of animals, including the human race; and to reconstruct its past climate, vegetation and general physical conditions, particularly in relation to the evolution of man. It was necessary that a group of specialists be taken into central Asia *together* in order that the knowledge of each man might supplement that of his colleagues. Probably no archaeologist could have dated the culture and unravelled the story of the dune-dwellers, a prehistoric race which was discovered, without the assistance of other scientists. This was indeed the first expedition of such magnitude to employ these methods. The fossil history of central Asia was completely unknown. The British had made some discoveries of importance in India. In China fossil teeth and bones had long been sold for medicine and a few had been studied by English and German scientists. Some interesting and important finds had been made in Java, Persia and Asiatic Russia. But these all came from the edge of the interior continent. Literally, the only fossils known from the central Asian plateau were a few "rhinoceros" teeth discovered by the Russian explorer, Obruchev, in 1894–96. Mongolia is isolated in the heart of a continent; and there is not a single mile of railway in the country, which is nearly half as large as western Europe. The climate is extremely severe; the temperature drops to −40° to −50° and the plateau is swept by bitter winds from the Arctic. Effective palaeontological work can be conducted only from the beginning of April to October. In the Gobi desert, which occupies a large part of Mongolia, food and water are scarce and the region is so inhospitable that there are but few inhabitants.

The physical difficulties could only be overcome by some means of rapid transportation and that transportation the motor car successfully supplied. The automobiles could run into the desert, as soon as the heavy snows had disappeared, at the rate of 100 m. a day, penetrate to the farthest reaches of Mongolia and return when cold made work impossible. Camels, which other explorers had used, average 10 m. daily. Thus, approximately ten years' work could be finished in one season. A supporting caravan of camels, with food and petrol (gasolene), must go out months before the motor parties. The expedition of 1925 had 125 camels carrying 4,000 gal. of petrol, 100 of oil, 3 tons of flour, 1½ tons of rice and other food in proportion. The caravan was to leave petrol and food at two depots and wait at a well 800 m. out in the desert.

The 1925 expedition of 40 men comprised the following branches of science: palaeontology, geology, palaeobotany, archaeology, topography, zoology and photography. The foreign staff included 12 Americans and 2 British; in the native staff there were 26 Chinese and Mongols, some being highly trained assistants. With so many branches of science represented it was improbable that all the men could find work in the same place at the same time. Therefore, the expedition was divided into four units, each with a car complete with its own driver, interpreter, cook and camp gear; any unit could leave the base camp and maintain itself independently for several weeks if necessary. As a matter of fact the expedition was almost continually divided except on long marches to new localities; frequently there were four camps from 20 m. to 100 m. apart.

General Survey.—It became evident that the first season must be devoted to a general survey of several thousand miles of country to locate and appraise its value for the especial purposes of the expedition without attempting exhaustive work in any of them. The next year could then be one of intensive study, the amount of time to be devoted to each locality be carefully planned in advance, and the staff adjusted accordingly. Since the main object of the expedition was to test the theory of central Asia as the chief theatre of mammalian evolution and distribution, palaeontology was most important during 1922–23.

Contrary to expectations, rich fossil deposits were discovered immediately. Four days after starting in 1922 it was found that the main trail between Kalgan, China and Urga, the capital of Mongolia, which had been traversed by several geologists, runs directly through three rich fossil beds—one Oligocene and one Eocene, of the age of mammals, and one Cretaceous, of the age of reptiles. The palaeontological work of the expedition, which was carried on under the direction of Walter Granger, "revealed the high central Asiatic plateau as the home of most of the terrestrial dinosaurian reptiles of Upper Jurassic and of Cretaceous time. In brief, these discoveries establish Mongolia as a chief center of northern terrestrial life-history from the close of the Jurassic time onwards to the very close of Pleistocene time" (Osborn).

Since the middle of the age of reptiles, Mongolia has been continuously a high, dry continent. As a result, fossils "revealed especially the hitherto unknown high continental life of Cretaceous and Tertiary times" and showed that Gobia, as Grabau has named this ancient central Asian continent, was then sparsely forested, with limited rain supply and luxuriant with life, although it is now one of the most arid and inhospitable regions of the world. It was "extremely favourable to the evolution of reptiles, mammals, insects and plants hitherto known only along the Cretaceous shorelines of Europe and the Cretaceous sea-borders of the centre of America" (Osborn).

Dinosaur Eggs.—Among the several thousand fossil specimens obtained it is difficult to select those of first importance scientifically, but in popular interest the dinosaur eggs stand foremost. These were discovered among dinosaur remains in a rich deposit almost in the centre of Mongolia near a well known to the Mongols as *Shabarakh Ussu*, the "Place of the Muddy Waters." The beds consist of fine red sandstone of Lower Cretaceous age and are extremely rich in skulls and skeletons of a hitherto unknown dinosaur, *Protoceratops andrewsi*. Bits of shell were discovered in 1922 but were not recognized as dinosaurian. The following year, on July 13, George Olsen found the first complete eggs. Three had broken out of a small sandstone ledge and lay exposed. Other shell fragments were partially embedded in the rock; just under the shelf were the projecting ends of two more eggs. Subsequently the block was found to contain 13 eggs in two layers lying with the ends pointing toward the centre, exactly as they had been left by the dinosaur when she covered them with sand for the last time millions of years ago. The skeleton of a small dinosaur was found, lying 4 in. above the eggs in the loose sediment on top of the rock. The specimen represented a toothless species, *Oviraptor philoceratops*. It is possible that this little dinosaur existed by feeding on the eggs of its relatives and was about to rob the nest when it was buried by a sudden sandstorm. The eggs first discovered are 8 in. long by 7 in. around. They are rather more elongate and flattened than those of modern

reptiles and differ greatly in shape from the eggs of any known bird, living or fossil. The dry country and the loose, extremely fine, sand probably explain how such delicate objects as eggs were so beautifully preserved. After they had been deposited in a shallow "nest" scooped out of the sand the dinosaur covered them with a thin layer of sediment and left them to be hatched by the warmth of the sun. In a sudden wind storm, many feet of sand might have been heaped upon the eggs. Air and sun were thus cut off and incubation abruptly ceased. The weight of sediment eventually cracked the shells and the liquid contents ran out. Simultaneously the fine sand sifted into the interior forming the solid cores which are present in all the specimens. The loose sediment of the entire region was eventually consolidated into red-sandstone, the matrix in which all the eggs are enclosed. Two of those from the original discovery were somewhat broken exposing the delicate skeletons of embryonic dinosaurs. It is probable that other eggs contain the bones of unhatched young, for there were found several skulls of baby dinosaurs which evidently had been out of the egg only a few days before death.

In 1923 the expedition discovered about 25 eggs, whole or in parts, and, in 1925, 40 more. That year produced by far the largest and finest eggs, as well as the smallest, representing several species and genera. One type, probably laid by a small carnivorous dinosaur, is not more than 5 in. long, is very elongate and has an extremely thin, smooth shell.

There were also bits of egg-shell probably representing one of the larger iguanodont, duck-billed dinosaurs from another region in Mongolia which awaits further exploration. Only in these two localities of the world have dinosaur eggs been discovered up to 1928, with the possible exception of a few somewhat doubtful shell fragments from Rognac, southern France. Shabarakh Ussu also yielded 75 skulls and 14 dinosaur skeletons, probably the finest preserved material of the sort. One superb series of *Protoceratops* skulls represent almost every stage of growth from the newly hatched young up to very old individuals.

The Baluchitherium.—Another discovery, second only in popular interest to the dinosaur eggs, was the skull and parts of the skeleton of the gigantic aberrant rhinoceros *Baluchitherium*, the largest land mammal known to have existed. First information of this extraordinary beast was given by C. Forster Cooper of Cambridge university, who found a neck vertebra and foot bones in 1911 in Baluchistan. But it was not until the discovery in Mongolia of an almost complete skull in 1922 that the real characteristics of the animal became known. In 1925 were found the four legs and feet of another individual that evidently had been trapped in quicksand and buried alive. It is estimated that the *Baluchitherium* stood 13 ft. high at the shoulders, that it was about 24 ft. long and that with its prehensile upper lip it could pull down tree branches 22 ft. in the air. It lived during the Oligocene period of the age of mammals and appears to have been confined to Asia.

Placental Mammals.—From the standpoint of pure science possibly the most important specimens obtained by the expeditions were seven Cretaceous mammal skulls found at Shabarakh Ussu in the same formation which contained the dinosaur eggs. They represent the oldest truly placental mammals known. They were not larger than a small rat and crawled about in the middle of the Cretaceous era, the closing period of the age of reptiles, when dinosaurs still flourished. They may be regarded as the first attempt of nature to establish the insectivorous, herbivorous and carnivorous groups of mammals which were to become the dominant creatures of the earth.

Geology and Climate.—The geological work of the expeditions yielded most important results, the chief among them probably being the unravelling of the hitherto unknown major elements of geologic history of the Mongolian region and the working out of a fairly complete geologic column. It was learned that the structure of the Mongolian plateau consists of two great series of formations, separated by a profound unconformity. Those below the unconformity form a floor of ancient complex rock upon which the later sediments rest; many of these are fossil bearing. The geologists identified and described an enormous granite bathylith or underlying floor. This is not only important to "pure science" but it supports the inference that valuable mineral deposits are more likely to be found about the margins of the bathylith than in the area of broad exposure. The region has a basin-like character. There have been several mountain-making periods, several erosion periods and several revivals of volcanism.

The Gobi is essentially a rock desert with a very thin veneer of shifting sand and much bare rock. Interpretation of the strata indicates that this region has been continuously a continental area since early Mesozoic times; the sediments deposited since are all of continental type and not marine, being either fluvial, lacustrine or aeolian.

The reading of the history of climatic changes is one of the most important and interesting results of the expeditions and is the most extensive effort of its kind yet attempted in central Asia. The results achieved by Huntington in his study of the climatic changes of Pleistocene and recent time in other parts of Asia stand confirmed. Evidence is conclusive that this region has been arid and semi-arid in its climatic habit for many millions of years, but that there have been cycles of greater and less aridity. There is no indication that the regions ever experienced glaciation. In Pleistocene time, glacial epochs were represented in the Gobi region by changes to more humid climate, and inter-glacial epochs by return to desert conditions. The close of the glacial period and the beginning of recent time were marked by a change from comparative humidity to the desert climate of to-day. But even in recent time the climate has not been uniform; neither has the curve of change been smooth. There have been smaller changes within the longer cycles. Even within the last great arid cycle there have been epochs when the Gobi region was comparatively fruitful and could support a numerous population, separated by other epochs of more strictly desert habit and difficult conditions for animal life.

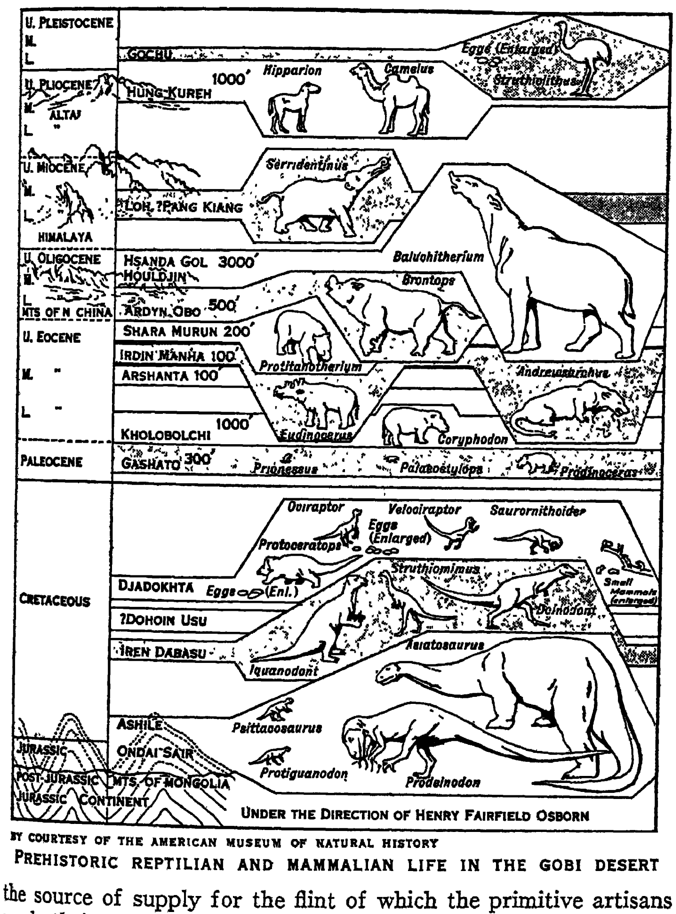
Archaeological Work, which was directed by Mr. N. C. Nelson, was not begun until the last expedition in the season of 1925. Rich results have rewarded the very beginning of the investigation of the central Asian plateau. During 1923, the Jesuits, Father Teilhard de Chardin and Father Licent, discovered abundant evidences of Palaeolithic man in extensive deposits of Mousterian implements at three different localities in the Ordos desert. No human remains were found with the exception of a single incisor tooth which has recently come to light, having remained unidentified among the collections of four years. Previous to this, Dr. J. G. Andersson had traced a widespread Neolithic and pre-Chinese culture in various parts of northern and western China proper. In 1926 two human teeth were described from a basal Pleistocene cave deposit in the Western hills about 15 m. from Peking, excavated under the direction of Dr. Andersson. In 1927 an additional molar tooth from the same deposit and doubtless from the same individual, a child about eight years old, was discovered during excavations conducted jointly by the Chinese Geological Survey and the Peking Union Medical college under the direction of Dr. Davidson Black. These teeth rank with the oldest human remains known to science.

Because caves and rock-shelters, so common in Europe, are virtually non-existent in Mongolia, archaeological work there is particularly difficult. Nevertheless, almost everywhere along the 1,000 m. route of the expedition from near Kalgan to the outlying ranges of the Altai mountains more or less superficial traces of two prehistoric cultures were discovered. In sight of the Altai, where workable artifact materials such as jasper, chalcedony and agate were abundant, there are evidences of long-standing occupation. In the Gobi desert were found five cultural horizons, not including the living Mongols. The most recent in age were monuments consisting of rectangular and circular rock enclosures, from 3 to 150 ft. across. Most of these are burial-places and several contained skeletal remains of a brachycephalic people. In one grave, Nelson discovered a skeleton with its head lying on a saddle, bows and arrows tipped with iron, bits of fabric and iron saddle trimmings. Near the graves were frequently pictographs pecked on the face of the rock. These represent human beings, camels, horses, cattle, stags, antelopes, ibexes and mountain sheep;

the stag is now absent there.

The meagre data obtained do not warrant any precise conclusions about this interesting culture but it seems probable that it is an expansion of the remarkable mound culture of Bronze and Iron age times uncovered by Russian investigators in the Upper Yenesei country. As such its Mongolian antiquity can scarcely exceed 2,000 years.

The "Dune Dwellers."—The most important archaeological discovery was a culture camp near the eastern spur of the Altai mountains within half a mile of the dinosaur egg beds. In fact, these primitive artisans used for necklace ornaments the broken shells of dinosaur eggs as well as those of *Struthiolithus*, the giant ostrich of the Stone age of Mongolia. No human fossils have been found, but it is established that the Stone age tribes spread over the borders of the Gobi desert region during the Ice age, establishing their workshops near large lakes bordering the Altai mountains. These Neolithic and Mesolithic people have been named by Mr. Nelson the "dune dwellers" or the "Shabarakh culture" because of the occurrence of their artifacts in old dead and indurated sand deposits called the "Shabarakh formation." It yields a combination of characters which appear to be distinctly Gobian. Thousands of flint artifacts and flakes were found here, both upon the surface and deeply embedded in the formation itself, and there are definite indications that this was a favourite camping place for many thousands of years. The geologists are certain that a lake had existed, probably intermittently, in this great basin furnishing water for the inhabitants. Moreover, 36 m. west was discovered



BY COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY

PREHISTORIC REPTILIAN AND MAMMALIAN LIFE IN THE GOBI DESERT

the source of supply for the flint of which the primitive artisans made their tools and weapons. That this culture was wide-spread is evident, for at nearly every place where the Shabarakh formation appeared, artifacts were present.

A still older upper Palaeolithic culture was discovered in two localities on old erosion surfaces composed of Quaternary gravels. It consisted of stone implements of Mousterian and Aurignacian types which resemble those found by Teilhard and Licent in the Ordos.

The Eolithic, or "Dawn Stage," of man's handiwork appears to be well represented in a number of places in Mongolia. There, on old erosion surfaces, composed of Quaternary gravels, lie thousands of fractured rocks and pebbles more or less weathered but showing successive stages of flaking. Whether or not any of these apparent artifacts actually are the result of human handiwork or whether they are all the work of natural agencies is difficult to determine; if any are of human origin they are of immense importance Nelson and Granger also spent two winters working along the Yangtze river in Szechuan, and in Yünnan province, and extended the pre-Chinese culture originally discovered by Andersson; but no remains of Palaeolithic man were found.

Zoology.—A small collection of birds was made; but investigations in zoology were confined to mammalogy, herpetology and ichthyology. The Asiatic expeditions in China proper and Mongolia have brought to the American Museum of Natural History 9,900 mammals, 11,666 reptiles and batrachians and 10,000 fish. Many new species have been discovered and important facts regarding the relationships and probable derivation of European and American living types demonstrated.

Photography occupied an important part in the expedition's activities. Every phase of the extensive work was recorded in still and motion pictures, as were also the life and customs of the natives. That the central Asian plateau was a great theatre of evolution for northern terrestrial life is now well established: that primitive men have existed in Mongolia since the close of the Pleistocene is certain: that this region was the home of early human types seems probable. The major geographical features of the Gobi have been determined, and a surveyed line of more than 1,000 m. has been run north-west through the heart of the desert. In the future similar investigations will be made in inner Mongolia, south of the Altai mountains. Rich sedimentary fossil bearing basins almost certainly lie in the western Gobi, and this region may yield important results in the study of human ancestry. *See* ASIA: *Archaeology*. (R. C. AN.)

History.—Mongolia has been the source of many invasions and raids into China, the most noted being the Mongol conquest in the 13th century. The Manchus extended their power over the country and made it part of the Chinese empire. The Mongols took advantage of the Chinese revolution of 1911 to oust the Chinese authorities from Urga and to declare their independence under the Hutukhtu (Living Buddha). This gave Russia her opportunity, and in 1912 she pledged her assistance in maintaining the independence of the Urga Government in return for special privileges. By an exchange of notes, China acknowledged the autonomy of Mongolia and Russia recognized that the Chinese were still suzerain. Chinese suzerainty was represented at Urga by a resident-general with deputies in three other places. Upon the collapse of Russia in 1918 the Chinese took steps to increase their power, and in 1919 Hsu Shu-tseng was appointed defence commissioner and coerced the Mongols into cancelling their autonomy. Early in Feb. 1921 Baron Ungern von Sternberg, leading a force made up of several nationalities and professing antagonism to the "Reds" in Russia, expelled the Chinese from Urga. The Living Buddha now returned, and an independent Mongol Government was proclaimed, with Ungern as chief military adviser. Ungern's troops revolted, he was defeated, captured and executed by Red forces (Aug. 1921), and Soviet Russia, while recognizing the Urga Government as independent, kept troops there. A treaty (Nov. 5, 1921) provided for Russian influence. By the Russo-Chinese treaty of May 31, 1924, Russia recognized Outer Mongolia as a part of China and agreed to withdraw her forces. However, the Mongols continued to claim their independence of China and in Nov. 1924 adopted a constitution of the soviet type, and Russia remained dominant. (*See* MONGOLS.)

MONGOLIAN LANGUAGE AND LITERATURE.

The Mongolian language, with Turki-Tatar and Tungus-Manchu, belongs to the Altaic family of languages. It has, roughly, three

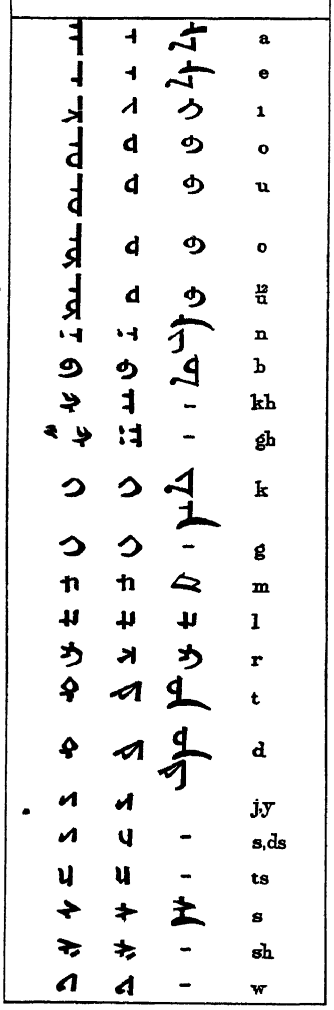
dialects: East Mongolian (Khalkha), West Mongolian (Kalmuk), and Buriatic, which differ but slightly.

The literary language is written vertically downwards, the lines following from left to right. The alphabet is very imperfect: *ger* (house) and *ker* (how), *urtu* (long) and *ordu* (palace), for instance, are written alike.

The word-order is almost the reverse of that of English. Nouns have six oblique cases: gen. *-yin, -ü(n)*; dat.-loc. *-dü(r), -e;* Acc. *-(y)ı;* ablat.*-eče;* instrum. *-ber, -iyer;* co-operat. *-lüge.* So also the pronouns *bi* (I), *či* (thou), *bide* (we), *ta* (ye), *ene* (this), *tere* (that), etc., but with certain modifications. The nominative of a noun is usually marked by *inu, anu* or *ber,* while the plural is expressed by *-ner, -(ü)d, -s,* etc. Adjectives are often used substantivally and are not declined for comparison. Verbs are conjugated for tenses and moods, but person and number are not expressed: ind. pres. and fut. *-mü(i)*, etc.; past *-be(i)*, etc.: optat. *-sü(gei)*, etc.; cond. *-basu, -besü.* The present participles are *-gči,* past part. *-gsen,* and fut. part. or infinitive *-qu, -kü.* Various adjunctive forms and the gerund ending in *-ǰü, -ged, -tele, -rün,* etc., are used. Negation is expressed by the adverbs *ülü, ese, ügei* and *buu* (imperative), and interrogation by *uu.* There are no prepositions, only postpositions. The sentences are joined by certain adjunctive and participial forms of the verb.

(E. D. R.)

MONGOLIAN LANGUAGE.



Literature.—Mongolian literature (including MANCHU), as an indigenous growth, is comparatively slight. A vast body of Buddhist and Confucian literature exists in excellent style, but most of the truly native literature is in the colloquial. Collections of native songs and folk-tales exist but these are not held in high esteem by the literati. The Mongolian *Siddhi-kür*, a collection of Buddhist tales, has been of use in restoring partly lost Indian originals. A number of Chinese novels and folk-stories have been translated in such a way as to obscure their real origin: the Mongol imagination is very vivid when dealing with fairy-tale themes. The Buddhist succession of hells gives the Mongol writers ample scope for the creation of weird and grisly characters, most convincing in their presentation. Historical works such as that of Sanang Setzen (17th century), a history of the Eastern Mongols and the *Altan Tobchi* stand very high in native and foreign esteem. The *Üliger ün dalai* (Sea of Comparisons) is the most important of all the religious works in Mongolian, while heroic literature is best represented by *Gesser Khan*, a legend of the hero of that name, with the poetic *Jangariad* as second favourite. Most of these works exist in excellent Russian and German translations, though some are only partly translated.

From the early part of the 17th century official documents were written in Chinese and Manchu, these two versions often carrying a Mongolian translation. The two words *San Ho* frequently found at the beginning of Chinese titles indicate that the work is trilingual, and the classics as well as popular works of fiction and poetry were early issued in this form. Before 1650 most of the existing dynastic histories of the Chinese empire had been translated into Manchu. One of the earliest independent works in Manchu was the *Han I Araha Ampasai Mutzilen Pe Dara Pure Bitkhe* (An address, from the Emperor to the Magistrates, on Moral Training) published in 1655. Strangely enough, very few works on the Tatars themselves were written, a noteworthy treatise being the *Jagôn gosai tung-tzi sutchung ga weileghe bitkhe* or Essay on the origin of the 8 Banners. The *Jalan Jalan i hafu puleku* or Mirror of Successive Generations gives a vivid historical picture of Tatar ambitions, and in this period only one work is known to us dealing with the Mongols, the *Kalkai dulimbi chugun gosa* (The Banners of the Khalkha Mongols). Works appeared on the arts of war and government and detailed account of Chinese embassies to different Tatar tribes. In the early 18th century bilingual collections of metaphors, proverbs and literary allusions began to appear and in 1732 was published the *Manju Nikan ghergen Kamtsiha sing li bitkhe* (Natural Philosophy in Manchu and Chinese).

From 1750 onwards various imperial commissions were engaged in translating commentaries on the orthodox classics and the text of heterodox philosophers. Where existing translations were deemed faulty new ones were undertaken at the charge of the Imperial Treasury and for over a century publication was continuous. In the last 80 years, however, little has been done to increase the bulk of literature in Manchu and Mongolian; one Mongolian newspaper has made its appearance but publication in the classical tongue (except for a few Scripture versions and Bible histories) ceased several decades ago. Chinese is rapidly becoming the native tongue of those who do not still cling to the debased Tibetan in use among the lamas, and has been recognized for some years as the literary tongue of Manchuria and Mongolia.

(A. N. J. W.)

MONGOLS, the name of one of the chief ethnographical divisions of the Asiatic peoples (*see* also TURKS). The early history of the Mongols, like that of all central-Asian tribes, is extremely obscure. Even the meaning of the name "Mongol" is a disputed point, though a general consent is now given to Schott's etymology of the word from *mong,* meaning brave. From the earliest and very scanty notice we have of the Mongols in the history of the T'ang dynasty of China (A.D. 619–690), and in works of later times, it appears that their original camping-grounds were along the courses of the Kerulen, Upper Nonni and Argun rivers. But in the absence of all historical particulars of their origin, legend, as is usual, has been busy with their early years. The Mongol historian, Sanang Setsen, gives currency to the myth that they sprang from a blue wolf; and the soberest story on record is that their ancestor Budantsar was miraculously conceived of a Mongol widow. By craft and violence Budantsar gained the chieftainship over a tribe living in the neighbourhood of his mother's tent, and thus left a heritage to his son. Varying fortunes attended the descendants of Budantsar, but on the whole their power gradually increased, until Yesukai, the father of Jenghiz Khan, who was eighth in descent from Budantsar, made his authority felt over a considerable area. For the extension of Mongol dominion under his son *see* JENGHIZ KHAN.

Ogdai Khan.—Over the whole of the vast region stretching from the banks of the Dnieper to the China Sea, Jenghiz Khan set his second surviving son Ogotai, or Ogdai, as khagan, or chief khan, while to the family of his deceased eldest son, Juji, he assigned the country from Kayalik and Khwarizm to the borders of Bulgar and Saksin "where'er the hoofs of Mongol horse had tramped"; to Jagatai, his eldest surviving son, the territory from the borders of the Uighur country to Bukhārā; while Tulē, the youngest, received charge of the home country of the Mongols,

the care of the imperial encampment and family, and of the archives of the State. The appointment of Ogdai as his successor, being contrary to the usual Mongol custom of primogeniture, caused some bitterness among the followers of Jagatai, but Ogdai was finally led to the throne by his dispossessed brother amid the plaudits of the assembled Mongols. Once fairly on the throne he set himself vigorously to follow up the conquests won by his father. At the head of a large army he marched southwards into China to complete the ruin of the Kin dynasty, which had already been so rudely shaken, while at the same time Tulē advanced into the province of Honan from the side of Shensi. Against this combined attack the Kin troops made a vigorous stand, but the skill and courage of the Mongols bore down every opposition, and over a hecatomb of slaughtered foes they captured Kai-fêng Fu, the capital of their enemies. From Kai-fêng Fu the emperor fled to Ju-ning Fu, whither the Mongols quickly followed. After sustaining a siege for some weeks, and enduring all the horrors of starvation, the garrison submitted to the Mongols, and at the same time the emperor committed suicide by hanging. Thus fell in 1234 the Kin or "golden" dynasty, which had ruled over the northern portion of China for more than a century.

His first essay in extending the empire in the fertile provinces of China meeting with such success, Ogdai remembered the obligation laid upon him by his father's conquests in Western Asia. Jelāl-ed-dīn had been driven into India when Jenghiz annexed Khwarizm, but he had returned with the support of the sultan of Delhi, reconquered his own domain and advanced westward to Tiflis and Kelat. Ogdai sent 300,000 men into Khwarizm; they marched so rapidly upon the foe that the advance-guards reached Amid (Jelāl-ed-dīn's retreat) before that monarch had any idea of their approach. Accompanied by a few followers, Jelāl-ed-dīn fled to the Kurdish mountains, where he was basely murdered by a peasant. The primary object of the Mongol invasion was thus accomplished; and, unchecked and almost unopposed, they overran the districts of Diarbekr, Mesopotamia, Erbīl and Kelat, and then advanced upon Azerbāijān. In the following year (1236) they invaded Georgia and Great Armenia, committing frightful atrocities. Tiflis was among the cities captured by assault, and Kars was surrendered at their approach. Meanwhile in 1235, Ogdai despatched three armies in as many directions. One was directed against Korea, one against the Sung dynasty, which ruled over the provinces of China south of the Yangtsze Kiang, and the third was sent westward under Batu into eastern Europe.

With irresistible vigour and astonishing speed the Mongols made their way through the forests of Penza and Tambov, and appeared before the "beautiful city" of Ryazan. For five days they discharged a ceaseless storm of shot from their balistas, and, having made a breach in the defences, carried the city by assault on Dec. 21, 1237. Moscow, at this time a place of little importance, next fell to the invaders, who then advanced against Vladimir, which at length succumbed. A dire fate overtook the inhabitants of Kozelsk, near Kaluga, where, in revenge for a partial defeat inflicted on a Mongol force, the followers of Batu held so terrible a "carnival of death" that the city was renamed by its captors Mobalig, "the city of woe." With the tide of victory thus strong in their favour the Mongols advanced against Kiev, "the mother of cities," and carried it by assault. The inevitable massacre followed and the city was razed to the ground.

Victorious and always advancing, the Mongols, having desolated this portion of Russia, moved on in two divisions, one under Batu into Hungary, and the other under Baidar and Kaidu into Poland. Without a check, Batu marched to the neighbourhood of Budapest, where the whole force of the kingdom was arrayed to resist him. While the careless Hungarians were sleeping, Batu launched his attack. Panic-stricken and helpless, they fled in all directions, followed by their merciless foe; the roads for two days' journey from the field of battle were strewn with corpses. The king, Bēla IV., was saved by the fleetness of his horse, though closely pursued by a body of Mongols, who followed at his heels as far as the coast of the Adriatic, burning and destroying everything in their way. Meanwhile Batu captured Budapest, and on Christmas day 1241, having crossed the Danube on the ice, took Esztergom by assault. While Batu had been thus triumphing, the force under Baidar and Kaidu had carried fire and sword into Poland. While laying waste the country they received the announcement of the death of Ogdai, and at the same time a summons for Batu to return eastwards into Mongolia.

While his lieutenants had been thus carrying his arms in all directions, Ogdai had been giving himself up to ignoble ease and licentiousness which ended in his death on Dec. 11, 1241. He was succeeded by his son Kuyuk, who reigned only seven years. On the death of Kuyuk, dissensions which had been for a long time smouldering between the houses of Ogdai and Jagatai broke out into open war, and after the short and disputed reigns of Kaidu and Chapai, grandsons of Ogdai, the lordship passed away for ever from the house of Ogdai. It did not go, however, to the house of Jagatai, but to that of Tulē.

Mangu Khan and Hulagu.—On July 1, 1251, Mangu, the eldest son of Tulē, and nephew to Ogdai, was elected khagan. With perfect impartiality, Mangu showed tolerance to the Christians, Mohammedans and Buddhists among his subjects although Shamanism was recognized as the State religion. Two years after his accession his court was visited by Rubruquis (q.v.) and other Christian monks, who were hospitably received. The description given by Rubruquis of the khagan's palace at Karakorum shows how wide was the interval which separated him from the nomad, tent-living life of his forefathers. On his accession complaints reached Mangu that dissensions had broken out in the province of Persia, and he therefore sent a force under the command of his brother Hulagu to punish the Ismailites or Assassins (q.v.), who were held to be the cause of the disorder. Marching by Samarkand and Karshi, Hulagu crossed the Oxus and advanced by way of Balkh into the province of Kuhistan or Kohistan. The terror of the Mongol name induced Rukneddin Gurshah II., the chief of the Assassins, to deprecate temporarily the wrath of Hulagu by offers of submission, but Rukneddin having been killed, 1256 (*see* Assassins), Hulagu marched across the snowy mountains in the direction of Baghdad to attack the last Abbasid caliph and his Seljuk protectors. On arriving before the town he demanded its surrender. This being refused, he laid siege to the walls in the usual destructive Mongol fashion, and at length, finding resistance hopeless, the caliph was induced to give himself up and to open the gates to his enemies. On Feb. 15, 1258, the Mongols entered the walls and sacked the city (*see* Caliphate *ad fin.*). While at Baghdad Hulagu gave his astronomer, Nāsir ed-din, permission to build an observatory, which, splendidly furnished with armillary spheres and astrolabes, was erected at Maragha. The fall of Baghdad was almost contemporaneous with the end of the Seljuks of Konia as an independent power, though their actual destruction did not take place until 1308 (*see* Seljuks). The Mongol invasion resulted in a famine which desolated 'Iraq-Arabi, Mesopotamia, Syria and Rūm. The Mongols did not starve with the people but went forward through Syria. Aleppo was sacked, Damascus surrendered (1260) and Hulagu was meditating the capture of Jerusalem to restore it to the Christians when news of Mangu's death reached him and he returned to Mongolia leaving Kitboga in command of his Syrian forces.

Hitherto a vassal of Mangu, as is shown by his striking coins bearing the name of Mangu as well as his own, Hulagu was now recognized as ruler of the conquered provinces. He assumed the title of ilkhan, and, although acknowledging the khagan as supreme lord, was practically independent. The title of ilkhan was that borne by his successors, who ruled over Persia for about a century (*v. infra*, "The Ilkhans of Persia").

While Hulagu was prosecuting these conquests in western Asia, Mangu and his next brother Kublai were pursuing a like course in southern China. Southward they even advanced into Tong-king, and westward they carried their arms over the frontier into Tibet. Under the wise command of Kublai all indiscriminate massacres were forbidden, and probably for the first time in Mongol history the inhabitants and garrisons of captured cities were treated with humanity. While carrying on the war in the province of Szechwan Mangu was seized with an attack of dysentery, which proved fatal after a few days' illness. His body was carried into Mongolia on

the backs of two asses, and, in pursuance of the custom of slaughtering everyone encountered on the way, 20,000 persons were, according to Marco Polo, put to the sword.

At the Kuriltai, or assembly of notables, which was held at Shang-tu after the death of Mangu, his brother Kublai (*see* KUBLAI KHAN) was elected khagan. For 35 years he sat on the Mongol throne, and at his death in 1294, in his 79th year, he was succeeded by his son Timur Khan (or Uldsheitu Khan, Chinese, Yuen-chêng). During this reign the division between the Ogdai and Jagatai families and that of the ruling khagan was healed. Uldsheitu was succeeded by his nephew Khaissan, who died in Feb. 1311, after a short reign, and at the early age of 31. His nephew and successor, Buyantu (Chinese, Yen-tsung), was a man of considerable culture, and substantially patronized Chinese literature. Among other benefits which he conferred on letters he rescued the celebrated inscription-bearing "stone-drums," which are commonly said to be of the Chou period (1122–255 B.C.), from the decay and ruin to which they were left by the last emperor of the Kin dynasty, and placed them in the gateway of the temple of Confucius at Peking, where they now stand. After a reign of nine years, Buyantu was succeeded by his son Gegen (Chinese, Ying-tsung), who perished in 1323 by the knife of an assassin. Yissun Timur (Chinese, Tai-ting-ti), who was the next sovereign, devoted himself mainly to the administration of his empire. He divided China, which until that time had been apportioned into 12 provinces, into 18 provinces, and rearranged the system of State granaries, which had fallen into disorder. His court was visited by Friar Odoric (q.v.), who gives a minute description of the palace and its inhabitants.

FROM HENRY YULE, "BOOK OF SER MARCO POLO" (JOHN MURRAY)

KUBLAI KHAN (A.D. 1216–1294), FROM A CHINESE ENGRAVING

The following years were years of great natural and political convulsions. In 1355 a Buddhist priest named Chu Yuen-chang became so impressed with the misery of his countrymen that he threw off his vestments and enrolled himself in the rebel army. His military genius soon raised him to the position of a leader, and with extraordinary success he overcame with his rude levies the trained legions of the Mongol emperor. While unable to defeat or check the rebels in the central provinces, Toghon Timur Khan was also called upon to face a rebellion in Korea. Nor were his arms more fortunate in the north than in the south. Toghon Timur, by a hasty flight, escaped from his enemies and sought safety on the shores of the Dolon-nor in Mongolia. For a time the western provinces of China continued to hold out against the rebels, but with the flight of Toghon Timur the Mongol troops lost heart, and in 1368 the ex-Buddhist priest ascended the throne as the first sovereign of the Ming or "Bright" dynasty, under the title of Hung-wu.

Thus ended the sovereignty of the house of Jenghiz Khan in China. Brave and hardy the Mongols have always shown themselves to be; but the capacity for consolidating the fruits of victory, for establishing a settled form of government, and for gaining the allegiance of the conquered peoples, has invariably been wanting in them.

Not content with having recovered China, the emperor Hung-wu sent an army of 400,000 men into Mongolia in pursuit of the forces which yet remained to the khagan. Even on their own ground the disheartened Mongols failed in their resistance to the Chinese, and at all points suffered disaster. Meanwhile Toghon Timur, who did not long survive his defeat, was succeeded in the khaganate by Biliktu Khan, who again, in 1379, was followed by Ussakhal Khan. During the reign of this last prince the Chinese again invaded Mongolia, and inflicted a crushing defeat on the khan's forces in the neighbourhood of Lake Buyur. This defeat was the final ruin of the eastern branch of the Mongols, who from this time surrendered the supremacy to the western division of the tribe. At first the Keraits or Torgod, as in the early days before Jenghiz Khan rose to power, exercised lordship over the eastern Mongols, but from these the supremacy passed to the Oirad, who for 50 years treated them as vassals. Notwithstanding their subjection, however, the Keraits still preserved the imperial line. Gradually, however, the Mongol tribes broke away from all governing centres, and established scattered communities with as many chiefs over the whole of eastern Mongolia. The discredit of having finally disintegrated the tribe is generally attached to Lingdan Khan (1604–34).

The Chakhars.—By this time the Mongols had recovered from the disaster suffered at the hands of the first Ming ruler. Driven to the north they retired to the banks of the Kerulen, their original home, but as the Chinese became weaker on the frontier they pushed southward and occupied the Ordos country. The Mongol royal family and their immediate surroundings occupied the Chakhar country to the north-west of the Ordos territory, where they became eventually subjugated by the Manchus who overthrew the Ming dynasty in 1644. At times the old vigour and strength seemed to return to the tribe, and we read of successful expeditions being made by the Ordos Mongols into Tibet, and even of invasions into China. The relations with Tibet thus inaugurated brought about a rapid spread of Buddhism among the Mongolians, and in the beginning of the 17th century a Dalai Lama was born among them. In 1625 Toba, one of the sons of Bushuktu Jinung Khan, went on a pilgrimage to the Dalai Lama, and brought back with him a copy of the Tanjur to be translated into Mongolian, as the Kanjur had already been.

Several of the tribes who had originally migrated with those who finally settled in the Ordos territory, finding the country to be so inhospitable, moved farther eastward into richer pastures. Among these were the Tumeds, one of whose chiefs, Altan Khan (Chinese, Yen-ta), is famous in later Mongol history for the power he acquired. During the 16th century he carried on continuous warfare with China, and on peace being made (1571) he was made a prince of the empire. He was as successful also in Tibet, and he brought back Lama prisoners who spread Lamaism through all the Tumeds. Altan died in 1584 and was succeeded by his son Senge Dugureng Timur.

The Khalkha Mongols.—North of the Gobi desert live the Eastern and Western Khalkhas. In the early 17th century the Russians sent an embassy to the khan persuading him to acknowledge allegiance to the tsar. The allegiance was lightly sworn and lightly thrown off, and when the Russians attacked the Khirghiz the Mongols aided the latter. In spite of submission to Russia the Mongols had no protection against Chinese attacks on the south and the Manchus demanded Mongol submission in their turn. When the Kalmucks began to menace them the Khalkhas claimed Chinese protection, and the emperor K'ang-hsi invited all the Khalkha chiefs to meet him on the plain of Dolon-nor. This ceremony resulted in the absorption of the Khalkhas into the Chinese race.

The Torgod.—During the Kin dynasty of China the Keraits, as has been pointed out, were for a time supreme in Mongolia, and it was during that period that one of the earliest recognized sovereigns, Merghus Buyuruk Khan, sat on the throne. A grandson of Merghus was the celebrated Wang Khan, who was sometimes the ally and sometimes the enemy of Jenghiz Khan, and has also been identified as the Prester John of early western writers. In war he was almost invariably unfortunate, and it was with no great difficulty, therefore, that his brother Ki Wang detached the greater part of the Kerait tribes from his banner and founded the Torgod chieftainship, named probably from the country where they settled themselves. Their history for several centuries consists of nothing but a succession of wars with the tribes on either side of them, and it was not until 1672, when Ayuka Khan opened relations with the Russians, that the country obtained an even temporarily settled existence. It was necessary, from the position of the territory, to conciliate either the Russians or the Turks. Frequent invasion from the north led to complaints of the tsar's government and friendly relations with the Krim Khan. Ayuka fought his way to Kazan and, having exacted full vengeance, made

peace with Russia, confirmed in 1722 at a conference with Peter the Great at Astrakhan. Ayuka was shortly succeeded by his son, Cheren Donduk, whose patent to the throne from the Dalai Lama did not protect him from the plots of his nephew, Donduk Ombo, who drove his uncle to St. Petersburg and seized the throne. Donduk Ombo governed wisely and with vigour, and was succeeded by Donduk Taishi, who went to Moscow to attend the coronation of the Empress Elizabeth and to swear fealty to the Russians. He was succeeded by his son Ubasha, who, in the war between his two powerful neighbours in 1769 and 1770, gave valuable assistance to the Russians. He determined to migrate eastward with his people, and on Jan. 5, 1771, he began his march with 70,000 families. In vain the Russians attempted to recall the fugitives, who, in spite of infinite hardships, after a journey of eight months reached the province of Ili, where they were welcomed by the Chinese authorities. Food for a year's consumption was supplied to each family; and land, money and cattle were freely distributed. It is believed that 300,000 persons survived to receive the hospitality of the Chinese. The Torgod prospered, but lost their individuality in absorption into the Chinese race.

The Kalmucks.—Among the Mongol chiefs who rose to fame during the rule of the Ming dynasty of China was Toghon, the Kalmuck khan, who, taking advantage of the state of confusion which reigned among the tribes of Mongolia, established for himself an empire in north-western Asia. He died in 1444 and was succeeded by his son, Yi-hsien, who was vigorous and ambitious. He attacked China and took the emperor (Chêng-t'ung) prisoner. Subsequent defeats made him open negotiations for the restoration of Chêng-t'ung. After Yi-hsien's death the Kalmucks lost much of their power in eastern Asia but still ravaged the Russian borders. In the 17th century Galdan restored some of their authority; taking advantage of a quarrel between the Black and White Mountaineers of Kashgar, he overran Little Bukhārā and left a viceroy there, with his capital at Yarkand. He made an alliance with China and then attacked the Khalkhas, but K'ang-hsi decided to support the Khalkhas. The Chinese marched into Mongolia and met Galdan's forces at Chao-modo where they routed them utterly. For a time Galdan strove to turn the tables on the Chinese but he died in the field, unsuccessful. Tsi-wang Arabtan, his successor, weakened his power by a dispute with the Russians over Little Bukhārā, said to be rich in gold. Peter the Great determined to force his way into the country and to oppose him the Kalmucks assembled in force. Tsi-wang's successor, Amursama, was appointed by the Chinese emperor K'ien Lung, who called him khan of the Kalmucks, and chief of Dzungaria (q.v.). But the real power was vested in Chinese commissioners, and Amursama revolted, dispersed the garrisons stationed in Ili and took Palikun. K'ien Lung sent a large force against the rebel and drove him into Siberia where he died of smallpox. China again absorbed a Mongol tribe, vying with Russia, her chief competitor in Mongol affairs. The Buriats, who occupied much territory on both sides of Lake Baikal, were not absorbed although they became "Russians."

The House of Jagatai.—The dominions given by Jenghiz Khan to his son Jagatai were involved in the quarrels between Kaidu and Kublai for the khaganate, but at the beginning of the 14th century Dua, a great-great-grandson of Jagatai, made himself undisputed lord of the whole region. Shortly after Dua's death the Mongols of eastern Turkistan, descendants of those who had favoured the pretensions of Kaidu to be khagan, separated from their western brethren and chose a son of Dua as their khan. Henceforth the Jagatais were divided into two dynasties, the western reigning at Samarkand, the eastern first at Kashgar and later at Yarkand and Aksu. Kazan (1343–46) was the last independent khan of the western Jagatais; thereafter power fell into the hands of amirs, who, however, continued to place a titular khan on the throne. In 1360 Toghluk-Timur, a grandson of Dua and khan of the eastern Jagatais (the kingdom called by the Persian historians Mogolistan), invaded the territories of the western Jagatais. About this time Timur (q.v.), otherwise Timur-i-leng (Tamerlane), a young amir at the court of the western Jagatais, allied himself with the leaders who had dethroned Kazan, and after the death of Toghluk-Timur became by right of conquest khan of both sections of the Jagatais. After Timur's death the two sections again divided, while a third kingdom, Ferghana, was held by the Timurids (descendants of Timur). At the beginning of the 16th century all three dynasties were swept away by Mohammed Shaībani, head of the Uzbeg Mongols (*v. infra,* "Uzbegs").

The Ilkhans of Persia.—The empire of the ilkhans established by Hulagu lasted nominally until 1353, but after the death of the ilkhan Abu Said in 1335 the real power was divided between five petty dynasties which had been formed out of the provinces conquered by Hulagu. Meantime Islam had made great progress among the Mongols, the third ilkhan, Nikudar Ahmed (reigned 1281–84), having embraced that faith. Upon the western frontiers of their empire bordering on the Syrian possessions of Egypt there was frequent intercourse, sometimes friendly, sometimes warlike, between the ilkhans and the sultans of Egypt (q.v.). Of the petty dynasties which supplanted that of Hulagu, one known as the Jelairids held Baghdad until about 1400. Another dynasty which reigned in Azerbaijan was overthrown in 1355 by the western Kipchaks (*v. infra,* "Golden Horde"). Between 1369 and 1400 Timur had made himself master of the greater part of Persia and established there a second Mongol dynasty, which in turn gave place to that of the Ak Kuyunli (*see* PERSIA).

The Golden Horde.—Of the Mongol tribes who became entirely subject to Russia the principal are those of the Crimea, of Kazan, and Astrakhan; of these the Tatars of Kazan are the truest representatives of the Golden Horde or western Kipchaks, who originally formed the subjects of Batu and Orda. Batu fixed his headquarters on the Volga, and there set up his golden tent from which the horde acquired its name. In 1255 Batu died and was succeeded by his brother, Bereke Khan. During the reign of this sovereign the exactions which were demanded from the Russian Christians by the Mongols aroused the Christian world against the barbarian conquerors, and at the command of Pope Alexander IV. a general crusade was preached against them. The crusaders, lacking unity, were surprised when a Tatar host, led by Nogai and Tulabagha, appeared in Poland. After a rapid and triumphant march the invaders took and destroyed Cracow, and thence advanced as far as Bythom (Beuthen) in Oppeln, from which point they eventually retired, carrying with them a crowd of Christian slaves.

From this time the Mongols became an important factor in European politics. They corresponded and treated with the European sovereigns, and intermarried with royal families. Hulagu married a daughter of Michael Palaeologus; Toktu Khan took as his wife Maria, the daughter of Andronicus II.; and to Nogai Michael betrothed his daughter Irene. Toktu, the second khan in succession to Bereke, is the first Mongol ruler of whom we hear as having struck coins. Those issued during his reign bear the mint marks of Sarai, New Sarai, Bulgar, Ukek, Khwarizm, Krim, Jullad and Madjarui, and vary in date from 1291 to 1312.

The adoption of Islam by the rulers of the Golden Horde drew closer the relations of the Mongols with Constantinople and Egypt. Nāṣir, ruler of Egypt, sent to demand in marriage a princess of the house of Jenghiz Khan. At first his request was refused by the proud Mongols, but the present of a million gold dinars, besides a number of horses and suits of armour, resulted in a princess landing at Alexandria in regal state in 1319. With that religious toleration common to his race, Uzbeg Khan, having married one princess to Nāṣir, gave another in marriage to George the prince of Moscow. Uzbeg protected the Russian churches within his frontiers, and put his seal to his new religious views by marrying a daughter of the Greek emperor, Andronicus III. He died in 1340, after a reign of 28 years. His coins were struck at Sarai, Khwarizm, Mokshi, Bulgar, Azak and Krim, and are dated from 1313 to 1340. His son and successor, Tinibeg Khan, after a reign of only a few months, was murdered by his brother, Janibeg Khan, who usurped his throne, which was snatched from him by violence in 1357. As he lay ill on his return from a successful expedition against Persia he was murdered by his son Berdibeg, who, in his turn was, after a short reign, murdered by his son Kulpa. With the death of Berdibeg the fortunes of the Golden Horde began

rapidly to decline.

The White Horde or Eastern Kipchak.—While the power of the Golden Horde was dwindling away, the White Horde or Eastern Kipchak, which was the inheritance of the elder branch of the family of Juji, remained vigorous and prosperous. The descendants of Orda, Batu's elder brother, maintained much of the simplicity and vigour of their nomad ancestors, and the throne descended from father to son with undiminished authority until the reign of Urus Khan (1360). Khan Tuli Khoja paid with his life for his temerity in opposing the political plans of his connection with Urus Khan. Toktamish, the son of the murdered man, fled at the news of his father's death and sought refuge at the court of Timur, who received him with honour and at once agreed to espouse his cause. With this intention he despatched a force against Urus Khan, and gained some advantage over him, but, while fitting out another army to make a fresh attack, news reached him of the death of Urus.

He was followed on the throne by his two sons, Tuktakia and Timur Malik, each in turn; the first reigned but for a few weeks, and the second was killed in a battle against Toktamish, the son of his father's enemy. Toktamish seized the throne (1378), not only of Eastern Kipchak but also of the Golden Horde, over which his arms had at the same time proved victorious. He reigned as Nāṣir ed-din Jetal el Mahmud Ghujas Toktamish. His demands for tribute from the Russian princes met with refusal, and Toktamish therefore at once marched an army into Russia. Having captured Serpukhov, he advanced on Moscow. On Aug. 23, 1382, his troops appeared before the doomed city, and a general slaughter followed. The same pitiless fate overtook Vladimir, Zvenigorod, Yuriev, Mozhaisk and Dimitrov. With better fortune, the inhabitants of Pereslavl and Kolomna escaped with their lives from the troops of Toktamish, but at the expense of their cities, which were burned to the ground. Flushed with success, Toktamish demanded from his patron Timur the restoration of Khwarizm, which had fallen into the hands of the latter at a period when disorder reigned in the Golden Horde. On Timur's refusal Toktamish marched an army of 90,000 men against Tabriz. After a siege of eight days the city was taken by assault and ruthlessly ravaged. In the meantime Timur was collecting forces to punish his rebellious protégé. When his plans were fully matured, he advanced upon Old Urgenj and captured it. More merciful than Toktamish, he transported the inhabitants to Samarkand, but in order to mark his anger against the rebellious city he levelled it with the ground and sowed barley on the site where it had stood. On the banks of the Oxus he encountered his enemy, and after a bloody battle completely routed the Kipchaks, who fled in confusion. A lull followed this victory, but in 1390 Timur again took the field. After a considerable delay, owing to an illness which overtook Timur, his troops arrived at Kara Saman. Here envoys arrived from Toktamish bearing presents and a message asking pardon for his past conduct; but Timur was inexorable. He marched forward month after month through the Kipchak country in pursuit of Toktamish. At last, on June 18, he overtook him at Kandurcha, in the country of the Bulgars, and at once forced him to an engagement. For three days the battle lasted, and finally the Kipchaks were completely routed and fled in all directions.

Toktamish, though defeated, was not subdued, and in 1395 Timur found it necessary again to undertake a campaign against him. This time the armies met upon the Terek, and after a fiercely contested battle the Kipchaks again fled in confusion. Timur, threatened by the advancing autumn, gave up further pursuit, and retired with a vast booty of gold ingots, silver bars, pieces of Antioch linen and of the embroidered cloth of Russia, etc. On his homeward march southwards he arrived before Azak, which was then the entrepôt where the merchants of the east and west exchanged their wares. In vain the natives, with the Egyptian, Venetian, Genoese, Catalan and Basque inhabitants, besought him to spare the city. Circassia and Georgia next felt his iron heel, and the fastnesses of the central Caucasus were one and all destroyed. Timur rested for a time in luxurious splendour and then marched against and utterly destroyed Aṣtrakhan. Sarai was similarly treated and Timur having destroyed the empire of Toktamish for the second time returned home.

The Krim Tatars.—The power in the hands of the successors of Toktamish never revived after the last campaign of Timur. They were constantly engaged in wars with the Russians and the Krim Tatars, with whom the Russians had allied themselves, and by degrees their empire decayed, until, on the seizure and death of Ahmad Khan at the beginning of the 16th century, the domination of the Golden Horde came to an end.

The fate which thus overtook the Golden Horde was destined to be shared by all the western branches of the great Mongol family. The khans of Kazan and Kasimov had already in 1552 succumbed to the growing power of Russia, and the Krim Tatars were next to fall under the same yoke. In 1453 Constantinople had been taken by the Osmanli Turks, who, having quarrelled with the Genoese merchants who monopolized the trade on the Black sea, sent an expedition into the Crimea to punish the presumptuous traders. The power which had captured Constantinople was not likely to be held in check by any forces at the disposal of the Genoese, and without any serious opposition Kaffa, Sudak, Balaklava and Inkerman fell before the troops of the sultan Mohammed. It was plain that, situated as the Crimea was, between the two great powers of Russia and Turkey, it must of necessity fall under the direction of one of them. Which it should be was decided by the invasion of the Turks, who restored Mengli Girai, the deposed khan, to the throne and virtually converted the khanate into a dependency of Constantinople. But though under the tutelage of Turkey, Mengli Girai, whose leading policy seems to have been the desire to strengthen himself against the khans of the Golden Horde, formed a close alliance with the grand-prince Ivan of Russia. Mohammed Girai Khan in 1521 marched an army northwards until, after having devastated the country, massacred the people, and desecrated the churches on his route, he arrived at the heights of Vorobiev overlooking Moscow. A treaty was arranged by which the grand-prince Basil undertook to pay a perpetual tribute to the Krim khans. Before long, however, a contention arose over the khanate of Kazan, recovered by the Mongols and lost again to Russia together with Astrakhan in 1555. The sultan, however, declined to accept this condition of things as final, and instigated Devlet Girai, the Krim khan, to attempt their recovery. On arriving before Moscow walls the latter found a large Russian force occupying the suburbs. With these, however, he was saved from an encounter, for just as his foremost men approached the town a fire broke out, which, in consequence of the high wind

MEDIAEVAL TATAR HUTS AND WAGONS. A PAVILION OF WANDS, COVERED WITH CLOTH, IS SHOWN; ERECTED ON A LARGE WAGON DRAWN BY 22 OXEN

blowing at the time, spread with frightful rapidity and in the space of six hours destroyed all the churches, palaces and houses, with the exception of the Kremlin, within a compass of 30 miles. Another invasion of Russia, a few years later (1572), was not so fortunate for the Mongols, who suffered a severe defeat near Molodi, 50 versts from Moscow. A campaign against Persia made a diversion in the wars which were constantly waged between the Krim khan and the Russians, Cossacks and Poles. So hardly were these last pressed by their pertinacious enemies in 1649 that they bound themselves by treaty to pay an annual subsidy to the khan.

But the fortunes of war were not always on the side of the Tatars, and with the advent of Peter the Great to the Russian throne the power of the Krim Mongols began to decline. In 1696 the tsar, supported by a large Cossack force under Mazeppa, took the field against Selim Girai Khan, and gained such successes that the latter was compelled to cede Azov to him. By a turn of the wheel of fortune the khan had the satisfaction in 1711 of having it restored to him by treaty; but this was the last real success that attended the Tatar arms. In 1735 the Russians in their turn invaded the Crimea, captured the celebrated lines of Perekop, and ravaged Bakhchi-sarai, the capital. In 1783 the Krim, together with the eastern portion of the land of the Nogais, became absorbed into the Russian province of Taurida.

The Uzbegs.—The Uzbegs on the destruction of the Golden Horde, assumed an important position on the east of the Caspian sea. The founder of their greatness was the khan Abulkhair, who reigned in the 15th century, and who consolidated a power out of a number of small clans. Shaibani Khan, his grandson, proved himself a worthy successor, and by him Baber (q.v.), the Timurid khan of Ferghana, who afterwards founded the Mogul empire in India, was driven from his ancestral dominions. In 1500 he inflicted a severe defeat on Baber's forces, and captured Samarkand, Herat and Kandahar. By these and other conquests he became possessed of all the country between the Oxus and the Jaxartes, of Ferghana, Khwarizm and Hissar, as well as of the territory of Tashkent from Kashgar to the frontiers of China. In the following year, by a dashing exploit, Baber recovered Samarkand, only to lose it again a few months later. During several succeeding years Shaibani's arms proved victorious in many fields of battle, and but for an indiscreet outrage on the territories of the shah of Persia he might have left behind him a powerful empire. The anger, however, of Shah Ismail roused against him a force before which he was destined to fall. The two armies met in the neighbourhood of Merv, where, after a desperate encounter, the Uzbegs were completely defeated. Shaibani, with a few followers, sought refuge in a cattle-pound. But finding no exit on the farther side, the refugees tried to leap their horses over the wall. In this attempt Shaibani was killed (1510). After this defeat the Uzbegs withdrew across the Oxus and abandoned Khurāsān. Farther east the news aroused Baber to renewed activity, and before long he re-occupied Samarkand and the province "beyond the river," which had been dominated by the Uzbegs for nine years. But though the Uzbegs were defeated they were by no means crushed, and ere long we find their khans reigning, now at Samarkand, and now at Bukhārā. As time advanced and European powers began to encroach more and more into Asia, the history of the khanates ceases to be confined to the internecine struggles of rival khans. Even Bukhārā was not beyond the reach of Russian ambition and English diplomacy. Several European envoys found their way thither during the first half of the 19th century, and the murder of Stoddart and Conolly in 1842 forms a melancholy episode in British relations with that fanatical capital. With the absorption of the khanate of Bukhārā and the capture of Khiva by the Russians the individual history of the Mongol tribes in central Asia comes to an end, and their name has left its imprint only on the dreary stretch of Chinese-owned country from Manchuria to the Altai mountains, and to the equally unattractive country in the neighbourhood of the Koko-nor. The Mongols have become scattered nomads engaged in agriculture and caravan trading, and are now for the most part indistinguishable from the Chinese who surround them everywhere.

MONGOOSE, the name applied to the Indian representatives of the weasel-like mammals of the genus *Herpestes* (*see* Ichneumon). The Indian mongoose (*H. mungo*) is smaller than the Egyptian animal, with fur of a brownish-grey colour, the hairs being largely white-ringed, while the cheeks and throat are more or less reddish. It is especially serviceable in India as a serpent-killer, destroying not only the eggs and young of these creatures but killing the most venomous adult snakes. The mongoose is not immune to the snake's poison, falling a victim as rapidly as any other animal when bitten. By its agility and quickness of eye, it avoids the fangs of the snake while fixing its own teeth in the back of the reptile's neck. Moreover, when excited, the mongoose erects its long stiff hair, and it must be difficult for a snake to drive its fangs through this and the thick skin which all the members of the genus possess. The mongoose is equally dexterous in killing rats and other vermin. For the effects of the introduction of the Mongoose into Jamaica, *see* F. Finn, *Wild Animals of Yesterday and To-day,* 1st edit., London.

MONISM, in philosophy, generally denotes any ontological theory according to which all that exists is in some sense one (Gr. μονος, one). The term monism was first introduced by the German philosopher C. Wolff (1679–1754), but came into vogue chiefly through the influence of Haeckel and Ostwald, the leaders of the "Society of Monists" (*Monistenbund*) founded in 1906. Wolff used the term monism simply in contrast to dualism, and he recognized only two kinds of monism, namely, materialism and idealism. Since then, however, the term has received many other applications, and the present varieties of monism are legion. It is not proposed to do more here than to indicate briefly the most important of them. To avoid unnecessary complication and confusion it is perhaps best to follow the more usual tendency and to restrict the term monism to what is sometimes called "substantival" monism. Substantival monism is the view that reality is just one substance or self-existing thing or system, and that all things and events of daily experience are but parts or modifications of this ultimate substance. Besides "substantival" monism there is "attributive" monism, that is the view that reality has but one *irreducible* attribute. Now, attributive monism, as will be seen presently, may or may not be combined with substantival monism, and it may also be combined with substantival pluralism (the view that there is more than one ultimate substance). Idealistic monism combines substantival with attributive monism; Spinoza's monism combines substantival monism with attributive pluralism (that is the recognition of more than one irreducible attribute in ultimate reality); and the monodology of Leibnitz combines attributive monism with substantival pluralism. But to return to the main types of substantival monism. Differences in substantival monism must obviously be correlated with differences in the character attributed to the one ultimate reality which all forms of substantival monism admit. Now the most familiar kinds of reality are those commonly described as the material and the mental (or body and mind, or extension and thought, etc.). Hence the most common differences in ontology, and therefore in substantival monism. are connected with these characters or attributes. The monism which identifies ultimate reality with matter or with physical energy is called *materialism* or *energism* or energetic monism. That which identifies it with mind or experience is called *spiritual* or *psychical* monism; and if it identifies ultimate reality more particularly with reason or thought, it is called *idealistic* or *intellectualistic* monism, and if with will, it is called *voluntarism* or *voluntarist* monism. Then there are varieties of monism which maintain that ultimate reality is itself neither material nor psychical (or spiritual), and that it only expresses itself in these two parallel ways, and may be in many, or infinite other ways. These may be called *dualistic* or *pluralistic* forms of monism according as they combine attributive dualism or pluralism with substantival monism. But they are known by various other names, some of which and the reasons for them may be stated here. One name is *agnostic* monism, because the nature of ultimate reality is unknown, apart from its material and mental manifestations. Another name is *neutral* monism, because ultimate reality is regarded as being itself neither material nor mental, though expressing itself in both these ways. Sometimes it is called the *identity philosophy* or the *mind-stuff theory* (*q.v.*), because the material and mental are regarded

as having something identical or an identical source, or because the same ultimate entity is at once mind and matter. And so on. Before proceeding to other considerations it may be as well to note an important difference between these dualistic or pluralistic types of monism, on the one hand, and the materialistic and spiritualistic types, on the other. According to the former the material and the mental are equally real—neither is reducible to the other. Materialism, on the other hand, reduces the mental to a mere epiphenomenon (or by-product) of matter or physical energy; and idealistic or psychical monism reduces the material to a merely mental appearance. It is true, however, that even the dualistic or pluralistic types of monism show some of them a tendency to stress the mental side and so lean towards idealism, while others stress the material side and so lean towards materialism. The next ground of difference between types of monism turns on the answer to the question whether there is any purposiveness in the processes of ultimate reality? If the answer is affirmative, we have *teleological* monism; if negative we have either *mechanistic* or *naturalistic* monism. Lastly, there is the question of its divinity. If this is denied, we have *atheistic* monism; if it is affirmed, as it is in the monism of Spinoza who identified Nature or the Universe (or Substance) with God, then we have *pantheism* or pantheistic monism.

MONITION or **ADMONITION,** in English ecclesiastical law, an order requiring or admonishing the person complained of to do something specified in the monition, or appear and show cause to the contrary, "under pain of the law and penalty thereof." It is the lightest form of ecclesiastical censure, whether to clergymen or laymen, but disobedience to it, after it has been duly and regularly served, entails the penalties of contempt of court. Monitions of a disciplinary character are either for the purpose of enforcing residence on a benefice or in connection with suits to restrain ritual alleged to be unlawful.

MONITOR: NAVAL, a shallow draught warship mounting one or two very large guns and specially designed for bombarding. Credit for the idea of a vessel of this type may perhaps be given to Captain Cowper Coles who, in 1855, during the Crimean War, mounted a 32 pounder on a raft. Incidentally he also evolved the system of training a gun on a turntable with a winch instead of levering the carriage round with hand-spikes or pulling it right and left with tackles, thereby originating what eventually developed into the modern form of gun mounting.

The most famous ship of this class of her day and the one which gave the name "Monitor" to the type was that built to Ericsson's design in 1861. (*See* below "MONITOR" AND "MERRIMAC," BATTLE OF.)

Monitors in embryo form were to be found in the British fleet in the bomb ketches introduced in the 17th century, afterwards increased in size to bomb vessels known as "bombs." These craft were used in the frequent coastal operations of those days and formed a definite feature amongst the various types which composed the navy. At a later date we find the principle of the design embodied in the old coast defence ships of the "Cyclops" class. These were built as the result of an entirely unsound policy whereby naval units were dotted along the coast with the idea that they produced some measure of local protection, whereas, of course, the money would have been far better devoted to increasing the seagoing fleet. But the conception of a "coast attack" ship as distinct from a sort of mobile defensive fort was an entirely sound one and naval history has repeatedly shown the necessity for such a type. The World War was no exception in this respect. The operations on the Belgian Coast, in the Dardanelles, in the Suez Canal and in various inland waterways all called for small warships of the monitor type, and the British navy was not found to be at all well equipped in this respect. In fact, at the outbreak of hostilities the only craft resembling monitors were the old flat-iron gun-boats like the "Excellent" and the "Bustard," which were at once pressed into service on the Belgian Coast (*q.v.*). There were, however, three shallow-draught gun-boats building in this country for the Brazilian Government and these were immediately purchased and commissioned as the "Humber," "Mersey" and "Severn" for similar service. Before the end of the year, however, under the auspices of Admiral of the Fleet Lord Fisher a number of monitors, large and small, were laid down. They were probably intended by him to be used for his great landing project in the Baltic, but before that could be given serious consideration urgent claims arose for their services in the other war areas already mentioned.

On the Belgian Coast, old sloops, and, from time to time, an old battleship, were, at first, used for coastal bombarding and proved their unsuitability. In the Dardanelles, where old battleships had been mostly employed for this purpose, the toll of their destruction was heavy, and gave striking proof of the unreadiness of the navy for this form of amphibious warfare and of how the lessons of the past had been forgotten in centring thought and effort exclusively on building up the main fleet.

The new monitors, which were built in record time, saw much active service and proved their success as a type both by the effectiveness of their gun fire and by their remarkable immunity from casualties. The larger class, carrying a pair of 12, 14 or 15 inch guns each, were, probably, more often in action than any other vessels carrying turret guns. They were all fitted with bulges to protect them against torpedo attack. One ship, H.M.S. "Terror," was hit by no less than three torpedoes which exploded in quick succession in the fore part, but she succeeded in getting to Portsmouth from the Belgian Coast and was repaired and back on her station in a few weeks. H.M.S. "Erebus," a sister ship, was hit amidships by an explosive boat carrying a very large charge. She steamed to Portsmouth at 12 knots and was back on the Belgian Coast in a fortnight. One large monitor, H.M.S. "Raglan," was caught unawares by the German battle cruiser "Goeben" off Imbros and sunk by gun fire, while a second, H.M.S. "Glatton," was lost through catching fire and having to be torpedoed to avoid her magazines exploding in Dover Harbour. But these were the only casualties out of a fleet of sixteen of this type, of which three have been retained in the post-war fleet (1928). The monitor, as a type, was represented in the United States navy until after the World War, but with the exception of one ship, the "Cheyenne," used (1928) as a training ship, the vessels of this class have been scrapped. (E. A.)

"MONITOR" AND "MERRIMAC," BATTLE OF, a naval engagement which was fought early in the American Civil War, notable as the first conflict between iron-clad vessels. In the spring of 1861 the Federals set fire to several war vessels in the Gosport navy yard on the Elizabeth river (Va.) and abandoned the place. In June the Confederates set to work to raise one of these abandoned vessels, the frigate "Merrimac" of 3,500 tons and 40 guns, and to rebuild it as an iron-clad. The vessel (renamed the "Virginia" though she is generally known in history by her original name) was first cut down to the water-line and upon her hull was built a rectangular casemate, constructed of heavy timber (24 in. in thickness), covered with bar-iron 4 in. thick, and rising from the water on each side at an angle of about 35°. The iron plating extended 2 ft. below the water-line; and beyond the casemate, toward the bow, was a cast-iron pilot house, extending 3 ft. above the deck. The reconstruction of the vessel was completed on March 5, 1862. She drew 22 ft. of water, was equipped with poor engines, so that she could not make more than 5 knots, and was so unwieldy that she could not be turned in less than 30 minutes. She was armed with 10 guns—2 (rifled) 7 in., 2 (rifled) 6 in., and 6 (smooth bore Dahlgren) 9 in. Her most powerful equipment, however, was her 18 in. cast-iron ram.

In Oct. 1861 Capt. John Ericsson, an engineer, and a Troy, N.Y., firm, as builders, began the construction of the iron-clad "Monitor" for the Federals, at Greenpoint, Long Island. For the idea of the low free-board and the revolving turret Ericsson was indebted to Theodore R. Timby (1819–1909), who in 1843 had filed a caveat for revolving towers for offensive or defensive war-

fare, whether placed on land or water. With a view to enable this vessel to carry at good speed the thickest possible armour compatible with buoyancy, Ericsson reduced the exposed surface to the least possible area. Accordingly, the vessel was built so low in the water that the waves glided easily over its deck except at the middle, where was constructed the revolving turret for the guns, and though the vessel's iron armour had a thickness of 1 in. on the deck, 5 in. on the side, and 8 in. on the turret, its draught was only 10 ft. 6 in., or less than one-half that of the "Merrimac." Its turret, 9 ft. high and 20 ft. in inside diameter, seemed small for its length of 172 ft. and its breadth of 41 ft. 6 in., and this, with the lowness of its freeboard, caused the vessel to be called the "Yankee cheese-box on a raft." Forward of the turret was the iron pilot house, square in shape, and rising about 4 ft. above the deck. The "Monitor's" displacement was about 1,200 tons and her armament was two 11 in. Dahlgren guns; her crew numbered 58, while that of the "Merrimac" numbered about 300. She was seaworthy in the shallow waters off the southern coasts and steered fairly well. The "Monitor" was launched at Greenpoint, Long Island, Jan. 30, and was turned over to the Government on Feb. 19. The building of the two vessels was practically a race between the two combatants.

On March 8, about 1 P.M., the "Merrimac," commanded by Commodore Franklin Buchanan (1800–1874), steamed down the Elizabeth accompanied by two one-gun gun-boats, to engage the wooden fleet of the Federals, consisting of the frigate "Congress," 50 guns, and the sloop "Cumberland," 30 guns, both sailing-vessels, anchored off Newport News, and the steam frigates "Minnesota," and "Roanoke," the sailing-frigate "St. Lawrence," and several gun-boats, anchored off Fortress Monroe.

Actual firing began about 2 o'clock, when the "Merrimac" was nearly a mile from the "Congress" and the "Cumberland." Passing the first of these vessels with terrific broadsides, the "Merrimac" rammed the "Cumberland" and then turned her fire again on the "Congress," which in an attempt to escape ran aground and was there under fire from three other Confederate gun-boats which had meanwhile joined the "Merrimac." At about 3.30 P.M. the "Cumberland," which had been keeping up a heavy fire at the Confederate vessels, sank, with "her pennant still flying from the topmast above the waves." Between 4 and 4.30 the "Congress," having been raked fore and aft for nearly an hour by the "Merrimac," was forced to surrender. While directing a fire of hot shot to burn the "Congress," Commodore Buchanan of the "Merrimac" was severely wounded and was succeeded in the command by Lieutenant Catesby ap Roger Jones. The Federal steam frigates, "Roanoke," "St. Lawrence" and "Minnesota" had all gone aground in their trip from Old Point Comfort toward the scene of battle, and only the "Minnesota" was near enough (about 1 m.) to take any part in the fight. She was in such shallow water that the Confederate iron-clad ram could not get near her at ebb tide, and at about 5 o'clock the Confederates postponed her capture until the next day and anchored off Sewell's Point.

The "Monitor," under Lieutenant John Lorimer Worden (1818–97), had left New York on the morning of March 6; after a dangerous passage in which she twice narrowly escaped sinking, she arrived at Hampton Roads during the night of the 8th, and early in the morning of the 9th anchored near the "Minnesota." When the "Merrimac" advanced to attack the "Minnesota," the "Monitor" went out to meet her, and the battle between the iron-clads began at about 9 A.M. on the 9th. Neither vessel was able seriously to injure the other. The "Monitor" had the advantage of being able to out-manoeuvre her heavier and more unwieldy adversary; but the revolving turret made firing difficult, and communications were none too good with the pilot house, the position of which on the forward deck lessened the range of the two turret-guns. The machinery worked so badly that the revolution of the turret was stopped. After two hours' fighting, the "Monitor" was drawn off, so that more ammunition could be placed in the turret. When the battle was renewed (at about 11.30) the "Merrimac" began firing at the "Monitor's" pilot house; and a little after noon a shot struck the sight-hole of the pilot house and blinded Lieutenant Worden. The "Monitor" withdrew in the confusion consequent upon the wounding of her commanding officer, and the "Merrimac" after a short wait for her adversary steamed back to Norfolk. There were virtually no casualties on either side. After the evacuation of Norfolk by the Confederates on May 9, Commodore Josiah Tattnall, then in command of the "Merrimac," being unable to take her up the James, sank her. The "Monitor" was lost in a gale off Cape Hatteras on Dec. 31, 1862.

Though the battle between the two vessels was indecisive, its effect was to "neutralize" the "Merrimac," which had caused great alarm in Washington, and to prevent the breaking of the Federal blockade at Hampton Roads; in the history of naval warfare it may be regarded as marking the opening of a new era—the era of the armoured warship.

MONITORING RECEIVER is a receiver so arranged as to enable an operator to check the operation of a radio transmitting set.

MONK (or MONCK), GEORGE, 1ST DUKE OF ALBEMARLE (1608–1669), second son of Sir Thomas Monk, was born at Potheridge, near Torrington, in Devonshire, on Dec. 6, 1608. In 1626 he served in the expedition to Cadiz, and the next year in the Isle of Ré. At the outbreak of the Irish rebellion he was made colonel of Lord Leicester's regiment. All the qualities for which he was noted—his talent for making himself indispensable, his imperturbable temper and his impenetrable secrecy—were fully displayed in this employment. Monk was appointed governor of Dublin by Leicester, but Charles I. overruled the appointment in favour of Lord Lambert. Ormonde, who viewed Monk with suspicion as one of the two officers who refused the oath to support the Royal cause in England, sent him under guard to Bristol. But he justified himself to Charles in person, and his soldierly criticisms on the Irish War impressed the king, who gave him a command in the corps sent over from Ireland during the English Civil War. He was taken prisoner, at Nantwich (1644), and spent the next two years in the Tower, where he wrote his *Observations on Military and Political Affairs.*

Monk's Irish experience led to an invitation to serve parliament against the Irish rebels. At first as adjutant-general to the Parliamentary lord-lieutenant, his old friend Lord Lisle, and afterwards as governor of Ulster, he rendered great services to his new masters. He made head against the rebels for two years, but in the third (1649) the Parliamentarians, weakened by defections brought about by the execution of the king, lost one place after another, and Monk concluded an armistice with the rebel Owen Roe O'Neill upon terms which he knew would not be ratified. Having been exonerated by parliament, his next command was in Cromwell's army in Scotland. He commanded a brigade at the victory of Dunbar, and when in 1651 Cromwell hurried into England to pursue Charles II., Monk was left to complete the subjugation of the country. After taking Dundee, he retired to Bath in 1652, broken in health.

In Nov. 1652 Monk was appointed one of the three generals of the fleet. He was engaged with Blake and Deane in the battle of Portland (Feb. 18, 1653), and in the action of June 2–3 exercised the general command after Deane's death. A third battle on July 29 and 30, was a decisive victory for the Commonwealth's fleet (*see* DUTCH WARS). On his return he married Anne Clarges, a woman of low extraction, and next year was back in Scotland. After suppressing the Royalist insurrection in the Highlands, he settled down to a steady government of the country for the next five years. In 1655 he received a letter from Charles II., a copy of which he sent to Cromwell, who is said to have replied in 1657: "There be that tell me that there is a certain cunning fellow in Scotland called George Monk, who is said to lye in wait there to

introduce Charles Stuart; I pray you, use your diligence to apprehend him, and send him up to me."

During the confusion which followed Cromwell's death Monk remained watchful at Edinburgh, careful only to secure his hold on his troops. In July 1659 tempting proposals were again made to him by the king, but he would not entertain them. When Booth rose in Cheshire for the king, Monk was on the point of joining forces with him, and a manifesto was prepared. His habitual caution, however, induced him to wait until the next post from England, and the next post brought news of Booth's defeat.

When Fleetwood and Lambert declared against the parliament, Monk refused to join them, and (Oct. 20, 1659) at once took measures of active opposition. Securing his hold on Scotland by a small corps of occupation, he crossed the border with the rest of his army. Holding Lambert in play until his army began to melt away for want of pay, Monk became commander-in-chief of the parliament's forces (Nov. 24). The navy, some of the English garrisons and the army in Ireland declared for the parliament, and the army from Scotland crossed the Tweed on Jan. 2, 1660. Monk entered London on Feb. 3. In all this his ultimate purpose remained mysterious. At one moment he secretly encouraged the demands of the Royalist City of London, at another he urged submission to the existing parliament, then again he refused to swear an oath abjuring the house of Stuart, and further he hinted to the attenuated Long Parliament the necessity of a dissolution. Lastly, acting as the military agent of the infuriated parliament, he took away the gates and portcullises of the city. This angered not only the citizens but his own army, and gave him the lever that he desired to enforce the dissolution of parliament. He was now master of the situation, and though he proclaimed his republican sympathy, it was well known that the new parliament, which Monk was imposing on the remnant of the old, would have a strong Royalist colour. Monk himself was now in communication with Charles II., whose declaration of Breda was based on Monk's recommendations. The new parliament met on April 25, and on May 1st voted the restoration of the monarchy.

With the Restoration the historic interest of Monk's career ceases. Soldier as he was, he had played the difficult game of diplomacy with incomparable skill, and had won it without firing a shot. He was made gentleman of the bedchamber, knight of the Garter, master of the horse and commander-in-chief, raised to the peerage with the titles of Baron Monk, earl of Torrington and duke of Albemarle, and received a pension of £7,000 a year. Monk had been appointed lord-lieutenant of Ireland but he would not leave England. He concurred in the disbandment of the army, and only the regiment of which he was colonel, the Coldstream (Guards), survives to represent the army of the Civil Wars. In 1664 he had charge of the admiralty when James, duke of York, was in command of the fleet, and when in 1665 London was deserted on account of the plague, Monk remained in charge of the government of the city. In the following July, with Rupert, he defeated the Dutch fleet, and in the autumn maintained order in London during the Great Fire. His last service was in 1667, when the Dutch fleet sailed up the Thames, and Monk, though ill, hastened to Chatham where he was unable to oppose their progress. From that time he lived in privacy, and died of dropsy on Jan. 3, 1670. The dukedom became extinct on the death of his son Christopher, 2nd duke of Albemarle (1653–88).

See the *Life* of Monk, by Dr. Gumble, his chaplain (1671), and the memoir and bibliography by C. H. Firth in the *Dict. Nat. Biogr.*

MONK, a member of a community of men living a life under vows of religious observance; the term is properly confined to a member of a Christian community, but is sometimes applied to members of Buddhist and Mohammedan religious brotherhoods. The Greek and Latin name was first used of the hermits, but was early widened to embrace the coenobites. (*See* MONASTICISM.)

MONKEY, a term applicable to all members of the order PRIMATES (*q.v.*) except man and, strictly, the true or anthropoid apes.

MONKEY-NUT: *see* GROUND-NUT.

MONKEY PUZZLE, the name given to the Chile pine (*Araucaria imbricata*) introduced into Great Britain in 1796 and since widely cultivated throughout Europe and the southern United States, especially in California. The tree grows to a height of 150 ft. in the Cordilleras of Chile. The stiff, sharp-pointed leaves, 1 in. to 2 in. long, with broad overlapping (imbricated) bases, persist for many years. The globose cones are from 8 to 8½ in. broad and 7 to 7½ in. long; the wood is hard and durable.

MONKHOUSE, WILLIAM COSMO (1840–1901), English poet and critic, was born in London on March 18, 1840. He was educated at St. Paul's School, and entered the civil service. In 1870–1871 he went on a mission to South America and he served on different departmental committees, notably that of 1894–1896 on the Mercantile Marine Fund. He died in London on July 20, 1901. His first book of poems, *A Dream of Idleness and Other Poems* (1865), is strongly coloured by his admiration for Wordsworth and Tennyson. His other poetical works are *Corn and Poppies* (1890), *The Christ on the Hill* (1898), and the posthumous *Pasiteles the Elder and other Poems*. His most important work was done as an art critic and historian. Much of his work on art was contributed to the *Dictionary of National Biography*, and to periodicals. Separate works are: *The Italian Pre-Raphaelites* (1887), *The Earlier English Water-Colour Painters* (1890 and 1897), *In the National Gallery* (1895) and *British Contemporary Artists* (1899).

MONKSWELL, ROBERT PORRETT COLLIER, 1st BARON (1817–1886), English judge, was born at Plymouth, on June 21, 1817, the son of a merchant. He was educated at Oxford, was called to the bar in 1843, and went the western circuit. He obtained a high reputation by his successful defence of Brazilian pirates in 1845; the conviction was quashed on appeal on a point of law which the judge had refused to reserve. He was elected member of parliament for Plymouth in the Liberal interest in 1852, and in 1859 was appointed counsel to the admiralty and judge-advocate to the fleet. In this capacity he gave in 1862 an opinion in favour of detaining the Confederate rams building in the Mersey, which would have saved his country much money and much credit if it had been acted upon. In 1863 he became solicitor-general, and in 1868 attorney-general, and in 1869 successfully passed a bankruptcy bill. In 1871 he was appointed by Mr. Gladstone one of four new judges upon the judicial committee of the privy council, although it was expressly provided by the act creating these offices that none of them should be filled by a law-officer of the Crown. This prohibition was evaded by making Collier a judge of common pleas, and transferring him after a few days to the privy council. He received a peerage in 1885 and died on Nov. 3, 1886.

MONMOUTH, JAMES SCOTT, DUKE OF (1649–1685), leader of an abortive insurrection against James II. in 1685, was the son of Lucy Walters, who became the mistress of Charles II. during his exile at The Hague. He was born at Rotterdam on April 9, 1649. Charles always recognized him as his son, and lavished on him an almost doting affection. Until the Restoration he was placed under the care of Lord Crofts, by whose name he was known. In July 1662 he was sent for by Charles, and at thirteen came under the protection of Lady Castlemaine. No formal acknowledgement of his relation to the king was made until James's betrothal to Anne Scott, countess of Buccleuch, whom he married in 1665. During 1663 he was made duke of Orkney, duke of Monmouth and knight of the Garter, and on his marriage he and his wife were created duke and duchess of Buccleuch, and he took the surname of Scott. In 1670, on the death of Monk, he was made captain-general of the king's forces. Monmouth was now becoming a person of political importance. The anti-popery spirit was rapidly turning to frenzy, and the succession of James a probability and a terror. Charles was urged to legitimize Monmouth by a declaration of his marriage with Lucy Walters. Every attempt was made, especially by Shaftesbury, to accustom people to this idea, and his position was emphasized by James's second marriage, with the Catholic princess Mary of Modena. From this time his popular title was "the Protestant duke." In 1674 he was made "commander-in-chief";

and at Shaftesbury's instance was placed in command of the army employed in 1675 against the Scottish Covenanters, and was present at Bothwell Bridge (June 22, 1679). In 1678, when Charles was driven into war with Louis, Monmouth took command of the English contingent.

In 1679 the king fell ill, and the dangers of a disputed succession became apparent. The party opposed to Monmouth, or rather to Shaftesbury, prevailed upon Charles to consent to the return of his brother, James, from Brussels. When, after the king's recovery, James went back to Brussels, he received a promise that Monmouth too should leave the country. Accordingly, in Sept. 1679, the latter repaired to Utrecht, but he secretly returned to London two months later, and, as the champion of Protestantism, was well received. The king appeared to be greatly incensed, deprived him of his offices, and ordered him to leave the kingdom at once. This he refused to do, and henceforth was merely forbidden to appear at court.

It was at this time that the exclusionists, who, in the absence of parliament were deprived of their best basis for agitation, developed the system of petitioning. So successfully was this answered by the "abhorrers" that Charles, feeling the ground safer under him, recalled James to London—a step immediately followed by the resignation of the chief Whigs in the council.

Once more, an attempt was made to establish Monmouth's claims, but Charles again publicly declared that he had never been married but to the queen. Monmouth now went to the west of England, visiting the chief members of the country party, and gaining popularity among the people. When the right of James to the succession was again formally acknowledged by Charles in 1680, Monmouth threw himself vehemently into the plans of the exclusionists, speaking and voting for exclusion in the House of Lords. In 1681 the parliament passed a series of resolutions of extreme violence, of which one was that Monmouth should be restored to all his offices and commands; and when Charles summoned a fresh parliament to meet at Oxford the leaders of the exclusionists went thither with troops. Not until the dissolution of this last parliament, in March 1681, did the weakness of Monmouth's cause appear. The deep-seated respect for legitimate descent asserted itself, and a great reaction took place. In November Dryden published *Absalom and Achitophel.* Shaftesbury was attacked, and Monmouth himself did not escape insult in the street and from the pulpit. When he went, in 1682, on a second progress through the western and north-western counties his proceedings were narrowly watched, and he was arrested at Stafford. He was released on bail, and in February 1683, after the death of Shaftesbury, he openly broke the implied conditions of his bail by a third visit to Chichester on pretence of hunting.

The Rye House plot gave an excuse for arresting the Whig leaders; Russell and Sidney were judicially murdered; Monmouth retired to Toddington, and was left untouched. By two submissive letters, he reconciled himself with the help of Halifax both to the king and to James, though he had the humiliation of seeing his confessions and declarations of penitence published in the *Gazette.* His partial return to favour raised the hopes of his partisans; to check these, Algernon Sidney was executed. Monmouth was now subpoenaed to give evidence at the trial of young Hampden. To escape from the difficulty he fled to Holland, probably with Charles's connivance, and though he visited England in Nov. 1684, it is doubtful whether he ever again saw the king. The quiet accession of James II. soon brought Monmouth to the crisis of his fate. Within two months of Charles's death he had yielded to the impetuosity of Argyll and other exiles and to vague invitations from England.

DEFEAT AND CAPTURE

On the 2nd of May Argyll sailed with three ships to raise the west of Scotland; and three weeks later, with a following of only eighty-two persons—of whom Lord Grey, Fletcher of Saltoun, Wade, and Ferguson, the author of the *Appeal from the Country to the City,* were the chief—Monmouth himself set out for the west of England, the stronghold of Protestant dissent. He gained little sympathy, but soon collected an undisciplined body of some 1,500 men, with whom he seized Axminster, and entered Taunton. Meanwhile parliament had declared it treason to assert Monmouth's legitimacy, or his title to the crown; a reward of £5,000 was offered for him dead or alive, and an act of attainder was passed in unusual haste. Troops had been hurriedly sent to meet him, and when he reached Bridgwater Albemarle was already in his rear. From Bridgwater the army marched through Glastonbury to attack Bristol, into which Lord Feversham had hastily thrown a regiment of foot-guards. The attempt miscarried; and, after summoning Bath in vain, Monmouth, with a disordered force, began his retrograde march through Philips Norton and Frome, continually harassed by Feversham's soldiers. At the latter place he heard of Argyll's total rout in the western Highlands. On July the 5th, Feversham entered Sedgemoor in pursuit; Monmouth the same night attempted a surprise, but his troops were hopelessly routed. He himself, with Grey and a few others, fled over the Mendip Hills to the New Forest, hoping to escape by sea, but he was captured close to Ringwood in Hampshire on the 8th.

On the day of his capture Monmouth wrote to James in terms of the most unmanly contrition, ascribing his wrong-doings to the action of others, and imploring an interview. This was granted on the 13th and after another imploring letter to the king, he offered, as the last hope, to become a Roman Catholic; this might have proved successful, but the priests sent by James to ascertain his sincerity declared that he cared only for his life and not for his soul.

He met his death at the scaffold on July 15, 1685, with calmness and dignity. In a signed paper he expressed sorrow for having assumed the royal style, and at the last moment confessed that Charles had denied to him privately, as he had publicly, that he was ever married to Lucy Walters.

See G. Roberts, *Life, Progresses, and Rebellion of James, Duke of Monmouth* (2 vols. 1844), the article in the *Dict. Nat. Biog.* and general bibliography given in *Camb. Mediaeval Hist.* (vol. 5, chaps. 8 and 9, 1908).

MONMOUTH, ROBERT CAREY, 1ST EARL OF (*c.* 1560–1639), youngest son of Henry Carey, 1st Baron Hunsdon, chamberlain, and first cousin of Queen Elizabeth. In 1587 he joined in the attempt to relieve Sluys, in 1588 served as a volunteer against the Spanish expedition, and commanded a regiment in Essex's expedition to Normandy in 1591, taking part in the siege of Rouen. He was knighted by Essex the same year for having by his intercession with the queen procured his recall. In the parliaments of 1586 and 1588 he represented Morpeth; in that of 1593, Callington; and in those of 1596 and 1601, Northumberland. He succeeded to his father's appointment of lord warden of the marches in 1596, which he held till 1598. In March 1603 he witnessed the queen's last illness, which he described in his *Memoirs.* Two years later, he was made governor of Prince Charles, in 1611 his master of the robes, in 1617 his chamberlain, and in 1622 was created Baron Carey of Leppington. In 1623 he followed Charles to Spain, and after the latter's succession to the throne he was created earl of Monmouth in 1626. He died on April 12, 1639.

His *Memoirs* were published first by the earl of Cork and Orrery in 1759, a new edition, annotated by Sir Walter Scott, being printed in 1808.

MONMOUTH (Welsh *Mynwy*), municipal borough, and county town of Monmouthshire, England, 18 m. S. of Hereford, on the G.W. railway. Pop. (1931) 4,731. It is situated at the confluence of the Wye and the Monnow and is almost surrounded by hills. Monmouth (*Monemuta*) was possibly a fort from Roman times. Situated between Severn and Wye its strategic importance was early recognized by the Saxons, while in later years it played a leading part in Welsh border warfare. At the time of Domesday the castle was in the custody of William Fitz Baderon. Henry III. granted it to his son Edmund Crouchback, through whose descendants both borough and castle passed into the duchy of Lancaster. Since the 18th century the dukes of Beaufort have been lords of the borough.

Portions of the town walls remain, and there is an old gateway on the Monnow bridge; but there are only insignificant ruins of the castle, originally a Saxon fortress. The principal buildings

include the churches of St. Mary on an ancient site, and the chapel of St. Thomas, a late Norman structure, and the free grammar-school, founded in 1614.

Monmouth was a borough by prescription as early as 1256, and was governed by a mayor in 1461, but was not incorporated until 1550. This charter was confirmed in 1558, 1606 and 1666. By the act of 1535–36 Monmouth, as county town, obtained representation in parliament; it is now part of one of the county divisions. Wednesday and Saturday markets were confirmed to Monmouth in 1550. Since the 18th century it has been a quiet market town deriving some prosperity from the rise of the adjoining industrial regions as well as an annual three-days' fair.

MONMOUTH, a city of western Illinois, U.S.A., 56 m. S. of Rock Island and 18 m. from the Mississippi river; the county seat of Warren county. It is on Federal highway 34, and is served by the Burlington Route, the Minneapolis and St. Louis, and the Rock Island Southern railways. Pop. (1920) 8,116 (88% native white) and was 8,666 by the Federal census of 1930. It has large potteries and other manufacturing industries; ships several thousand carloads of cattle and hogs to Chicago every year; and is the seat of Monmouth college (United Presbyterian), opened as an academy in 1853, as a college in 1856. Monmouth was settled in 1824, incorporated as a village in 1836 and chartered as a city in 1852.

MONMOUTH COURT HOUSE, BATTLE OF. The battle of Monmouth Court House was fought (June 28, 1778) between the Americans under Gen. Washington and the British commanded by Sir Henry Clinton, who having evacuated Philadelphia (June 18) was marching through New Jersey to Sandy Hook. Washington had decided that for his country's honour and his own reputation he must strike a vigorous blow at the retreating enemy even at the risk of bringing on a general engagement, and ordered Charles Lee with the advanced guard to attack the British rear (June 28), promising to support him with the main body of the army. Lee had claimed this command, as the senior major-general in the army, though it had been originally assigned to Lafayette, and Washington now added to it two brigades, bringing it up to a strength of about 5,000. But Lee had no intention of carrying out the spirit of his orders. An ex-officer of the British army, who had seen much service in the Seven Years' War, he believed the Continental troops to be no match for British regulars in the field and held it madness to risk a pitched battle before the arrival of French troops in America. He contemplated nothing more than a forced reconnaissance. Clinton after a 40 hours' halt at Monmouth Court House (now Freehold) made an early start (June 28). His baggage train of 1,500 wagons led the way under escort of Knyphausen's German division, and Cornwallis's British division formed the rear-guard.

When Lee approached Monmouth he found only a small covering force there. He was executing an elaborate manoeuvre to envelop it, when Cornwallis's division appeared. Clinton had ordered his lieutenant to turn back and strike hard at the attacking force, in order to prevent any attempt to harass his trains. Instead of fighting a delaying action with a force not much stronger than his own on ground well adapted for the purpose and gaining time for Washington to come up, Lee allowed his troops to retreat. He had ordered his right to fall back, but gave no orders to the rest, and they finding themselves in danger of being cut off, also retired. Lee made little effort to check the somewhat disorderly retreat and sent Washington no warning that he was retiring. When the commander-in-chief came up, he was surprised and indignant, and hastened to form a line of battle with the divisions of Greene and Alexander (called by the Americans Lord Stirling) on the right and left, while part of Lee's force rallied under Wayne and checked the pursuit of the British cavalry. Cornwallis brought up his infantry and endeavoured to dislodge Washington but without success. The fiercest fighting was in front of the centre behind a hedge fence held by the heroic Wayne, who repulsed three fierce assaults of British grenadiers. Towards evening Cornwallis fell back. Washington sent forward three brigades to renew the battle, but darkness forestalled them. During the night Cornwallis withdrew, undetected by the American outposts, and overtook Knyphausen near Middletown, where the high ground secured them from further attack. Washington finding the enemy gone attempted no pursuit and presently marched to the Hudson to join Gen. Gates, whilst Clinton's army was conveyed by transports from Sandy Hook to New York. The two combatants resumed the positions, which they had held two years before.

Of the two armies Clinton's seems to have been a little the larger—about 17,000 to 14,000. But not much more than half of the British army was actually engaged. Washington returned 360 casualties and Clinton 358, but the Americans claimed to have buried 249 British dead on the battlefield. Owing to the intense heat nearly 100 men in the two armies died of sheer fatigue. A court-martial suspended Lee from any command in the American armies for twelve months. Subsequently he was dismissed from the American service on account of his attacks upon Washington. In 1860 Lee's letter to Gen. Howe, written when he was a prisoner in British hands, suggesting a plan of campaign for Howe's forces, came to light, and later writers have added to the charge of incompetence and insubordination against Lee that of deliberate treachery. The evidence seems in favour of acquitting Lee of any worse crime than disloyalty to his commander.

See W. S. Stryker, *The Battle of Monmouth* (Princeton, 1927).

MONMOUTHSHIRE, a western border county of England, bounded east by Gloucestershire, north-east by Herefordshire north-west by Brecknock, west and south-west by Glamorganshire (Wales), and south by the estuary of the river Severn. The county falls into two natural regions:—the basin of the Usk (after that river emerges from the gap between the Brecon Beacons, 2,907 ft., and the Black mts., 2,624 ft.), which forms the north-eastern and central portions of the county, and the basins of the river Rhymney and the river Ebbw which drain the south-east slopes of the Brecon Beacons, *i.e.,* the eastern end of the south Wales coal-field. The river Monnow forms the north-east boundary of the county, but its upper waters include a section of the Black mts., within the county boundary on the north side. After the junction of the Monnow with the Wye at Monmouth, the main river becomes the eastern boundary; the upper and middle river Rhymney form its western border. The Monnow, and the Wye as far as Tintern, pass over Old Red Sandstone rocks (a great series of red marls, sandstone and concretionary limestones), which occupy the north-east and central parts of the county, grits and conglomerates of the highest beds giving rise to bold escarpments and lofty plateaux (*e.g.,* The Sugar Loaf, 1,955 ft., Skirrid Fawr 1,596 ft., and Blorenge, 1,838 ft., which almost encircle the town of Abergavenny).

West of the town of Usk, the Old Red Sandstone plain is interrupted by an extensive anticline of older Silurian strata (Wenlock shale and limestone and Ludlow beds), a small inlier of the same rocks appearing at Rhymney near Cardiff. The Rhymney (down to Caerphilly), and the Ebbw (with the Sirhowy and other tributaries) which joins the Usk below Newport, are parallel consequent streams draining the coal-field, which here consists of a series of north-north-west to south-south-east valleys, separated by high ridges of Pennant grit, and related to lines of faulting that are much later than the foldings of the coal-field. These valleys are deep and narrow, and often of U-shaped transverse profile, due to scouring by glaciers from the Brecon Beacons. The Carboniferous limestone, millstone grit, and coal measures (lower coal series, Pennant sandstone and upper coal series) dip westward and succeed each other from east to west. The Coal Measures abound in coal-seams and ironstone and their valleys, densely populated with people formerly occupying higher pastoral districts, now forsaken, give rise to acute social and economic problems. Around the eastern edge of the coal-field a narrow rim of Carboniferous limestone occurs, and is crossed by a western tributary of the Usk at Pontypool. Very striking land forms are seen in the valley of the Wye between Tintern and Chepstow, where Carboniferous limestone again appears on the western rim of the outlying Forest of Dean coal-field (Glos.). Rhaetic and Lias limestones and shales outcrop at Llanwern and

Goldcliff, near Newport. Glacial gravel and boulder clay are found in the valleys, and a broad tract of alluvium borders the Bristol channel from Rhymney to Portskewet, forming a lowland way through Monmouthshire to the Vale of Glamorgan, part of the plain of Gwent.

History and Early Settlement.—Monmouthshire in early times was heavily forested and formed part of the difficult country of the lower Severn. There are evidences of the use of the route to the west (via the south Wales coastal plain) in the Bronze age; finds of flat axes and socketed celts being important in the southern section of the county. The westward route was used by the Romans, who built Caerwent and Caerleon (*q.v.*), the latter of which performed a service similar to that performed by Chester in the north, guarding the coastal route into Wales.

Monmouthshire, at the time of the Heptarchy, formed the Welsh kingdom of Gwent, and no permanent English settlement was effected in the district until close upon the middle of the 11th century. The incursions of the West Saxons began in the 7th century, and Brochmael and Fermael, kings of Gwent, acknowledged Alfred as their lord. In the 9th and 10th centuries the district was frequently harried by the Danes, who in 915, under Ohter and Hwald, sailed round Wessex and Cornwall to the Severn, plundered the banks of the Wye and took prisoner the bishop of Llandaff. In 926 Aethelstan met the kings of the north Britons at Hereford and fixed the Wye as the limit of their territory. In 976 the Danes destroyed Caerleon, at this time the chief town of the district. The early 11th century was taken up with interminable contests between the Welsh princes for the succession in south Wales, and the Welsh Chronicle relates that in 1047 the whole of South Wales lay waste, and in 1049, Griffith, the king of South Wales, assisted Irish pirates in plundering. In 1065 Harold conquered the district between the lower Wye and the Usk.

After the Conquest, this district was bestowed on William Fitz Osborne, earl of Hereford, who built Monmouth castle, and continued the line of defence against the Welsh frontier along the Wye, while a second line of fortifications along the Usk valley marked the continued advance of the Normans, who by 1085 had subjugated almost the whole of Gwent. The lordship of Overwent fell to Hamelin de Baladun, who founded the castle and priory of Abergavenny, and from him passed to Brian Fitz Count and later to Walter Fitz Miles, earl of Hereford. The lordship of Netherwent remained for many centuries with the Clare family. Penhow castle was a stronghold of the family of St. Maur or Seymour, from whom are descended the present dukes of Somerset, and Grosmont and Skenfrith castles of the family of Braose. Gwent still ranked as Welsh territory at the time of Domesday, but the town of Monmouth, the castle of Caerleon, and the district of Archenfeld, are assessed under Herefordshire, and the three hardwicks of Llanwern, Portskewet and Dinam under Gloucestershire. The Norman lords of the present county held their lands "per baroniam," so that the king's writ did not run in them, and the lives and property of the poorer inhabitants were entirely at the mercy of these lords marchers. The county still exhibits remains of 25 Norman castles. The province of Gwent was formerly divided into four cantrefs, each comprising several commotes. Cantref Uwchcoed, or Upper Gwent, comprised the commotes of Erging and Ewyas, now principally in Herefordshire, and the greater part of the present hundreds of Skenfrith, Abergavenny and Usk; Cantref Iscoed, or Lower or Nether Gwent, comprised the present hundred of Raglan and parts of Caldecot and Usk; Cantref Gwentlwg comprised the present hundred of Wentlwg; while the fourth cantref, Cantref Coch, now forms the forest of Dean in Gloucestershire. Leland, (16th century) describes Gwent as comprising the three divisions of low, middle and high "Venteland," and at this period it included 24 lordship marches, each governed by its own ancient laws and customs, and ruled by its own lord. Under the act of 1536 for the abolition of the marches, these 24 lordships were united to form a shire with Monmouth as the shire town, and the sheriff's court held alternately at Monmouth and Newport. The shire was divided into six hundreds—Abergavenny, Caldecote, Raglan, Skenfrith, Usk and Wentlwg—the bounds being subsequently ratified by act of parliament of 1542–43. No sheriffs were appointed until 1541, and the legal authority of the lords marchers was not finally abolished until 1689. The act of 1536 did not expressly separate the county from Wales, and it was only gradually that Monmouthshire came to be regarded as an English county, being included in the Oxford circuit for the first time in the reign of Charles II.

Ecclesiastically Monmouthshire has been almost entirely in the diocese of Llandaff since its foundation in the 6th century. Monmouth was in the diocese of Hereford, and a few parishes formed part of the diocese of St. Davids until 1836, when the whole county was placed under the bishop of Llandaff. It contains, wholly or in part, 134 ecclesiastical parishes.

Architecture.—Of Norman fortresses, the more interesting are: Caldicot, the seat of the De Bohuns, with a round keep of the 13th century, gatehouse and other portions, still partly inhabited; Chepstow, one of the finest examples of the Norman fortress extant, in an imposing situation on a cliff above the Wye; Newport, Abergavenny, the gateway and hall of Grosmont, once the residence of the dukes of Lancaster; and Usk castle, rebuilt by the Clares in the time of Edward IV. Raglan castle, begun in the reign of Henry V., is a very extensive ruin, still in good preservation. Charles I. resided in it after the battle of Naseby, and in 1646 it was delivered up to the parliamentary forces after a stubborn resistance of ten weeks against Col. Morgan and Gen. Fairfax.

At the Reformation Monmouth possessed two hospitals and 15 other religious houses; of these only Llanthony abbey and Tintern abbey (both Cistercian) are important. Llanthony abbey in the Black mts. was founded by William de Lacy in 1103, and the church, dating from about 1200, is one of the earliest examples in England of the Pointed style. The ruins consist of portions of the nave, transept, central tower and choir. Tintern abbey (*q.v.*), founded by Walter de Clare in 1131, occupies a position of great beauty on the Wye, and is amongst the finest monastic ruins in England. Churches worthy of mention are Abergavenny, belonging to a Benedictine priory, and containing a number of old tombs; Chepstow, partly Norman, and possessing a richly moulded doorway; St. Woolos' church, Newport, also Norman; the Norman chapel of St. Thomas, Monmouth, Christchurch, principally Norman; Mathern, Early English, with a tablet to Tewdrig, king of Gwent in the 6th century; and Usk, formerly attached to a Benedictine priory.

Agriculture.—Along the Severn shore the soil is deep and loamy, and admirably suited for the growth of trees. The most fertile land is that resting on the red sandstone, especially along the banks of the Usk, where wheat of fine quality is raised. In the mountainous regions more attention is paid to the grazing than to the raising of crops. There are a considerable number of dairy farms, but sheep-farming is much more largely followed. Only about seven-tenths of the total area of the county is under cultivation. There is a large extent of hill pasture, and a considerable acreage under orchards. The river fisheries of Monmouthshire have been famed from early times, Caerleon with seven fisheries in the Wye and the Usk being mentioned in Domesday.

Mining.—The coal-mines and iron-works which Monmouthshire shares with south Wales are very important. The industry of coal-mining is said to date from the time of Edward I., but the industry lapsed until the construction of the Blaenavon-Newport canal (1792–95). In 1740 Monmouthshire contained only two furnaces, making 900 tons annually. In 1790 three new furnaces were constructed at Blaenavon, and since then the industry has steadily grown. These, in order from east to west, with the principal townships in each are as follows:—Afon Lwyd (Panteg, Pontypool, Abersychan and Blaenavon); Ebbw Fach (Abertillery, Nantyglo and Blaina), joining the Ebbw (Risca, Ebbw Vale); Sirhowy (Bedwellty and Tredegar); Rhymney (New Tredegar and Rhymney). Besides coal, considerable quantities of fire-clay and some iron are raised.

Communications.—The county is served by the G.W. rail-

way. Main lines run from Cardiff (Glam.) north through Newport, Pontypool and Abergavenny to Hereford; south-west along the Severn estuary from Gloucester to Chepstow, Newport (with branch to Caerphilly) and Cardiff; across the centre of the county from Monmouth to Usk, Pontypool and on to Pontypridd (Glam.) All these link up with various valley routes. A line of the L.M.S. railway crosses the north of the county from Abergavenny to Merthyr (Glam.) with branches to Blaenavon and down the Sirhowy. The Crumlin canal from the Ebbw valley, and the Monmouthshire canal from Pontypool converge upon Newport, which is the principal port in the county. The Brecon canal runs north from Pontypool into the valley of the Usk.

The area of the administrative county and associated county borough is 349,569 acres; pop. (1931) 434,821. The county comprises six hundreds. Municipal boroughs are Abergavenny, Monmouth, and Newport, a county borough. Monmouthshire is in the Oxford circuit, and assizes are held at Monmouth, and it has one court of quarter sessions. The boroughs of Monmouth and Newport have commissions of the peace, but no separate court of quarter sessions. The parliamentary divisions are Abertillery, Bedwellty, Ebbw Vale, Monmouth and Pontypool, each returning one member; and the parliamentary borough of Newport returns one member. By the act of 1536 two knights were to be returned for the shire and one burgess for the borough of Monmouth, but the first returns for the county were made in 1547 and for the borough in 1553.

MONNIKENDAM, a fishing village of Holland, in the province of North Holland, on an inlet of the Zuider Zee known as the Gouw Zee, 12 m. N.N.E. of Amsterdam. Pop. (1926), 2,537. It was once a commercial town but now it is a tourist centre. Among the notable buildings are the weigh-house (17th century), the bell-tower (1591), formerly attached to the town-hall before this was destroyed in the 18th century, and the church of St. Nicholas, mentioned in a document of 1356, but not completed until the beginning of the 15th century. It contains some carvings and many old tombs.

MONO or **MONACHI,** two Shoshonean Indian groups in central California, of the same dialectic division of that family as the Northern Paiute of Nevada and the Bannock of Idaho. Mono is Spanish for monkey, but Monachi is the term for them among the neighbouring Yokuts. The western Mono, in the pine belt of the Sierra Nevada, are acculturated to the Yokuts below them; the eastern Mono, of Mono and Owens valley across the crest, locally called Paiute, are more similar to their congeners of the Great Basin. The Mono have suffered less from Caucasian contacts than any California tribe, and therefore survive as the most populous native group in the state, there being 1,400 in 1910. The western Mono form a distinct physical type, with narrow heads.

MONOCHORD, an instrument having a single string, used by the ancient Greeks for tuning purposes and for measuring the scale arithmetically. A movable bridge was so contrived as to slide along over the string and stop it at any point.

MONOCOTYLEDONS: *see* ANGIOSPERMS.

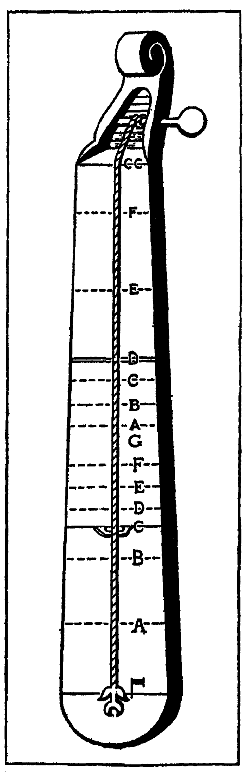
MONOD, ADOLPHE (1802–1856), French Protestant divine, was born on Jan. 21, 1802, in Copenhagen, and was educated at Paris and Geneva. He began his life-work in 1825 as founder and pastor of a Protestant church in Naples, whence he removed in 1827 to Lyons. Here his evangelical preaching, and especially his sermon on the duties of communicants led to his deposition. In 1836 he became professor in the Theological college of Montauban, removing in 1847 to Paris as preacher at the Oratoire. He died on April 6, 1856. Monod was undoubtedly the foremost Protestant preacher of 19th century France.

His chief works are *Sermons* (1844, Eng. trans. 1849); *La Femme* (1848, Eng. trans. 1851) and *S. Paul* (1851, Eng. trans. 1853). Extracts from his correspondence appeared at Paris (1885–1902). *See* A. Richardot, *A. Monod considéré comme prédicateur* (Strasbourg, 1863) and P. Stapfer, *La grande Prédication chrétienne en France* (1898).

FRÉDÉRIC MONOD (1794–1863), his brother, was born at Monnaz, Switzerland on May 17, 1794, and died at Paris on Dec. 30, 1863. Ordained at Geneva in 1818, he spent most of his life in Paris, where with Count Gasparin he founded in 1849 the Union of the Evangelical Churches of France.

MONOD, GABRIEL (1844–1912), French historian, was born at Havre on March 7, 1844, and died at Versailles on April 10, 1912. He studied at the École Normale Supérieure, Paris, and at Göttingen and Berlin before he began to lecture at the École Normale. He wrote a number of important studies on mediaeval history and a *Bibliographie de l'histoire de France* (1888), but his greatest work was done as a teacher. His pupils dedicated to him a volume of *Études d'histoire du moyen âge* (1896). Monod founded the *Revue Historique.*

MONODELPHIA, a term applied by De Blainville in 1816 and 1834 to the highest of his three main subdivisions (subclasses) of the class Mammalia, which embraced all the mammals except the monotremes and marsupials. The name, meaning "single uterus" was given in allusion to the fact that with certain exceptions the lower parts of the right and left ducts that lead down from the ovaries are united into a single womb. This most advanced condition, called "uterus simplex," is found in man, primates generally and many bats. When the fusion of the right and left ducts is complete only at the lower end, the womb being distinctly forked, the term "uterus bicornis" is applied, as in ungulates and insectivores, and when there are distinct traces of the median partition separating the right and left halves, the condition is called "uterus bipartitus" as in carnivores. An alternative title for the group is Placentalia. Eutheria of Huxley is frequently, but incorrectly, used as the equivalent of Monodelphia.



FROM HENRY BODDINGTON, CATALOGUE OF MUSICAL INSTRUMENTS

THE MONOCHORD, AN INSTRUMENT INVENTED BY THE ANCIENT GREEKS TO INVESTIGATE THE MATHEMATICAL RELATIONS OF MUSICAL INTERVALS

MONOGENISTS, the term applied to those anthropologists who claim that all mankind is descended from one original stock (μόνος, single, and γένος, race), and even from a single pair; while polygenists (πολύς, many) contend for a multiple ancestry. Aristotle and Vitruvius saw in climate and environment the natural cause of racial differences, influences far slighter in amount and slower in operation than was supposed. But although the reality of some such modification is not disputed, a remarkable permanence of type is displayed by races long after migration to climates extremely different from that of their former homes. Physically different races, such as the Bushmen and the pure negroid types in Africa, show no signs of approximation under the influence of the same climate; while the coast tribes of Tierra del Fuego and forest tribes of tropical Brazil continue to resemble each other, in spite of extreme differences of climate and food. Darwin is moderate in his estimation of the changes produced on races of man by climate and mode of life within the range of history (*Descent of Man,* pt. i. chs. 4 and 7). A great difficulty of the monogenist theory lay in the shortness of the chronology with which it was formerly associated. It is now recognized (*see* MAN, EVOLUTION OF) that man has existed during a vast period of time.

A. R. Wallace suggested that the remotely ancient representa-

tives of the human race were in their wild state much more plastic than now to external nature. (*Contributions to the Theory of Natural Selection*, p. 319.)

The polygenist theory is not dead. An interesting problem is raised by the discovery that the composition of the blood is transmitted on Mendelian principles, and that there are at least two main varieties of blood. Further advances in physiology may help towards a solution of the question. The multiplicity of languages has been cited as evidence of polygenesis, but language is a social factor—part of the cultural acquisition of mankind—and efforts have been made to prove the common descent of all languages though links are missing and the data allow of other explanations.

MONOGRAM, originally a cipher consisting of a single letter, now a design or mark consisting of two or more letters intertwined together. The letters thus interlaced may be either all the letters of a name or the initial letters of the Christian and surnames of a person for use upon note-paper, seals, etc. Many of the early Greek and Roman coins bear the monograms of rulers for whom, or the towns in which, they were struck. The late Latin and Greek words were first applied to the signatures, which took this form, of the emperors of the eastern empire. The signatures of the Frankish kings also took the form of a monogram. The most famous of monograms is that known as the "Sacred Monogram," formed by the conjunction of the two initial letters of χριστός, Christ. The most usual form of this is the symbol ☧ and sometimes the α (alpha) and ω (omega) of the Apocalypse were placed on each side of it. The symbol was incorporated in the *Labarum* (*q.v.*) when the imperial standard was christianized. The interlaced I.H.S. (also called the "Sacred Monogram") apparently possesses no great antiquity; it is said to have been the creation of St. Bernard of Siena in the middle of the 15th century. Monograms or ciphers were often used by the early printers as devices, and are of importance in fixing the identity of early printed books. Similar devices have been used by painters and engravers. The middle ages were, indeed, extremely prolific in the invention of ciphers alike for ecclesiastical, artistic and commercial use. Every great personage, every possessor of fine taste, every artist, had his monogram. The mason's mark also was, in effect, a cipher. As the merchant had as a rule neither right nor authority to employ heraldic emblems, he, therefore, fell back upon plain simple letters arranged very much in monogram form. These "merchants' marks" generally took the form of a monogram of the owner's initials together with a private device. They nearly always contain a cross, either as a protection against storms or other catastrophes, or as a Christian mark to distinguish their goods from Mohammedan traders in the East. There is a fine example of a 16th century gold ring with a merchant's mark in the British Museum. One of the most famous of secular monograms is the interlaced "H.D." of Henri II. and Diane de Poitiers. Upon every building which that king erected it was sown profusely; it was stamped upon the bindings in the royal library, together with the bow, the quiver and the interlocked crescents of Diana. Henri IV. devised a punning cipher for his mistress Gabrielle d'Estrées, the surname being represented by a capital S. with a *trait* or stroke through it.

See Du Cange, *Glossarium* (*s.v. Monogramma*), with plates giving examples of the monograms of early popes, the emperors of the Western Empire, and of other kings.

MONOLOGUE, a passage in a drama in which a personage speaks unconsciously aloud, either alone on the stage or with others keeping silent. The tragedies of the 17th and 18th centuries greatly affected the monologue, which has always, however, been liable to ridicule. There is something of a lyrical character about the monologue in verse; and many of the examples in the tragedies of Corneille are nothing more or less than odes or cantatas. The monologues of Shakespeare and Racine have a more dramatic character. The French critics record as striking examples that of Figaro in Beaumarchais' *Le Mariage de Figaro* and the 160 lines of Charles V. in Victor Hugo's *Hernani*. In the Elizabethan drama, the popularity of Kyd's *Spanish Tragedy*, in which Hieronymo spouts interminably, set a fashion for ranting monologues, which are very frequent in Marlowe and others. After 1600 the practice was much reduced, but it returned in exaggerated form after the Reformation to fall once more into deserved contempt.

MONOMETALLISM, a term applied to a currency system in which one metal only is used as a standard. (*See* MONEY; BIMETALLISM.)

MONOMOTAPA. In old maps of south-east Africa, derived originally from Portuguese and from Dutch sources, an extensive region on the Çuama or Zambezi and to the south of it is styled *regnum monomotapae*. The precise character of the kingdom has been the subject of much discussion, and some modern historians relegate the monomotapa to the realm of myth. But such scepticism is unjustifiable since all Portuguese writers from the beginning of the 16th century onwards reiterated the assertion that there was a powerful rule known far and wide by that title.

The word "monomotapa" is of Bantu origin and has been variously interpreted. Father J. Torrend, *Comparative Grammar of the South African Bantu Languages* (p. 101) renders it "Lord of the water-elephants," and remarks that the hippopotamus is even to the present day a sacred animal among the Karanga. The earliest recorded bearer of the name is Mokomba Menamotapam, mentioned by Diogo de Alcaçova in 1506 as father of the Kwesarimgo Menamotapam who ruled at that date over Vealanga, a kingdom that included Sofala. His capital was called Zumubany, an obvious corruption of the term "Zimbabwe," the residence of any important chief. Portuguese chroniclers not only refer to the territory and the people of the monomotapa as "Mocaranga" (*i.e.*, of the Karanga tribe), but explicitly assert that the "emperor" himself was a "Mocaranga." Consequently, he must have been a negro, and the Dominican who records the baptism of Dom Filippe by a friar of the order in the middle of the 17th century actually states that this "powerful king" was a black man ("com as carnes pretas"). This seems to controvert the assumption that there existed in southern Rhodesia a ruling caste of different racial origin from the general Bantu population.

It is difficult to arrive at an estimate of the extent of territory over which this great negro chief exercised direct or indirect control. The most extravagant theory is naturally that which was expressed by the Portuguese advocates in connection with the dispute as to the ownership of Delagoa Bay. The crown of Portugal based its case against England on the cession of territory contained in a well-known treaty with the monomotapa (1629), and stated that this monarch's dominions then extended nearly to the Cape of Good Hope. A more moderate and usual view is given by Diogo de Couto, who in 1616 speaks of "a dominion over all Kaffraria from the Cabo das Correntes to the great river Zambezi." Several 17th-century writers extend the "empire" to the north of the Zambezi, Bocarro giving it in all "a circumference of more than three hundred leagues." It was "divided among petty kings and other lords with fewer vassals who are called inkosis or fumos." According to these authors, however, including Dos Santos, the paramountcy of the monomotapa was impaired in the 17th century by a series of rebellions. His zimbabwe, wherever it may have been in earlier days, was now fixed near the Portuguese fort of Masapa, only a short distance south of the Zambezi. A Portuguese garrison was maintained in it, and the monarch himself from the year 1607 onwards was little more than a puppet who was generally baptized by the Dominicans with a Portuguese name.

MONONGAHELA, a city situated in Washington county, Pennsylvania, U.S.A., on the Monongahela river, 31 m. S. of Pittsburgh. It is served by the Pennsylvania and the Pittsburgh and Lake Erie railways. Pop. (1920) 8,688; and was 8,675 in 1930. It is surrounded by highly productive coal mines, and has glass works, paper mills, foundries and other manufacturing industries. A town was laid out here in 1792 by Joseph Parkinson. He named it Williamsport, but until its incorporation in 1833 it was commonly called Parkinson's Ferry. It was here that

the Whiskey Insurrection convention met on Aug. 14, 1794.

MONOPHYSITES, the name given to those who hold the doctrine that Christ had but *one* (μόνος) composite *nature* (φύσις) and especially to those who maintained this position in the great controversies of the 5th and 6th centuries. The synod of Chalcedon (*q.v.*) in 451, following the lines of Pope Leo I.'s famous letter, endeavoured to steer a middle course between the so-called Nestorian and Eutychian positions. But the followers of Cyril of Alexandria, and with them those of Eutyches, saw in the Chalcedon decree of two natures only another form of the "Nestorian" duality of persons in Christ, and rose everywhere in opposition. For a century they were a menace not only to the peace of the Church but to that of the empire.

During the period between the Council of Chalcedon and the death of Justinian, the movement on the whole gained in strength, especially in Egypt, and was the cause of civil disturbances in Jerusalem, Alexandria, Antioch, Constantinople and other centres in the East. Justinian himself in his later days adopted it (*see* below); but his successor, Justin II., took no action either way for six or seven years, and then instituted a quiet but thorough system of suppression, closing monophysite churches and imprisoning their bishops and priests.

We find two principal varieties of monophysitism. (*a*) Severus (bishop of Antioch 513) and his followers objected to Chalcedon only because it was an innovation; they fully acknowledged the distinctness of the two natures in Christ, insisting only that they became indissolubly united so that there was only one energy (*μία καινὴ θεανδρικὴ ἐνέργεια*) of Christ's will. Severus laid great stress on the human infirmities of Christ as proving that His body was like ours, created and corruptible; and some of his followers extended the argument to Christ's human soul, which they said was, like ours, limited in knowledge. (*b*) Julian, bishop of Halicarnassus, and his followers, held that Christ's body was so inseparably united with the Logos as not to be consubstantial with humanity; its natural attributes were so heightened as to make it sinless and incorruptible. Some even held that from the moment the Logos assumed the body the latter was *uncreated,* the human being transmuted into the divine nature; and the "adiaphorites" went still further, denying like Stephen Barsudaili, an Edessan abbot, all distinction of essence not even between the manhood and the Godhead in Christ, but between the divine and the human, and asserting that "all creatures are of the same essence with the Creator."

The disintegration caused by monophysitism largely facilitated the rapid and easy victory of Islam in Syria and Egypt. (*See* MONOTHELITES.)

MONOPLANE. An aeroplane with one pair of wings. Some of the earliest aeroplanes were of this type (*e.g.* the machines of

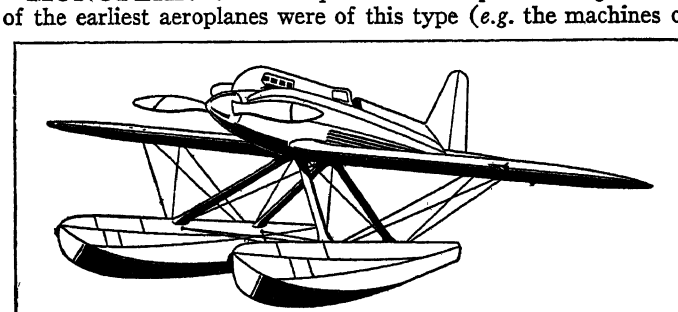

FIG. 1.—THE SUPERMARINE NAPIER MONOPLANE IN WHICH LIEUTENANT S.N. WEBSTER WON THE SCHNEIDER CUP IN 1927

Bleriot and Latham) but the structural advantage of the BIPLANE (*q.v.*) led to its preference by other pioneers (the Wrights, who were the first to fly, Farman, Cody and others). A monoplane is generally heavier and always less compact than the corresponding biplane. Monoplanes were little used during the World War, but the type has been widely adopted since by German, Dutch and American designers, though hardly at all in England. If the wing itself can be made thick enough to contain all the necessary supporting structure, an externally clean design results, and it is due mainly to the discovery of suitable thick wing sections in Germany that the type reappeared. Fig. 1 shows the Supermarine-Napier monoplane which won the Schneider cup in 1927 and fig. 2 the Ryan monoplane in which in May 1927 Captain (later

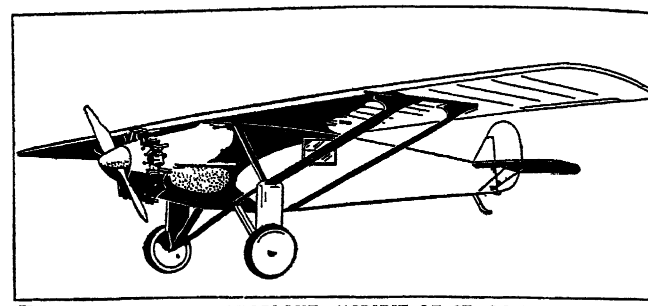

FIG. 2.—THE RYAN MONOPLANE, "SPIRIT OF ST. LOUIS," WHICH COL. LINDBERGH FLEW SOLO FROM NEW YORK TO PARIS IN 33½ HOURS

Col.) Lindbergh flew alone from New York to Paris in 33½ hours. (*See* also AEROPLANE, § 6 and 9.)

MONOPOLY. The term monopoly, in its early usage, was applied to grants from the Crown, to a favourite or as a reward for good service, of the exclusive right to manufacture or sell particular classes of goods. Not until the reign of Henry VIII. does much evidence appear of these grants in the case of either new inventions or familiar articles of trade. Elizabeth granted patents of monopoly so freely that the practice became a grave abuse, giving rise to serious complaints in the House of Commons, and to the suppression of many exclusive rights in 1601. In the first parliament of James I. a "committee of grievances" was appointed and again many monopoly patents were cancelled. Many more, however, were granted by the king, and there grew up a race of "purveyors" who made use of the privileges granted them under the great seal for various purposes of extortion. After the introduction of several bills, and several attempts by James to compromise the matter by orders in council and promises, the Statute of Monopolies was passed in 1624. This Statute made all monopolies illegal, except such as might be granted by parliament, or were in respect of new manufactures or inventions, or were exercised by civic corporations or companies and it would no doubt have greatly diminished the evils of monopoly had it not been for subsequent transgressions of the Act based in the main upon these excepting clauses. Under Charles I., the local monopoly of civic corporations began to be used as a cover for national monopolies. This was accomplished by the corporation obtaining from the sovereign a right of "superintendence" over the whole national production of the article, which in practice meant a strangle-hold upon rival producers. The grant of patent rights for new inventions was similarly abused by the according to the patentees of Crown rights of surveillance over all other producers of the commodity; while the title exercised by the Crown over all mines producing gold and silver was used as a basis for monopolistic control over tin, lead, and copper mines, of which the precious metals were an incidental by-product. In 1640, however, the Long Parliament declared most monopolies void, and the Bill of Rights ended, in 1689, the claim of the Crown to override the law.

In its modern usage the term monopoly is applied to the advantage accruing to any undertaking or associated group of undertakings which has the power, however acquired, of fixing the price of its goods or services in the knowledge that those who need them cannot get them in adequate measure elsewhere. Vestiges of the earlier usage remain in the monopoly conferred for a term of years under the patent and copyright laws; in the territorial monopolies accorded by Parliament to railway, gas, water, and electricity companies; in the monopoly exercised by the state in respect of postal, telephone and telegraph services; and in the partial monopoly which may occur where trading is permitted only under licence, as in the case of the sale of alcoholic liquors, wireless broadcasting, the plying of vehicles for public

hire, etc. These monopolies, however, are based on a genuine public interest.

Patent rights are conferred that an inventor may publicly disclose the details of his invention; parliamentary powers are required in order that duplication, inconvenience, and waste may not occur from two or more public utility services operating in the same area; and licences are required in order that certain traffic may be under limitation and control. State-accorded monopolies or quasi-monopolies are usually granted on conditions imposed in the interest of the revenue or the public—on the payment of licence or patent fees, the observance of a tariff scale, or the acceptance of the principle of limitation of profits.

Examples of monopolies are numerous. The village shop is "a monopoly" when there is no rival shop in the neighbourhood. When greyhound racing suddenly became popular, the breeders were able to demand pounds where six months before they would have been glad of shillings. The proprietors of estates near which a railway is driven, or over which an industrial population spreads, find themselves the holders of a commodity which cannot be multiplied and the beneficiaries of a demand for their property in the creation of which they have had no part. A monopoly may be due to the sheer excellence of the services rendered by particular concerns.

The merit or demerit of the monopoly created by deliberate intent is much more difficult to assess. The creation of some degree of monopoly is in some circumstances an essential factor in the suppression of wasteful competition and the intelligent conduct of an industry as one organic whole. That being so, monopoly may be a proper object of pursuit. The National Light Castings Association in its original rules explicitly stated its object to be that of "raising and keeping up the price to the buyer of goods and articles made and/or supplied by its members . . . by so controlling production that prices will rise naturally and inevitably, as they always must do when supply is brought into equilibrium with or is ever so little below demand." All British associations for the regulation of trade pursue, usually under some euphemism, the same object—that of obtaining a degree of monopolistic power by the limitation of competition; and American associations continue to seek lawful expedients by which production and price shall be steadied against the impacts of blind competition. The great consolidation which comes to terms with its great rival, or buys out a troublesome smaller competitor does so in order to secure a greater measure of monopoly. *See* TRUSTS.

Monopoly Power, 80%.—Complete monopoly is not essential to the exercise of monopolistic power. It has been asserted that any consolidation or association which covers 80% of the output of an industry can dictate the prices at which the remaining 20% shall sell its competing products, and so may be described as having an effective monopoly; but that formula cannot be applied indiscriminately, inasmuch as the limiting conditions of control vary greatly from industry to industry. The power over prices of the incomplete monopoly has been attributed to its power to regulate the greater part of the output of the industry, but this view is not tenable; its power over prices rests in fact upon the reluctance of the non-combine firm to incur the combine's aggressive hostility, coupled with a readiness to accept for its limited output the high prices ordained by the combine rather than strive after a larger output at a lower price of its own making. It should further be observed that the power of even a 100% monopoly to raise prices against the consumer is limited. The customer has his own recourses, varying much according to the particular commodity, of going without the article or of resorting to some substitute. The intelligent monopolist, on this score alone, will not raise prices to such an extent as to injure his own net revenues; and in practice he will guard against incurring public odium and possible action by the legislature. Also he must not forget that the knowledge of large profits will cause rivals to spring up, whose destruction will cost him some of his gains.

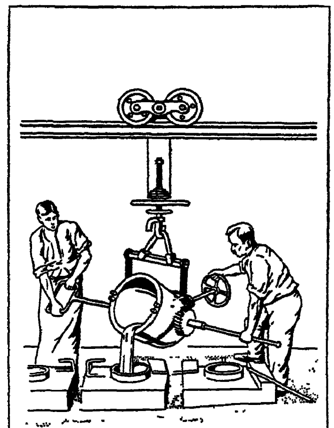
MONORAILS AND TELPHERS. Machines of the type usually known as *monorails* are installations which handle relatively light loads, *i.e.*, from 1 cwt. to 1 ton net, such a device is shown in fig. 1. The trolley can be combined with a lifting block which may be manually, mechanically or electrically operated. *Telphers* are on a similar principle but are always electrically driven. They are divided into *monorail telphers* and *bottom-flange telphers,* the latter being also called *transporters.* In the monorail type the machine travels on a "bulb-headed" or "bridge" rail, secured to the top of an I-beam; in the bottom-flange type the running wheels are duplicated and travel on both sides of the bottom flange of an I-beam. Monorails proper and bottom-flange telphers are both also known as *runways.* All types under the above headings serve, so to speak, for interdepartmental vehicular goods traffic. While ordinary vehicular traffic runs on a pair of rails on the ground, the receptacles or skips of monorails and telphers are suspended from one overhead rail. Overhead traffic has the advantage over that on ground rails in that the track does not encumber the ground, which is a matter of importance, particularly in congested aisles and passages on the factory floor. The overhead rail from which the receptacles are suspended occupies space which is of lesser value. Conditions obtain in many cases which make it absolutely imperative to convey on a path well above ground. Overhead monorail tracks are unobstructed and therefore offer less resistance to the movement of the receptacles, which, having generally only two wheels, run more easily than those on ground rails, which have four, because the friction is less. Monorail receptacles when electrically driven can be at any height above ground, or if pushed by a man walking on the ground they may be just high enough for him to reach them. A single to-and-fro track may be employed when only one unit of the telpher machine, as the rolling stock is called, can be used; but a double or endless track, *i.e.*, joined together at the two terminals, which passes all the points to be served, is the ideal solution, because it provides for one-way traffic and a number of units can travel in unbroken succession. This is of particular importance in the case of overhead traffic, where individual loads are handled rather than a train of several, as is the case with ordinary ground traffic. The track can be so arranged as to lead in and out of shops, also round buildings, at relatively sharp angles and even slight inclines, and may also be provided with branch lines. It may be supported from the ceiling or some other part of the building or, if in the open, from steel or wooden structures. In small installations the track may be a light rail of selected section or it may consist merely of a flat iron bar. The receptacles are suspended from a two-wheeled trolley or runner on the rail. When switches are employed great care must be taken to leave no open track ends, since they might be the cause of serious accidents. A variety of such switches are now on the market.



BY COURTESY OF THE VEREIN DEUTSCHER INGENIEURE

FIG. 1.—MONORAIL AS USED IN A FOUNDRY

The First Telpher.—*The telpher* was invented in 1882 by Professor Fleeming Jenkin, and the name given by him, derives from two Greek words, *tele,* far; and *pherein,* to carry. In working out his invention Professor Jenkin collaborated with Professors Ayrton and Parry. The first installation was erected at Glynde, in Sussex, on Lord Hampden's estate, and was for handling clay from a brick-field. It was a perfect success. The cost of transport was a little under 4d. per ton-mile. The track in this first example, unlike that of the modern telpher, consisted of two steel cables and not a rigid rail. The material was transported by an electrically operated tractor having ten carriers, five of which were pushed and the other five pulled. A modern telpher

is a self-contained, electrically operated unit and consists essentially of a suitable bogie or trolley, running on an overhead rail, from which is supported one receptacle to carry the load. The bogie is fitted with, and propelled by, an electric motor, which collects its current by a small trolley pole from a single, double or triple live rail supported on the track structure. The telpher may be what is known as a "man-telpher" (though frequently driven by a woman), *i.e.* accompanied by an attendant who, from the cab, starts, stops, receives or dumps the load and returns for a further one, or it may be controlled automatically, so that it travels when released at the loading platform to a predetermined, though variable destination, where it dumps its load automatically and returns again to the starting point. Man-telphers are generally fitted with one or two electric winches for picking up loads from ground level at any part of the line and laying them down at any other. Monorail telphers are suitable for heavy loads of, for instance, from 1 ton up to 5 tons net; and the speeds of travel may be anything from 50oft. up to 1,000ft. per minute, according to the nature and length of the run. The lifting speeds range from 60ft. per minute with heavy loads, to 200ft. per minute with light loads and long lifts. For loads up to a maximum of 1 ton the bottom-flange telpher is more suitable. Speeds of travel are slower than those mentioned above. Both types are equally applicable in their particular fields. Theoretically, there is no limit to the conveying distance of a telpher, but for economic reasons the allied "ropeway" (*q.v.*) is generally preferred where distances of a quarter of a mile and over have to be traversed. Monorail telphers are frequent in gas and electricity undertakings.

Automatic Telphers.—Automatic telphers are often provided with a perfect automatic block system, so that each passing telpher establishes its own connections and no second machine can enter the line within a predetermined distance from the one in front, while if that one stops all succeeding machines will keep the same distance apart. These automatic devices are, as yet, very little used in Great Britain; they are, on the other hand, employed frequently on the Continent.

See Herbert Blyth, *Modern Telpherage and Ropeways* (1926).

(G. F. Z.)

MONOTHELITES, in Church history, the name given to those who, in the 7th century, while otherwise orthodox, maintained that Christ had only one will. Their theory was an attempt to effect some kind of solution of the vital unity of Christ's person on the basis of the now firmly-established doctrine of the two natures. The controversy had its origin in the efforts of the emperor Heraclius to win back for the church and the empire the excommunicated and persecuted Monophysites or Eutychians of Egypt and Syria. In Egypt especially the monophysite movement had assumed a nationalistic, patriotic character. It was in Armenia, while on his expedition against Persia, in 622 that, in an interview with Paul, the head of the Severian Monophysites (*q.v.*) there, Heraclius first broached the doctrine that the divine and human natures in Christ, while quite distinct in his one person, had but one activity and operation. Sergius, patriarch of Constantinople, was a strong upholder of the doctrine of one divine-human energy (*μία θεανδρική ἐνέργεια*), and was the emperor's adviser on the whole question. The emperor's action led to such intense and widely-spread controversy that his successor Constans II. issued an edict forbidding all discussion of the questions of the duality or singleness of either the energy or the will of Christ. The scheme of doctrine of the first four general councils, with all its vagueness as to these points, was to be maintained; so far as controversy had gone, the disputants on either side were to be held free from censure; but to resume it would involve penal consequences. This decree secured silence, notwithstanding the protest of the Western Church at the Lateran Council of 649; but with the accession of Constantine Pogonatus in 668 the controversy once more revived, and the new emperor resolved to summon a general council. It met at Constantinople in 680, having been preceded in 679 by a brilliant synod under Pope Agatho at Rome, where it had been agreed to depart in nothing from the decrees of the Lateran synod. The will, Agatho said, is a property of the nature, so that as there are two natures there are two wills; but the human will determines itself ever conformably to the divine and almighty will.

MONOTREMATA, the lowest existing order of mammals, including the duck-billed platypus of Australia and the echidnas or spiny anteaters of Australia and New Guinea. Unlike all other existing mammals, these animals lay eggs; their right and left oviducts remain separate, not uniting to form a median uterus, and the ducts, leading respectively from the ovaries or testes, from the bladder and from the digestive tract, all open into a single cloaca or common outlet (whence the name Monotremata).

The platypus (*q.v.*) is adapted for semi-aquatic life, having an otter-like form, with webbed feet; it is covered with smooth sleek fur and has a long beaver-like tail. It eats small crustaceans, worms and insect larvae, obtaining them by nuzzling in the mud with its duck-like bill. It has true molar teeth when young, but later these are replaced by horny plates.

The echidna (*q.v.*) lives in dry country, is covered with quills and coarse hair and has a short tail and a long pointed toothless bill with an extensile tongue for feeding upon ants. It is more compactly built than the platypus and has immense strength for digging. The New Guinea echidna (*Zaglossus*) is larger, and has a very long bill and short spines almost covered by long under-fur.

In 1792 the "spiny anteater" of New South Wales, Australia, was described and figured by Shaw, as *Myrmecophaga aculeata,* the impression of the author being that it was related to the South American anteater. In 1799 Shaw published the first description and figures of the duckbill, naming it the *"Platypus anatinus,"* and noting the beaver-like tail and body, the serrated duck-like bill, the small eyes, the ear-holes behind the eyes, the webbed and clawed feet and other details. He came to the conclusion that it must be a resident in watery situations; that it has the habits of digging or burrowing in the banks of rivers, or underground; and that its food consists of aquatic plants and animals.

In 1800 Blumenbach received a stuffed specimen collected by Sir Joseph Banks, which he described under the name *"Ornithorhynchus paradoxus,"* referring it to the Edentata (*q.v.*). The generic name *Platypus* of Shaw had already been invented by another author for a genus of beetles, so that the correct scientific name of the typical species is *Ornithorhynchus anatinus;* but the name platypus is now the common one for the animal.

In 1802 Home published a description of the anatomy of two spirit specimens of the platypus, in which he noted that "the structure of the female organs is unlike anything hitherto met with in quadrupeds. . . ." He was led to examine the corresponding parts in birds and reptiles and found most resemblance to the organs of ovo-viviparous lizards. Later in the same year Home examined the anatomy of the spiny anteater. He at once recognized its affinity to the platypus and included it in the same genus as *"Ornithorhynchus hystrix."* Home also concluded that *Ornithorhynchus* represented a new tribe of quadrupeds, "so that it may be considered as an intermediate link between the classes Mammalia, Aves and Amphibia. . . . Between it and the bird, no link of importance seems to be wanting." Thus arose the misleading and still widely prevalent notion that the platypus is a link between mammals and birds, whereas its true position is more that of a link between mammals and reptiles.

In 1803 Etienne Geoffroy, the colleague of Cuvier, established a new order, Monotremata, characterized by: "Digits clawed, no true teeth; a common cloaca opening to the exterior by a single orifice." In 1809 Lamarck added a class, Prototheria, for the platypus and echidna, deciding that they were not mammals, for they had no mammary glands and were probably oviparous; they were not birds, for their lungs differed, and they had no wings; and they were not reptiles, for they possessed a four-chambered heart. Then followed a long argument whether the monotremes were to be classed as mammals. Finally in 1834 De Blainville arranged the mammals under three subclasses: (1) Ornithodelphia (bird-like uteri): including the monotremes; (2) Didelphia

(double uteri): including the marsupials; (3) Monodelphia (single uteri): including the placental mammals. In 1884 Caldwell obtained evidence enabling him to cable to the British Association meeting at Montreal, "Monotremes oviparous, ovum meroblastic." In 1891 Richard Semon secured monotreme material in Queensland, including new-laid eggs and a series of embryos of the echidna. He deduced that the egg of echidna, unlike the eggs of reptiles or birds, grows within its shell by receiving nutriment through the shell from the uterine tissues of the mother. During the past 20 years H. Burrell, working under Professor Launcelot Harrison, has given accurate descriptions of the underground tunnels dug by the platypus, and of the carefully constructed nests of leaves and grass in which their eggs are laid.

According to J. T. Wilson and J. P. Hill, the ovum of the platypus at the time of fertilization is about three millimeters in diameter; after fertilization it becomes surrounded by an exceedingly thin layer of albumen, and outside this by a thin transparent horny shell. It grows to a length of 16–18mms. before oviposition. The eggs, which resemble those of certain lizards, are usually laid in pairs which stick together. Burrell infers that when the eggs are laid the animal is sitting curled-up and receives them in its forepaws, by which they are placed between the curled-in tail and the abdomen, where they are brooded. For some time after the young are hatched no milk is secreted; the young when born have a very short bill with "lips." There are no teats but the young lick and suck the milk from the surface of the mammary field. In the platypus there is no pouch but in the echidna a "brood pouch" is developed.

While the platypus and the echidna differ widely in habits, external appearance and in skeletal and anatomical characters connected with the difference in "habitus," they have many important features in common. For instance, both possess a peculiar poison-secreting apparatus, in some ways analagous with those of poisonous snakes. The fang, represented by a large horny spur attached to each ankle of the male, is better developed in the platypus than in the echidna. The sharp tip of the spur is perforated by a canal leading to a duct running up the leg to a large gland beneath the skin on the upper surface of the femur. The albuminous secretion is poisonous but not fatal to other mammals. The spurs are used in fighting between the males during the breeding season and also serve for clasping the females.

The existing monotremes are definitely excluded from ancestry to the marsupials or placental mammals by the possession of such curious specializations as the poison gland and tarsal spur. In the other direction there is no known group of extinct Mesozoic mammals from which we may confidently derive the monotremes. Notwithstanding the widespread impression that the monotremes have been derived from the extinct Multituberculata, recently discovered palaeontological evidence weighs heavily against this view. The anatomy of the monotremes reveals many important features of the brain and skeleton in common with the marsupials, to which group indeed they appear to be more nearly related than to the placental mammals.

(W. K. G.)

MONOTRIGLYPH, in architecture, a term describing the most common intercolumniation (*q.v.*) of the Greek Doric order, in which one triglyph separates the triglyphs over the centres of adjacent columns.

MONOTYPES. A monotype is a unique print, taken either by passing the metal plate on which the picture has been done through a printing press, like an etching or engraving, or by hand-rubbing, like a woodcut, which is less effective, or, perhaps better still, by rubbing with an ivory or bone paper-knife. By the last process the paper can be lifted now and again, so that the progress of the print may be watched, and more or less pressure exerted where it is necessary to emphasize the gradations of dark or light, for the print is really an emotional effect, and it must not be forgotten that the plate has not been engraved at all. The subject has been either painted direct in oils or thick inks at a single sitting, or the plate has been thinly covered with ink or dark paint, not too oily, then the subject has been gradually evolved by the manipulation of the lights with the finger, a rag, or a brush, to suggest form by a full range of tone, as the lights are scraped away in mezzotint. A monotype resembles a mezzotint in effect, with its rich velvety blacks, and subtle half-tones, but to ensure a successful print, it must be taken while the paint is wet. Since only one print can be obtained, the method seems scarcely worth while, except for the fun of the thing. In recent years, many artists have amused themselves with it. Indeed, Sir Hubert Herkomer was an enthusiast, and with his natural zest for experiment he dusted the plate with powder, to suggest the effect of a grain; then he made a mould or electrotype, so that impressions could be taken, but it then, of course, ceased to be a monotype. (*See* also PRINTING.) (M. C. S.)

MONREALE (*monte-reale*, from a palace built by Roger I.), a town, Sicily, province of Palermo, 5m. inland from the city, on the slope of Monte Caputo, overlooking the valley *"La Conca d'oro"* (the Golden Shell), famed for its orange, olive and almond trees. Pop. (1921), 22,511 (town); 23,966 (commune).

A large Benedictine monastery, the church of which was the seat of the metropolitan archbishop of Sicily, was the greatest of all monuments of the Normans in northern Sicily. Begun in 1174 by William II., in 1182 the church was dedicated to the Assumption of the Virgin Mary and made a metropolitan cathedral. The archiepiscopal palace and monastic buildings on the south were surrounded by a massive precinct wall, crowned at intervals by twelve towers. Little now remains except ruins of some of the towers, a great part of the monks' dormitory and frater, and the splendid cloister, completed about 1200.

The plan of the church is Lombardo-Norman. The basilican nave is wide, with narrow aisles. Monolithic columns of grey oriental granite (except one of cipollino), with Corinthian capitals, support eight pointed arches on each side much stilted. There is a high clerestory with wide two-light windows, with simple tracery like those in the nave-aisles and throughout the church. The other half, both wider and higher than the nave, is divided into a central space with two aisles, each of the divisions ending at the east with an apse. The roofs throughout are of open rich coloured woodwork very low in pitch. At the west end of the nave are two projecting towers, with a narthex-entrance between them. A large open atrium, which once existed at the west, has been replaced by a Renaissance portico. The exterior of the aisle walls and three eastern apses is decorated with intersecting pointed arches and other ornaments inlaid in marble. The outsides of the principal doorways and their pointed arches are magnificently carved and inlaid.

The enormous extent (70,400 sq.ft.) and glittering splendour of the glass mosaics covering the interior are remarkable. With the exception of a high dado made of marble slabs with bands of mosaic between them, the whole interior surface of the walls is covered with minute mosaic-pictures in brilliant colours on a gold ground. The mosaic pictures are arranged in tiers, divided by horizontal and vertical bands (in parts of the choir as many as five tiers).

In the central apse at Monreale, behind the high altar, is a fine marble throne for the archbishop. On the north side, in front of the high altar, is a throne for the king. The tomb of William I., the founder's father, and the founder William II.'s tomb, erected in 1575, were both shattered by fire in 1811. On the north of the choir are the tombs of Margaret, wife of William I., and her two sons Roger and Henry, together with an urn containing the viscera of St. Louis of France. The pavement of the triple choir is a very magnificent specimen of marble and porphyry mosaic in *opus alexandrinum.*

Two bronze doors, north and west of the church, are divided into square panels with subjects and single figures, chiefly from Bible history, cast in relief. That on the north is by Barisanus of Trani. The cathedrals at Trani and Ravello also have bronze doors by him. The western door at Monreale, inferior to the northern one both in richness of design and in workmanship, is

by Bonannus of Pisa, for the cathedral of which he cast the bronze door on the south. The one at Monreale is inscribed A.D. MCLXXXVII IND. III. BONANNUS CIVIS PISANVS ME FECIT. The monastic library contains some valuable mss., especially a number of bilinguals in Greek and Arabic, the earliest dated 1144.

See D. B. Gravina, *Il Duomo di Monreale* (Palermo, 1859–65). (J. H. Mi.; T. A.)

MONRO, SIR CHARLES CARMICHAEL, 1st. Bart. cr. 1921 (1860–1929), British soldier, was born on June 15, 1860, and joined the army in 1879. In 1897–98 he saw service at Malakand, in the Mohmand country, in Bajour and in Tirah and he was on the staff in South Africa (1899–1902). He was afterwards commandant of the school of musketry at Hythe, Kent. Having commanded the 2nd Division in the first fighting in 1914, Monro was, at the end of 1914, placed in command of the I. Army Corps, and on a III. Army being organized in July 1915, he was given charge of this. He was chosen in October to take over the command of the Mediterranean Expeditionary Force and to decide whether the campaign in the Gallipoli Peninsula was to be continued. Monro acted with rare decision. Although the Government was disposed to cling to the peninsula, he insisted upon its abandonment, and he was, after some delay, allowed to have his way, with the result that the forces were withdrawn from a most dangerous position without appreciable loss. He returned to the Western Front, but in Oct. 1916 he became commander-in-chief in India. From 1923 to 1928 he was governor and commander-in-chief of Gibraltar. He died in London, on Dec. 7, 1929.

MONRO, DAVID BINNING (1836–1905), English Homeric scholar, was born in Edinburgh on Nov. 16, 1836. He was educated at Glasgow university, and Brasenose and Balliol colleges, Oxford, and was provost of Oriel till his death at Heiden, Switzerland, on Aug. 22, 1905. After producing his *Grammar of the Homeric Dialect* (2nd ed. 1891) he edited the last 12 books of the *Odyssey,* and published a critical text of the poems and fragments (*Homeri opera et reliquiae,* 1896); *Homeri opera* (1902, in the Oxford texts); and an edition of the *Iliad* with notes for schools. He wrote the article on Homer for the 9th edition of the *Encyclopædia Britannica;* also *Modes of Ancient Greek Music* (1894) (see *Classical Review,* Dec. 1894 and Feb. 1895).

See *Memoir* by J. Cook Wilson (1907).

MONROE, JAMES (1758–1831), fifth president of the United States, was born on Monroe's creek, in Westmoreland county, Virginia, on April 28, 1758. His father, Spence Monroe, was of Scottish, and his mother, Elizabeth Jones, of Welsh descent. At the age of 16 he entered the College of William and Mary, Williamsburg, Va., but in 1776 he left college to take part in the Revolutionary War. He enlisted in the Third Virginia regiment, in which he became a lieutenant, and subsequently took part in the battles of Harlem Heights, White Plains, Trenton (where he was wounded), Brandywine, Germantown and Monmouth. In 1780 he began the study of law under Thomas Jefferson, then governor of Virginia, and between the two there developed an intimacy and a sympathy that had a powerful influence upon Monroe's later career.

In 1782 he was elected to the Virginia house of delegates, and though only 24 years of age he was chosen a member of the governor's council. He served in the Congress of the Confederation from 1783 to 1786 and was there conspicuous for his vigorous insistence upon the right of the United States to the navigation of the Mississippi river, and for his attempt, in 1785, to secure for the weak Congress the power to regulate commerce, in order to remove one of the great defects in the existing central government. On retiring from Congress he began the practice of law at Fredericksburg, Va., was chosen a member of the Virginia house of delegates in 1787, and in 1788 was a member of the State convention which ratified for Virginia the Federal constitution. In 1790 he was elected to the United States senate and although in this body he vigorously opposed Washington's administration, Washington in 1794 nominated him as minister to France. It was the hope of the administration that Monroe's well-known French sympathies would secure for him a favourable reception, and that his appointment would also conciliate the friends of France in the United States. His warm reception in France and his enthusiastic Republicanism, however, displeased the Federalists at home; he did nothing, moreover, to reconcile the French people to the Jay treaty (*q.v.*), which they regarded as a violation of the French treaty of alliance of 1778 and as a possible *casus belli.* The administration therefore decided that he was unable to represent his government properly and late in 1796 recalled him.

Monroe returned to America in the spring of 1797, and in the following December published a defence of his course in a pamphlet of 500 pages entitled *A View of the Conduct of the Executive in the Foreign Affairs of the United States.* Washington seems never to have forgiven Monroe for this, though Monroe's opinion of Washington and Jay underwent a change in his later years. In 1799 Monroe was chosen governor of Virginia and was twice re-elected, serving until 1802. At this time there was much uneasiness in the United States as a result of Spain's restoration of Louisiana to France by the secret treaty of San Ildefonso, in Oct. 1800; and the subsequent withdrawal of the "right of deposit" at New Orleans by the Spanish intendant greatly increased this feeling and led to much talk of war. Resolved upon peaceful measures, President Jefferson in Jan. 1803, appointed Monroe envoy extraordinary and minister plenipotentiary to France to aid Robert R. Livingston, the resident minister, in obtaining by purchase the territory at the mouth of the Mississippi, including the island of New Orleans, and at the same time authorized him to co-operate with Charles Pinckney, the minister at Madrid, in securing from Spain the cession of East and West Florida. On April 18, Monroe was further commissioned as the regular minister to Great Britain. He joined Livingston in Paris on April 12, after the negotiations were well under way; and the two ministers, on finding Napoleon willing to dispose of the entire province of Louisiana, decided to exceed their instructions and effect its purchase. Accordingly, on April 30, they signed a treaty and two conventions, whereby France sold Louisiana to the United States (*see* Louisiana Purchase). In July 1803 Monroe left Paris and entered upon his duties in London; and in the autumn of 1804 he proceeded to Madrid to assist Pinckney in his efforts to secure the definition of the Louisiana boundaries and the acquisition of the Floridas. After negotiating until May 1805, without success, Monroe returned to London and resumed his negotiations concerning the impressment of American seamen and the seizure of American vessels. As the British ministry was reluctant to discuss these vexed questions, little progress was made, and in May 1806 Jefferson ordered William Pinkney of Maryland to assist Monroe. The British government appointed Lords Auckland and Holland as negotiators, and the result of the deliberations was the treaty of Dec. 31, 1806, which contained no provision against impressments and provided no indemnity for the seizure of goods and vessels. In passing over these matters Monroe and Pinkney had disregarded their instructions, and Jefferson was so displeased with the treaty that he returned it to England for revision. Just as the negotiations were reopened, however, the questions were further complicated and their settlement delayed by the attack of the British ship "Leopard" upon the American frigate "Chesapeake." Monroe returned to the United States in Dec. 1807, and was elected to the Virginia house of delegates in the spring of 1810. In the following winter he was again chosen governor, serving from Jan. to Nov. 1811, and resigning to become secretary of state under Madison, a position which he held until March 3, 1817. The direction of foreign affairs in the troubled period immediately preceding and during the second war with Great Britain thus devolved upon him. On Sept. 27, 1814, after the capture of Washington by the British, he was appointed secretary of war, and discharged the duties of this office, in addition to those of the state department, until March 1815.

In 1816 Monroe was chosen president of the United States; he received 183 electoral votes, and Rufus King, his Federalist opponent, 34. In 1820 he was re-elected, receiving all the electoral votes but one, which William Plumer (1759–1850) of New Hampshire cast for John Quincy Adams, in order, it is said, that no one might share with Washington the honour of a unanimous election. The chief events of his administration, which has been

called the "era of good feeling," were the Seminole War (1817–18); the acquisition of the Floridas from Spain (1819–21); the "Missouri Compromise" (1820), by which the first conflict over slavery under the constitution was peacefully adjusted; the veto of the Cumberland Road bill (1822) on constitutional grounds; and—most intimately connected with Monroe's name—the enunciation in the presidential message of Dec. 2, 1823, of what has since been known as the Monroe Doctrine (*q.v.*), which has profoundly influenced the foreign policy of the United States.

On the expiration of his second term Monroe retired to his home at Oak Hill, Loudoun county, Virginia. In 1826 he became a regent of the University of Virginia, and in 1829 was a member of the convention called to amend the state constitution. Having neglected his private affairs and incurred large expenditures during his missions to Europe, he experienced considerable pecuniary embarrassment in his later years, and was compelled to ask Congress to reimburse him for his expenses in the public service. Congress finally (in 1826) authorized the payment of $30,000 to him, and after his death appropriated a small amount for the purchase of his papers from his heirs. He died in New York city on July 4, 1831, while visiting his daughter. In 1858, the centennial year of his birth, his remains were reinterred with impressive ceremonies at Richmond, Virginia. Jefferson, Madison, John Quincy Adams, Calhoun and Benton all speak loudly in Monroe's praise; but he suffers by comparison with the greater statesmen of his time. Possessing none of their brilliance, he had, nevertheless, to use the words of John Quincy Adams, "a mind . . . sound in its ultimate judgments, and firm in its final conclusions." Schouler points out that like Washington and Lincoln he was "conspicuous . . . for patient considerateness to all sides." Monroe was about 6ft. tall, but, being stoop-shouldered and rather ungainly, seemed less; his eyes, a greyish blue, were deep-set and kindly; his face was delicate, naturally refined, and prematurely lined. The best-known portrait, that by Vanderlyn, is in the New York City Hall. Monroe was married in 1786 to Elizabeth Kortwright (1768–1830) of New York, and at his death was survived by two daughters.

Irelan, *History of the Life, Administration and Times of James Monroe,* being vol. v. of his *Republic* (Chicago, 1887); John Quincy Adams, *The Lives of James Madison and James Monroe* (Buffalo, 1850); B. W. Bond, jun., *Monroe's Mission to France, 1794–1796* (Baltimore, 1907); Henry Adams, *History of the United States* (1889–91), containing a full but unsympathetic account of Monroe's career as a diplomatist; and James Schouler, *History of the United States,* vols. ii. and iii. (1894), which estimates his public services highly. For more recent estimates see George Morgan, *The Life of James Monroe* (Boston, 1921); and William A. McCorkle, *The Personal Genesis of the Monroe Doctrine* (1923); and "Text from Messages Enunciating Famous Monroe Doctrine and Roosevelt Corollary," *Cong. Digest,* vol. vi., p. 114–115 (1927).

MONROE, a city of northern Louisiana, U.S.A., the capital of Ouachita parish; on the east bank of the Ouachita river, 96 m. east of Shreveport. It is on Federal highways 80 and 165; has a municipal airport of 140 ac.; and is served by the Arkansas and Louisiana Midland, the Illinois Central and the Missouri Pacific railways, and river barges and steamers. Pop. (1920) 12,675 (44% negroes); and was 26,028 Federal census 1930. West Monroe, on the opposite bank of the river, had a population given as 6,566 in 1930. Monroe is the centre of the largest known gas field in the world, covering 400 sq.m., with an available reserve estimated in 1927 at 2,200,000 million cu.ft. Its trade territory extends over nine parishes. The manufactures in and near the city include pulp and paper, carbon black, printer's ink, lumber and lumber products, brick, candy, brooms and mattresses. The annual payroll is about $8,000,000 and in 1927, bank clearings were $116,068,250. A Spanish settlement (called Ouachita Post, and later Fort Miró) was established here in 1785. It was renamed, after President Monroe, in 1819; incorporated as a town in 1820, and chartered as a city in 1871. In 1902 a commission form of government was adopted.

MONROE, a city of south-eastern Michigan, U.S.A., 35 m. S.W. of Detroit, on Lake Erie, at the mouth of the Raisin river; the county seat of Monroe county. It is on Federal highways 24 and 25, and is served by the Detroit and Toledo Shore Line, the Michigan Central, the New York Central, the Pennsylvania, the Pere Marquette and electric railways. The population was 11,573 in 1920 (90% native white) and was 18,110 in 1930 by the Federal census. It is the seat of St. Mary's college for girls (Roman Catholic; 1910); has extensive nurseries; and is an important manufacturing centre, with an output in 1925 valued at $21,598,284. Fibre and straw-paper board, paper, tile, sash and blinds, furniture, flour, stokers, gasolene engines and furnaces are among the leading products. Monroe was settled by French Canadians in 1783, and was known as Frenchtown. In Jan., 1813, the inhabitants prayed the Americans for protection against the British and their Indian allies, and on Jan. 18 a detachment sent from the army of Gen. James Winchester drove out a small force of British. The general arrived three days later, with more men, but at dawn on Jan. 22 he was surprised by Col. Henry A. Proctor and forced to surrender. In 1815 the town was renamed in honour of James Monroe, then Secretary of State. It was made the county seat in 1817, incorporated as a village in 1827, and chartered as a city in 1837.

MONROE, a city of North Carolina, U.S.A., the county seat of Union county; on Federal highway 74 and the Seaboard Air Line railway, 22 m. S.E. of Charlotte. The population was 4,084 in 1920 (26% negroes) and 6,100 in 1930.

MONROE, a city near the southern boundary of Wisconsin, U.S.A., served by the Chicago, Milwaukee, St. Paul and Pacific and the Illinois Central railways; the county seat of Green county. Pop. (1930) 5,015. It is the centre of a blue-grass region which produces a large part of the "Swiss" and other foreign-type cheeses made in the United States. The output of the county in 1927 was 15,912,320 pounds. The industry was established by a Swiss colony of 155 persons who in 1845 settled in the hills about 15 m. N. of Monroe (because it was more like Switzerland than any other place they had seen in America) and founded the village of New Glarus. After 20 years of great poverty, making a bare living by raising wheat (which exhausted the soil) they seeded the fields with clover and grass, and developed commercially the cheese-making which had been carried on for domestic consumption. Gradually it spread over the county, transforming it into a vast dairy farm, covered with great herds of Holstein and brown Swiss cattle, mammoth barns and tall silos. Monroe was founded in 1832 and incorporated in 1859.

MONROE DOCTRINE, THE, was the fruition of early American policy. There had long been a deep-seated conviction on the part of the people of the United States that the opportunities of a hard-won freedom would be threatened by the ambitions of European powers and that the aims of the new nation could be achieved only by keeping clear of the toils of European politics and strife. It was this conviction of the necessity of maintaining an independent position which led to the declaration of neutrality in 1793, despite the Treaty of Alliance with France which had sprung from the exigencies of the Revolutionary struggle. The words of Washington's Farewell Address were more than a solemn admonition; they stated cherished principles. "The great rule of conduct for us," he said, "in regard to foreign nations, is, in extending our commercial relations, to have with them as little *political* connection as possible. . . . Europe has a set of primary interests which to us have none, or a very remote relation. Hence she must be engaged in frequent controversies, the causes of which are essentially foreign to our concerns. Hence therefore it must be unwise in us to implicate ourselves, by artificial ties in the ordinary vicissitudes of her politics, or the ordinary combinations and collisions of her friendships, or enmities." The people of the United States had watched with deep sympathy the long struggle of their southern neighbours for independence. While Spain maintained a doubtful contest, it was regarded as a civil war, but when that contest became so desperate that Spanish viceroys, governors, and captains-general concluded treaties with the insurgents virtually acknowledging their independence, the United States unreservedly recognized the facts. The republic of Colombia was recognized in 1822, the Government of Buenos Aires

and the States of Mexico and Chile early in 1823. The United States was the first to recognize the independent empire of Brazil in May, 1824, not hesitating because of the political form of the Government, and this was followed by the recognition of the Federation of Central American States in August of the same year. Meanwhile, the Holy Alliance formed by the sovereigns of Austria, Russia and Prussia had sought to enforce the divine right of kings against the progress of liberal principles. Joined by France, they undertook "to put an end to the system of representative government" and after France had proceeded accordingly to restore the rule of Ferdinand VII. in Spain, it was proposed to direct their efforts to the overthrowing of the new Governments erected out of the old colonies of Spain in the western hemisphere.

MONROE'S MESSAGE

This was the situation when, in Aug. 1823, George Canning, British foreign secretary, wrote to Richard Rush, American minister in London, suggesting a joint declaration in substance that the recovery of the colonies by Spain was hopeless; that neither Great Britain nor the United States was aiming at the possession of any portion of these colonies; and that they could not see with indifference any portion of them transferred to any other power. Great Britain, however, had not at that time recognized the new States in Spanish America. President Monroe sought the advice of Jefferson and Madison. Jefferson regarded the question as "the most momentous" which had arisen since that of Independence. "Our first and fundamental maxim," said he, "should be, never to entangle ourselves in the broils of Europe. Our second, never to suffer Europe to intermeddle with cis-Atlantic affairs." Jefferson favoured the acceptance of the British suggestion in some form and Madison took the same view. John Quincy Adams, Secretary of State, opposed a joint declaration. He wished to take the ground "of earnest remonstrance against the interference of the European powers by force with South America, but to disclaim all interference on our part with Europe; to make an American cause and adhere inflexibly to that." Upon the advice of Adams, and after mature deliberation by the president and his cabinet, it was decided to make a separate declaration on the sole responsibility of the United States, and this declaration was formulated in the president's message of Dec. 2, 1823.

Original Statement of the Doctrine.—The doctrine is set forth in two paragraphs of this message. The first of these had a genesis distinct from the situation of the former colonies of Spain. It grew out of the question of Russian claims on the north-west coast of North America. The Russian emperor had issued a ukase in 1821 prohibiting citizens of other nations from navigating and fishing within 100 Italian miles of the north-west coast of North America from Bering straits to the 51st parallel of north latitude. Protests had followed. In July, 1823, Secretary Adams informed the Russian minister that the United States "should contest the right of Russia to any territorial establishment on this continent, and that we should assume distinctly the principle that the American continents are no longer subjects for any new European colonial establishments." It was in connection with this situation that President Monroe, after adverting to the proposal of arranging the respective rights and interests on the north-west coast by amicable negotiations, declared in his message:

"In the discussions to which this interest has given rise, and in the arrangements by which they may terminate, the occasion has been judged proper for asserting as a principle in which the rights and interests of the United States are involved, that the American continents, by the free and independent condition which they have assumed and maintained, are henceforth not to be considered as subjects for future colonization by any European powers."

The other paragraph of President Monroe's message bore upon the situation of the nations to the south of the United States, as follows:

"In the wars of the European powers in matters relating to themselves we have never taken any part, nor does it comport with our policy so to do. It is only when our rights are invaded or seriously menaced that we resent injuries or make preparation for our defence. With the movements in this hemisphere we are, of necessity, more immediately connected, and by causes which must be obvious to all enlightened and impartial observers. The political system of the allied powers is essentially different in this respect from that of America. . . . We owe it, therefore, to candour, and to the amicable relations existing between the United States and those powers, to declare that we should consider any attempt on their part to extend their system to any portion of this hemisphere as dangerous to our peace and safety. With the existing colonies or dependencies of any European power we have not interfered and shall not interfere. But with the governments who have declared their independence and maintained it, and whose independence we have, on great consideration and on just principles, acknowledged, we could not view any interposition for the purpose of oppressing them, or controlling in any other manner their destiny, by any European power, in any other light than as the manifestation of an unfriendly disposition toward the United States. . . . It is impossible that the allied powers should extend their political system to any portion of either continent without endangering our peace and happiness; nor can any one believe that our southern brethren, if left to themselves, would adopt it of their own accord. It is equally impossible, therefore, that we should behold such interposition, in any form, with indifference."

The message, so far as it related to the revolted Spanish colonies, had widespread approval in England. Three years later, Canning made his famous boast that he had "called the New World into existence to redress the balance of the Old." There was, indeed, general agreement between the sentiments of the Governments of Great Britain and the United States as to the Spanish colonies, but this was qualified, as Canning himself had pointed out, by the important difference that the United States had acknowledged the independence of the new Governments and the British Government had not. With the portion of President Monroe's message relating to future colonization, which lay outside the purview of Canning's suggestion, Canning was not in sympathy. This proposal was as new to the British Government as it was to France. The basis of the objection on the part of the United States to future colonization by European powers was found in the fact, as John Quincy Adams said later, when president, that "With the exception of the existing European colonies, which it was in no wise intended to disturb, the two continents consisted of several sovereign and independent nations, whose territories covered their whole surface. By this, their independent condition, the United States enjoyed the right of commercial intercourse with every part of their possessions. To attempt the establishment of a colony in those possessions, would be to usurp to the exclusion of others a commercial intercourse which was the common possession of all." Manifestly, it was not intended to assert that there were no unoccupied lands, for there were vast regions of territory not actually settled by the subjects of civilized powers, but the declaration proceeded in the view "that the several American territorial sovereigns enjoyed by virtue of constructive occupation, exclusive rights of ownership and sovereignty which should be respected."

Later Extension or Modification.—Not only did the statesmen of the United States fear the extension of European colonization, but they viewed with deep concern the possibility of the transfer of American territory from one European power to another, or the transfer of such territory from an American to a non-American power. In 1811, the Congress of the United States passed a resolution as to East Florida, stating that "considering the influence which the destiny of the territory adjoining the southern border of the United States may have upon their security, tranquillity, and commerce," the United States could not, "without serious inquietude, see any part of the said territory pass into the hands of any foreign power." The declarations in the messages of President Polk in 1845 and 1848 were so closely associated with the doctrine announced by Monroe that they may be deemed to fall within the same governing principle. With reference to the case of Yucatan, when the authorities of the country offered to transfer the dominion and sovereignty to the United States and at the same time made a similar offer to Great Britain and Spain, President Polk said: "Whilst it is not my purpose to recommend the adoption of any measure, with a view to the acquisition of the 'dominion and sovereignty' over Yucatan, yet, according to our established policy, we could not consent to a transfer of this 'dominion and sovereignty' to either Spain, Great Britain, or any other European power." President Polk's reference to the transfer of dominion and sovereignty evidently meant

opposition to the acquisition of territorial control by any means and this position has frequently been reiterated by the Government of the United States. In 1912, the Senate of the United States adopted a resolution, apparently having immediate reference to Magdalena bay, "that when any harbor or other place in the American continents is so situated that the occupation thereof for naval or military purposes might threaten the communications or the safety of the United States, the Government of the United States could not see without grave concern the possession of such harbour or other place by any corporation or association which has such a relation to another Government, not American, as to give that Government practical power or control for naval or military purposes." It was explained in support of the resolution that it rested on the principle of self-defence and that it was "allied to the Monroe Doctrine, of course, but not necessarily dependent upon it or growing out of it."

Since the declaration of Monroe, the famous Doctrine has been modified in only two particulars. What was said with Europe exclusively in view, must be deemed applicable to all non-American powers; and the opposition to the extension of colonization was not dependent upon the particular method of securing territorial control, and, at least since Polk's time, may be deemed to embrace opposition to acquisition of additional territory through transfer of dominion or sovereignty. Neither of these modifications changes the doctrine in its essentials and it may thus be summarized as being opposed (1) to any non-American action encroaching upon the political independence of American States under any guise, and (2) to the acquisition in any manner of the control of additional territory in the western hemisphere by any non-American power.

The United States has been alert in opposition to what was believed to involve action of this character. Historic instances are those relating to the Mosquito coast in 1858–60, the French intervention in Mexico ending in 1867, the arbitral settlement of the controversy as to the boundary line between Venezuela and British Guiana in 1895–97, and the disposition of the claims of Germany, Great Britain and Italy against Venezuela in 1902–04.

Character and Purport of the Doctrine.—The Monroe Doctrine is not a legislative pronouncement; it has been approved by action of Congress, but it does not rest upon congressional sanction. It is not defined by treaty, and it does not draw its force from any international agreement. It had, however, the implied endorsement of the treaty making power of the United States in the reservations to the two Hague Conventions of 1899 and 1907, which provided: "Nothing contained in this convention shall be construed as to require the United States of America to depart from its traditional policy of not intruding upon, interfering with, or entangling itself in the political questions of policy or internal administration of any foreign State; nor shall anything contained in the said convention be construed to imply a relinquishment by the United States of America of its traditional attitude toward purely American questions." The doctrine is not like a constitutional provision deriving its authority from the fact that it is a part of the organic law transcending and limiting executive and legislative power. While it is not a part of international law, it rests, as Elihu Root has stated, "upon the right of self-protection and that right is recognized by international law." It was asserted at a time when the danger of foreign aggression was very real, when the new American States had not yet established a firm basis of independent national life and republican institutions were menaced by the threats of Old World powers. But despite changes in conditions it still remains, to be applied if necessary, as a principle of national security. Its significance lies in the fact that in its essentials as set forth by President Monroe and as forcibly asserted by responsible statesmen, it has been for 100 years, and continues to be, an integral part of national thought and purpose expressing a profound conviction which even the upheaval caused by the World War, and the participation of the United States in that struggle upon European soil, did not upset.

The doctrine, as has been stated authoritatively, does not imply, or countenance, a policy of aggression. It does not infringe upon the independence and sovereignty of other American States. It does not attempt to establish a protectorate over Latin American States. The declaration that encroachment by non-American powers upon the independence of American States will be regarded as dangerous to the safety of the United States gives no justification for such encroachment on its part. In stating with extreme vigour the position of President Cleveland's administration in the correspondence with Great Britain relating to the Venezuela boundary, Secretary Olney recognized the limitations of the doctrine and his other statements should be read in the light of their context. He said: "The precise scope and limitations of this rule cannot be too clearly apprehended. It does not establish any general protectorate by the United States over other American states. It does not relieve any American state from its obligations as fixed by international law nor prevent any European power directly interested from enforcing such obligations or from inflicting merited punishment for the breach of them. It does not contemplate any interference in the internal affairs of any American state or in the relations between it and other American states. It does not justify any attempt on our part to change the established form of government of any American state or to prevent the people of such state from altering that form according to their own will and pleasure. The rule in question has but a single purpose and object. It is that no European power or combination of European powers shall forcibly deprive an American state of the right and power of self-government and of shaping for itself its own political fortunes and destinies." President Roosevelt in his annual message of 1901 thus referred to the doctrine: "It is in no wise intended as hostile to any nation in the Old World. Still less is it intended to give cover to any aggression by one New World power at the expense of any other. It is simply a step, and a long step, toward assuring the universal peace of the world by securing the possibility of permanent peace on this hemisphere." And in his annual message of 1906, President Roosevelt said: "In many parts of South America there has been much misunderstanding of the attitude and purposes of the United States toward the other American republics. An idea had become prevalent that our assertion of the Monroe Doctrine implied or carried with it an assumption of superiority and of a right to exercise some kind of protectorate over the countries to whose territory that doctrine applies. Nothing could be farther from the truth."

As the policy embodied in the Monroe Doctrine was distinctively the policy of the United States, the Government of the United States has reserved to itself its definition and application. President Wilson observed: "The Monroe Doctrine was proclaimed by the United States on her own authority. It always has been maintained, and always will be maintained, upon her own responsibility." But it has frequently been stated that the United States would welcome the adoption by the other American republics of a similar policy. President Wilson sought to give the principles of the doctrine a world-wide application. In his address to the Senate on Jan. 22, 1917, he said: "I am proposing, as it were, that the nations should with one accord adopt the doctrine of President Monroe as the doctrine of the world; that no nation should seek to extend its polity over any other nation or people, but that every people should be left free to determine its own polity, its own way of development, unhindered, unthreatened, unafraid, the little along with the great and powerful." The Covenant of the League of Nations refers to the doctrine in Article 21, which provides: "Nothing in this Covenant shall be deemed to affect the validity of international engagements, such as treaties of arbitration or regional understandings like the Monroe Doctrine, for securing the maintenance of peace." Many in the United States did not consider this statement to be an adequate or accurate description of the doctrine, and one of the reservations which the Senate of the United States adopted in its discussion of the Treaty of Versailles declared the Monroe Doctrine "to be wholly outside the jurisdiction of said League of Nations and entirely unaffected by any provision contained in said treaty of peace with Germany" and reserved to the United States the sole right to interpret the doctrine. The treaty failed of ratification, and this reservation may be regarded as an expression of the opinion held by the majority of the members of the Senate. In

replying (Feb. 26, 1920) to a request of the minister of foreign affairs of Salvador for an interpretation of the Monroe Doctrine because of the bearing which such interpretation might have on the attitude of Salvador toward the Covenant, the acting secretary of State of the United States stated that the views of his Government were set forth in the address (Jan. 1916) of President Wilson before the Second Pan-American Scientific Congress. In the course of that address, President Wilson said that "the Monroe Doctrine demanded merely that European Governments should not attempt to extend their political systems to this side of the Atlantic." In Sept. 1928, the Council of the League of Nations, answering an inquiry by the Government of Costa Rica as to the interpretation placed by the League of Nations on the Monroe Doctrine, and the scope given to that doctrine when it was included in Article 21 of the Covenant, stated: "Article 20 stipulates that 'the Members of the League severally agree that this Covenant is accepted as abrogating all obligations or understandings *inter se* which are inconsistent with the terms thereof. . . .' Article 21 gives the States parties to international engagements the guarantee that the validity of such of these engagements as secure the maintenance of peace would not be affected by accession to the Covenant of the League of Nations. In declaring that such engagements are not deemed incompatible with any of the provisions of the Covenant, the Article refers only to the relations of the Covenant with such engagements; it neither weakens nor limits any of the safeguards provided in the Covenant. . . . In regard to the scope of the engagements to which the Article relates, it is clear that it cannot have the effect of giving them a sanction or validity which they did not previously possess. It confines itself to referring to these engagements, such as they may exist, without attempting to define them: an attempt at definition being, in fact, liable to have the effect of restricting or enlarging their sphere of application. Such a task was not one for the authors of the Covenant; it only concerns the States having accepted *inter se* engagements of this kind."

The Monroe Doctrine does not attempt to define in any other respects than those above mentioned the policies of the United States with respect to the other American republics. The construction of the Panama canal has not only established a new and convenient highway of commerce but has created new exigencies and new conditions of strategy and defence. It is the declared purpose of the United States to protect that highway. It is part of American policy not to yield to any foreign power the control of the Panama canal, or the approaches to it, or the obtaining of any position which would interfere with the right of protection on the part of the United States or would menace the freedom of its communications. This position is maintained equally with respect to American and non-American powers. The right asserted by the Government of the United States to afford protection to the lives and property of its nationals, when endangered in areas where governments have ceased properly to function, is maintained although there may be no prospect of non-American interference and no occasion for applying the Monroe Doctrine. Such interposition may have the actual and intended effect of avoiding the interposition of non-American powers and the consequent activities and developments at which the Monroe Doctrine was aimed, but the right of the United States to give appropriate protection to its nationals is regarded as quite distinct from the doctrine. The interest of the United States in the stability, the good order and the peace of its immediate neighbours, its efforts to promote amicable settlements of controversies, and its action under its treaties, may be based upon grounds independent of the Monroe Doctrine, although the success of such endeavours may have an indirect effect in making more remote the contingencies to which the doctrine would apply.

MONROVIA, a city of Los Angeles county, California, U.S.A., 18 m. N.E. of Los Angeles, in the foot-hills of the San Gabriel mountains. It is on the Federal highway 66 (the National Old Trail) and is served by the Pacific Electric, the Santa Fe and the Southern Pacific railways. Pop. (1920) 5,480; and 10,890 in 1930. The city is beautifully situated on a sloping plateau 750–1,400 ft. above sea-level, and is surrounded by orange groves. Fruit-packing is the principal industry. Monrovia was founded in 1886 by W. N. Monroe and was incorporated in 1887.

MONS, the capital of Hainaut province, Belgium. Pop. (1925) 28,085. The town originated probably in the Roman citadel Château-César. About 804 Charlemagne recognized it as the capital of Hainaut. At first the counts occupied the castle of Hornu, leaving Mons to the abbey and the church of St. Waudru. Regnier V. moved to Mons at the beginning of the 11th century, and his only child—a daughter—Richilde, married Baldwin VI. of Flanders. The two countdoms were again divided between Richilde's sons. At the beginning of the 14th century Mons was converted into a trading town by establishment of a cloth market. At the same time the count transferred his principal fortress from Valenciennes to Mons. When the Hainaut title became merged in the duchy of Burgundy, Mons was a stronghold near the French frontier. Its capture, defence and surrender by Louis of Nassau in 1572 and its many sieges in the 17th and 18th centuries attest its troubled history. Mons was converted into an open town in 1862.

The cathedral of St. Waudru, named after the first countess, was built 1450–1600 and contains some good glass as well as a few pictures by Van Thudden. The Hôtel de Ville is about the same age as the cathedral, having been commenced in 1443 and finished in 1467. The tower was added in 1718. There is also a fine belfry with a peal of bells. Mons is now a flourishing town with a good trade in cloth, lace, sugar refinery, etc.; but its chief importance is derived from its proximity to the Borinage (place of boring), district containing mines of the finest coal in Belgium. The military engineering college for the Belgian army is here, and not far from Mons are the battle-fields of Malplaquet (1709) and Jemappes (1792).

Battle of Mons, 1914.—This, the first battle of the British Expeditionary Force took place on Aug. 23, 1914, and next day the heavily outnumbered British army began the historic retreat which, marked by the Battle of Le Cateau (*q.v.*) ended on the Marne (*q.v.*), where the Franco-British counter-offensive turned the invasion. *See* World War: *Battles of the Frontier.*

MONSELICE, a town of Venetia, Italy, province of Padua, 15 m. S. of Padua by rail, 30 ft. above sea level. Pop. (1921) 4,143 (town), 14,243 (commune). It has some interesting buildings including a 13th century cathedral. The town is dominated by a rock crowned by a ruined castle (500 ft.) with five different lines of wall. Ca' Marcello is a fine battlemented palace (13th century) and the Villa Duodo a beautiful 18th century villa.

MONSIEUR, the general title of address in France used vocatively in speaking formally to any male person, like the English "sir" or prefixed to the name like the English "Mr." (Fr., formed from *mon*, my, and *sieur*, lord). It is, however, in France also prefixed to nobiliary, official and other titles; *e.g.*, *Monsieur le président*, *Monsieur le duc d'E.*, etc. It is abbreviated M., not

Mons. As a specific title "Monsieur" (*tout court*) was used from the time of Louis XIV. of the eldest brother of the king, as "Monseigneur" was of the dauphin; as a general title of address it was given to the princely members of a royal house.

MONSIGNOR, a title of honour granted by the pope to bishops and to high dignitaries and officials of the papal household (Italian, *monsignore,* my lord). It is abbreviated *Mgr.*

MONSIGNY, PIERRE ALEXANDRE (1729–1817), French composer, was born at Fauquembergue near St. Omer on Oct. 17, 1729. He received a classical education, and on his father's death went to work in an office in Paris. Through his family connections he became maître d'hôtel to the duke of Orleans and was presently in a financial position which enabled him to study music. His master Gianotti taught him harmony on the Ramean system. Monsigny had a remarkable gift of melody and his operas, though slight, were effectively written. His first, *Les aveux indiscrets,* produced at the *Théâtre de la Foire* in 1759, had an immediate success and he wrote 12 more during the next 18 years. Of these the most popular were *Rose et Colas* (1764) and *Felix, ou l'enfant trouvé* (1777), his greatest success. He lost his money and his employment in the revolution, but was afterwards given a pension and also a post at the conservatoire, from which he retired in 1802. He died on Jan. 14, 1817.

See Grove, *Dictionary of Music and Musicians;* A. Pougin, *Monsigny et son temps* (1908).

MONSOON, originally the name given by the Arabs to those seasonal winds of the Arabian sea which blow for approximately six months from the north-east and six months from the south-west. The name (Arabic *Mausim* or *Mawsim,* season), has been less correctly extended to seasonal winds in other parts of the world, *e.g.,* lower Mississippi States of North America; northern Australia; eastern central Africa. In India the term "monsoon" is specially used for the rain which falls during June to September with the onset of the south-west winds, hence a good monsoon means sufficient rainfall as contrasted with a deficiency for a bad monsoon. The total amount of rainfall bears little definite relation to the strength of the winds. The exact causes of the Asiatic monsoons cannot be conveniently summarized. The usual explanations are that in summer there is a high temperature and consequent low barometric pressure over the land with an indraft of sea air towards the interior, where it forms, or is formed by, great ascending air currents. G. C. Simpson points out that certainly as far as India is concerned the land is much hotter in May before the monsoon sets in than in July when it is at its height; again, the hottest part of India—the north-west—receives no rain during the wet monsoon and statistics prove that the average temperature is much greater in the years of bad monsoons than in the years of good monsoons.

The primary cause is certainly the difference of temperature over land and sea, and the south-west wind is a diverted south-east wind from the south of the Indian ocean which after some 4,000 miles journey is highly charged with water vapour and on reaching the north of India is caught in the box-like arrangement of the mountains. It is forced to rise and heavy rain results. For complete details of the Indian monsoon *see* G. C. Simpson "The South-West Monsoon." *Q.J.R. Met. Soc.* (1921).

MONSTER. In zoology, monsters form the subject of Animal Teratology, a department of morphology treating of deviations from the normal development of the embryo. In man, it is mostly in the first three months of intra-uterine life that those deviations from the normal occur which present themselves as monstrosities at the time of birth.

MONSTROSITIES IN A SINGLE BODY

The abnormality may extend to the body throughout, as in well proportioned giants and dwarfs; or it may affect a certain region or member, as when there is a finger or toe too many or too few. It is common for one malformation to be correlated with others, as in acardiac monsters, in which the non-development of the heart is associated with the non-development of the head, and with other radical defects.

Giants are conventionally limited to persons over 7ft. in height. The normal proportions of the frame are adhered to more or less closely, except in the skull, which is relatively small; but accurate measurements, even in the best proportioned cases, prove, when reduced to a scale, that other parts besides the skull—notably the thigh-bone and the foot—may be undersized though overgrown. The brain-case especially is undersized—the Irish giant in the museum of Trinity College, Dublin, is the single exception to this rule—but the bones of the face, and especially the lower jaw, are on a large scale. Giants are never born of gigantic parents; sterility usually goes with this monstrosity. Their size is sometimes excessive at birth, but more often the indications of great stature do not appear till later; they attain their full height before the twenty-first year.

FABULOUS MONSTERS OF GUIANA, NEAR LAKE PARIME. AFTER A DRAWING BY JOOST SAEGHMAN IN HIS COLLECTION OF VOYAGES, 1663

Dwarfs are conventionally limited to persons under 4ft. They are more likely than giants to have the modulus of the body perfect. Where disproportion occurs in the true dwarf it takes the form of a large-sized head, broad shoulders and capacious chest, and undersized lower limbs. Dwarfs with rickets and achondroplasia are perhaps to be distinguished from true dwarfs; these are cases in which the spine is curved, and sometimes the bones of the limbs bent and the pelvis deformed as the result of disease. As in the case of giants, dwarfs are seldom the progeny of dwarfs, who are usually sterile; the unnatural smallness may be obvious at birth, but is more likely to make itself manifest in the years of growth. Dwarfs are much more easily brought up than giants, and are stronger and longer-lived; they have usually also strong passions and acute intelligence. (*See* DWARF and GIANT.)

Redundancy and Defect in Single Parts.—The simplest case of redundancy is a sixth digit, well formed, and provided with muscles (or tendons), nerves and blood-vessels; it is usually a repetition of the little finger or toe, and may be present on one or both hands, or on one or both feet, or in all four extremities. The want of one, two or more digits is another simple anomaly; and, like redundancy, it is apt to repeat itself in the same family. Among the sense-organs there is a remarkable instance recorded of doubling of the appendages of the left eye, but not of the eyeball itself; the left half of the frontal bone is double, making two eye-sockets on that side, and the extra orbit has an eyebrow and eyelid. The external ear (*pinna*) has also been found double on one side and its orifice has frequently been found doubled in man and lower animals, and the additional ears lie in a definite relation to the branchial clefts of the embryo. Doubling of any of the internal organs or parts of organs may occur and innumerable cases have been recorded.

Defective Closure.—Imperfect closure along either of the embryonic lines of junction may produce various degrees of monstrosity. The simplest and commonest form is harelip with or without cleft palate, which results from defective closure of the ventral laminae at their extreme upper end. Another simple form (*spina bifida*) is a gap left in the neural canal at its lower end; usually the arches of the lumbar vertebrae are deficient, and the fluid that surrounds the spinal cord bulges out in its membranes, producing a soft tumour under the skin at the lower part of the back. More rarely the gap in the arches of the vertebrae is in the region of the neck. If it extend all along the back, it will probably involve the skull also. Deficiency of the crown of the head, and the spine as well, may be not always traceable to want of formative power to close the canal in the middle line; an over-distended condition of the central canal of the cord and brain may prevent the closure of the bones, and ultimately lead to the disruption of the nervous organs themselves; and injuries to the mother, with inflammation set up in the foetus and its appendages, may be the more remote cause. But it is by defect in the middle line that the mischief manifests itself, and it is

in that anatomical category that the malformations are included. The osseous deficiency at the crown of the head is usually accompanied by want of the scalp, brain and membranes.

Returning to the ventral middle line, there may be defects of closure in the breast-bone (fissure of the sternum), at the navel (the last point to close in any case), and along the middle line of the abdomen generally.

Hermaphroditism.—Strictly speaking, a hermaphrodite is a creature containing ovaries and testes. But in all the higher vertebrates, including man, the sex is predetermined in the fertilized ovum, and it is more than doubtful if true hermaphroditism occurs. On the other hand, in the majority of so-called hermaphrodites, there is much doubling and ambiguity in the secondary or external organs and parts of generation. Those parts which are rudimentary or obsolete in the male but highly developed in the female, and those parts which are rudimentary in the female but highly developed in the male tend in the hermaphrodite to be developed equally, and all of them badly.

Cyclops, Siren, etc.—The same feebleness of the formative energy which gives rise to defective closure in the middle line, and to ambiguous sex, leads also to imperfect separation of symmetrical parts. The most remarkable case of the kind is the cyclops monster. At a point corresponding to the root of the nose there is a single orbital cavity, sometimes small and with no eyeball, at other times of the usual size and containing an eyeball more or less complete. In still other cases the orbital cavity extends on each side of the middle line, and contains two eyeballs lying close together.

Another curious result of defective separation of symmetrical parts is the siren form of foetus, in which the lower limbs occur as a single tapering prolongation of the trunk like the hinder part of a dolphin, at the end of which a foot (or both feet) may or may not be visible.

Limbs Absent or Stunted.—Allied to these fused or unseparated states of the extremities is the class in which whole limbs are absent, or represented only by stumps. The trunk (and head) may be well formed, and the individual healthy; all four extremities may be reduced to short stumps either wanting hands and feet, or with the latter fairly well developed; or the legs only may be rudimentary or wanting, or the arms only, or one extremity.

Acardiac and Acranial Monsters.—It sometimes happens in a twin pregnancy that one of the embryos fails to develop a heart and complete vascular system of its own, depending for its nourishment upon blood derived from the placenta of its well-formed twin by means of its umbilical vessels. It grows into a shapeless mass, in which all traces of the human form may be lost.

Reversed Position of the Viscera.—This is a developmental error associated with the retention of the right aortic arch as in birds, instead of the left as is usual in mammals. The position of all the unsymmetrical viscera is transposed. This condition need cause no inconvenience; and it may remain undetected.

The causes of congenital anomalies are difficult to specify. There is no doubt that, in some cases, they are present in the sperm or germ of the parent; the same anomalies recur in several children of a family, and it has been found possible, through a variation of the circumstances, to trace the influence in some cases to the father alone, and in other cases to the mother alone. The remarkable thing in this parental influence is that the malformation in the child may not have been manifested in the body of either parent, or in the grandparents. More often the malformation is acquired by the foetus in the course of development and growth, either through the mother or in itself independently.

DOUBLE MONSTERS

Twins are the physiological analogy of double monsters, and some of the latter have come very near to being two separate individuals. The Siamese twins, who died in 1874 at the age of sixty, were joined only by a thick fleshy ligament from the lower end of the breast-bone (xiphoid cartilage), having the common navel on its lower border; the anatomical examination showed, however, that a process of peritoneum extended through the ligament from one abdominal cavity to the other, and that the blood-vessels of the two livers were in free communication across the same bridge. From double monstrosity, like the Siamese twins, there are all grades of fantastic fusion of two individuals into one down to the condition of a small body or fragment parasitic upon a well-grown infant—the condition known as *foetus in foetu*. These monstrosities may be deviations from the usual kind of twin gestation (one foetus being partially included within the body of the other) or from a rarer physiological type of dual development. In by far the majority of cases twins have separate uterine appendages, and have probably been developed from distinct ova; but in a small proportion of (recorded) cases there is evidence, in the placental and enclosing structures, that the twins had been developed from two rudiments which arise side by side on a single blastoderm. The perfect physiological type of this appears to be two rudiments on one blastoderm, whose entirely separate development produces twins (under their rarer circumstances), whose nearly separate development produces such double monsters as the Siamese twins, and whose less separate development produces the various forms of two individuals in one body.

Symmetrical Double Monsters are subdivided according to the part of the body where the fusion exists—head, thorax, umbilicus or pelvis. One of the simplest cases is a Janus head upon a single body, or there may be two pairs of arms with the two faces. Again, there may be one head with two necks and two complete trunks and pairs of extremities. Two distinct heads (with more or less of neck) may surmount a single trunk, broad at the shoulders but with only one pair of arms. The fusion, again, may be from the middle of the thorax downwards, giving two heads and two pairs of shoulders and arms, but only one trunk and one pair of legs. In another variety, the body may be double down to the waist, but the pelvis and lower limbs single. The degree of union in the region of the head, abdomen or pelvis may be so slight as to permit of two distinct organs or sets of organs in the respective cavities, or so great as to have the viscera in common; and there is hardly ever an intermediate condition between those extremes. Thus, in the Janus head there may be two brains, or only one brain. The pelvis is one of the commonest regions for double monsters to be joined at, and, as in the head and abdomen, the junction may be slight or total. The Hungarian sisters Helena and Judith (1701–23) were joined at the sacrum, but had the pelvic cavity and pelvic organs separate; the same condition obtained in the South Carolina negresses Millie and Christina, known as the "two-headed nightingale," and in the Bohemian sisters Rosalie and Josepha.

Unequal Double Monsters, Foetus in Foetu.—There are some well authenticated instances of this most curious of all anomalies. The most celebrated of these parasite-bearing monsters was a Genoese, Lazarus Johannes Baptista Colloredo, born in 1716, who was figured as a child by Licetus, and again by Bartholinus at the age of 28 as a young man of average stature. The parasite adhered to the lower end of his breastbone, and was a tolerably well-formed child, wanting only one leg; it breathed, slept at intervals, and moved its body, but it had no separate nutritive functions. The parasite is more apt to be a miniature acardiac and acephalous fragment, as in the case of the one borne in front of the abdomen of a Chinaman figured by I. Geoffroy St. Hilaire. Sometimes the parasite is contained in a pouch under the skin of the abdominal wall, and in another class (of which there is a specimen in the Hunterian museum) it has been included, by the closure of the ventral laminae, within the abdominal cavity of the foetus—a true *foetus in foetu*.

Monstrosities in man and animals have attracted attention since the earliest times, and amongst primitive and uncivilized peoples have been regarded as of supernatural origin. The human monstrosities were regarded as having been engendered in women by the devil either in his own form or in the guise of some animal. The belief still to be found amongst uneducated persons that unnatural union between women and male animals, or between men and female animals, may be fertile and produce monsters, is an attenuated form of the satanic legend. The scientific appreciation of monsters has grown with the study of embryology. William Harvey (1651) first referred monstrosities to their proper place as

abnormalities in embryonic reproduction. E. G. St. Hilaire was the first to attempt experimental teratology and to maintain that many monstrosities were the result of influences causing deviations from the normal course of embryonic development. I. G. St. Hilaire, his son, published an elaborate treatise on anomalies (Paris, 1832–37) which remains one of the most valuable records of the subject. A similar treatise with an incomparable atlas of illustrations was issued by W. Vrollik, the great Dutch anatomist, between 1840 and 1849, whilst A. Förster issued in 1861 a textbook with illustrations chiefly from preparations in the museum at Würzburg. The great museums devoted much attention to the collection and display of malformations, and there is a magnificent series in the Museum of the Royal College of Surgeons of England, with descriptive catalogues. In 1891 Camille Dareste published his experiments, chiefly on the developing egg of the fowl, not only showing the probable cause of many of the most common abnormalities, but practically creating a new branch of science, experimental embryology. Teratology has since become an off-shoot of embryology and heredity and must be studied in relation to these subjects.

E. Schwalbe's *Morphologie der Missbildungen* (1906–1909) is a very complete study of the modern developments of teratology, with a list of authorities from the earliest times. (C. Cr.; P. C. M.)

MONSTRANCE, a vessel used in the Roman Church for the exposition of the Host at Benediction (*q.v.*) and also when carried in processions. The earlier monstrances followed the usual shape of reliquaries, viz., a cylindrical crystal case mounted in metal frames, elaborately ornamented and jewelled. In the 16th century the present shape was adopted, viz., a crystal or glass circular disc, more suited to the shape of the sacred wafer.

MONSTRELET, ENGUERRAND DE (*c.* 1400–1453), French chronicler, belonged to a noble family of Picardy. He was for some time bailiff of the cathedral chapter and then provost of Cambrai. He died on July 20, 1453. Monstrelet was present, not at the capture of Joan of Arc, but at her subsequent interview with Philip the Good, duke of Burgundy. Continuing the work of Froissart, he wrote a *Chronique,* which extends to two books and covers the period between 1400 and 1444, when, according to another chronicler, Matthieu d'Escouchy, he ceased to write. A clumsy sequel, extending to 1516, was formed out of various chronicles and tacked on to his work. Monstrelet's own writings, dealing with the latter part of the Hundred Years' War, are valuable because they contain a large number of documents which are certainly, and reported speeches which are probably, authentic.

Among many editions of the *Chronique* may be mentioned the one edited for the *Société de l'histoire de France* by M. Douët d'Arcq (1857–62). *See* A. Molinier, *Les Sources de l'histoire de France,* tomes iv. and v. (1904).

MONTAGNA, BARTOLOMEO (1450–1523), Italian painter, the most eminent master of the school of Vicenza. He was a Brescian by birth. Vasari classes him among the pupils of Andrea Mantegna, but although there can be little doubt of the influence of the great Paduan master on his style, he more probably studied at Venice under the influence of Giovanni Bellini and Vittore Carpaccio. Montagna's style is dignified and austere, his form plastic, his colour exquisitely harmonious. He interpreted his favourite subject, "The Virgin and Child," either alone or attended by saints with a solemn, quiet grandeur. Montagna is first heard of at Vicenza in 1480; he also worked elsewhere, at Praglia near Padua and at Verona (1504–07) where he painted a fresco in the oratory of S. Biagio in the church of SS. Nazaro and Celso, as well as an altar-piece for the church of S. Sebastiano now in the Venice academy. His most important work is probably the great altar-piece of San Michele at Vicenza dated 1499, now in the Brera, Milan. Here the stateliness of the composition, staged under a lofty vault, the nobleness of the enthroned Madonna, the dignity of the attendant saints, the charm of the angels making music at the foot of the throne, are profoundly impressive. It would be impossible here to enumerate the numerous works of Montagna in Vicenza and in many public and private collections. One of his last pictures is the altar-piece, dated 1522, in the cathedral at Cologna Veneta. He died at Vicenza on Oct. 11, 1523. Bartolomeo founded a school of painting at Vicenza, from which sprang Giovanni Speranza, and partly also Giovanni Bonconsiglio and Francesco Ponte, the father of Jacopo Bassano.

His son, Benedetto Montagna (1470–1540), imitated the style of his father in his paintings. He was a distinguished engraver.

See T. Borenius, *The Painters of Vicenza* (1909).

MONTAGNAIS AND NASCAPEE. North of the St. Lawrence, the Montagnais and Nascapee resemble the southern Algonkin (*q.v.*) though their culture is affected by their unfavourable habitat. No crops are raised; they are hunters of caribou rather than fishers, chiefs have little authority, and no trace can be found of any political unit above the simple band. The canoe and wigwam of birch-bark are typical elements of culture, and the painted skin clothing of the Nascapee is distinctive. Life is unusually hard, material culture scanty, and women occupy an inferior place in the social scale.

MONTAGNANA, a town of Venetia, Italy, province of Padua, 30 m. S. of Vicenza by tramway. Pop. (1921), 7,871 (town); 12,151 (commune). It is entirely surrounded by mediaeval walls (1242–60) which are among the most perfect in Italy. The cathedral and S. Francesco are Romanesque-Gothic churches.

MONTAGU (*Family*). Dru of Montaigu or Montagud, the ancestor of the Montagus, earls of Salisbury, came to England with Robert, count of Mortain, half-brother of William the Conqueror. He is found in Domesday among the chief tenants of the count in Somerset, holding the manor of Shepton. This holding is represented in the return of 1166 by the ten knights' fee upon which his descendant, another Dru, is assessed. William Montagu of Shepton is among the knights summoned by Henry III. to the Gascon War and to the Welsh border in 1257. His son Simon, the first of the family to make a figure in history, followed Edward I. in 1277 and in 1282 against Llywelyn ap Gruffydd. In 1298 he was summoned as a baron; and in 1301, as Simon lord of Montagu, sealed the famous letter of the barons to the pope with his seal of the arms of Montagu, the counterseal showing a griffon. His son William (d. 1319), a favourite of Edward II., and seneschal of Aquitaine and Gascony, was succeeded by his eldest son, another William, who in 1330 secretly led the young king's partisans into Nottingham Castle, and carried off the earl of March.

In 1337 Montagu was created earl of Salisbury, and on the death of Thomas of Brotherton in 1338 was made marshal of England. His king employed him in missions to France, Scotland, Germany and Castile, and some time between 1340 and 1342 he led an expedition of his own against the Isle of Man, winning from the Scots the little kingdom to which he had inherited a claim through his grandfather Simon who had been granted the island by a certain Auffray or "Aufrica," who styled herself "Aufreca of Counnoght, heir of the land of Man." The first earl was succeeded in 1344 by William, his son and heir, who was one of the knights-founders of the Order of the Garter, fought at Crécy, and commanded the rearward battle at Poitiers. According to Froissart he attended the young Richard in Smithfield when the king faced the mob after the death of Wat Tyler. His only son was killed in 1383 at a tournament, and in 1393 the earl sold the lordship and crown of Man to William Scrope of Bolton. He was succeeded by his nephew John, the third earl (*c.* 1350–1400), son of Sir John Montagu by Margaret, the heir of the barons of Monthermer. The new earl was notorious as a Lollard, and was accused, after Henry IV.'s accession, of a share in Gloucester's death. He joined Kent, Huntingdon and Rutland in their plot against Henry, and was beheaded with the earl of Kent by the Cirencester mob. His son Thomas (1388–1428) was summoned as an earl in 1409, his father's dignities being restored to him in 1421, by which time his services at Harfleur and Agincourt had earned him French lordships, the lieutenant-generalship of Normandy and the earldom of Perche. He was killed at the famous siege of Orleans. His only daughter, Alice, married Richard Neville, a younger son of the first earl of Westmorland, who was allowed the earldom of Salisbury in right of his marriage. The famous "Richard-Make-a-King," earl of Warwick and Salisbury, was the grandson of the last of the Montagu earls.

MONTAGU, EDWIN SAMUEL (1879–1924), British politician, second son of the 1st Lord Swaythling (*q.v.*), was born on Feb. 6, 1879, and educated at the City of London School and at Trinity College, Cambridge. At Cambridge he was president of the Union and acquired a considerable reputation. When he entered parliament in 1906, as Liberal member for the Chesterton division of Cambridgeshire, he was chosen by Asquith, then Chancellor of the Exchequer, as his parliamentary secretary, and continued in that position when his chief succeeded to the premiership. Early in 1910 he was appointed under-secretary for India, under Lord Morley, and remained in the post, under Lord Crewe till 1914; and so made his first official acquaintance with India under the influence of Lord Morley's reforms and Lord Crewe's Durbar changes of 1911. As both his chiefs were in the Lords, he was the spokesman of the office in the Commons. He went out to India during his tenure of office to see things for himself.

After holding during the World War the posts of financial secretary to the treasury, chancellor of the duchy of Lancaster (1915) and minister of munitions (1916), he returned in 1917 to the India Office as secretary of state and began a tenure of that post which will always be memorable in Indian annals.

He visited India in the following winter for the second time, and held prolonged conferences with the viceroy, Lord Chelmsford, the leading members of the Indian Civil Service, ruling princes and native politicians, and, with the viceroy, received deputations and memoranda from all classes. Ultimately in July 1918 there was published an elaborate report, signed by the viceroy as well as by the secretary of state, recommending a series of constitutional reforms which should give the Indian peoples in time to come a large and real share in their own government. In December 1919 he had the satisfaction of passing through parliament the Government of India bill, which established in India, in accordance with the report, what was called a "dyarchy," a partition of the powers of Government between the civil service and the native population. For events in India which followed *see* India: *History*.

In March 1922 Montagu had to resign his office for having published, without the authority of the cabinet, a telegram from the Government of India urging a more friendly policy towards Turkey. He defended his action by maintaining that cabinet responsibility had been destroyed by Lloyd George's dictatorial methods. At the general election of 1922 he lost his seat in Parliament, and went into the city, becoming vice-chairman of the De Beers Co. He had married in 1915 Beatrice Venetia, youngest daughter of the 4th Baron Sheffield, and he died in London on Nov. 15, 1924.

MONTAGU, ELIZABETH ROBINSON (1720–1800), English leader of society, was born at York on Oct. 2, 1720. In 1742 she married Charles Montagu, cousin of Edward Wortley Montagu and son of the earl of Sandwich. Thanks to her, his Mayfair house became the social centre of intellectual society in London, and her breakfast parties and evening conversaziones gained her the title of "The Madame du Deffand of the English capital." In other quarters the term "blue-stocking" was applied to her guests. From her husband, who died in 1775, she inherited a considerable fortune and large estates. In 1781 she built Sandleford Priory, near Newbury, and Montagu House, now 22 Portman Square, London, the latter from designs by James Stuart. She died on Aug. 25, 1800. There is an admirable portrait of her by Reynolds.

See *Elizabeth Montagu, the Queen of the Blue Stockings: Her Correspondence from 1720 to 1761* (ed. E. J. Climenson, 2 vols., 1906); R. Huchon, *Mrs. Montagu and her Friends, 1720–1800* (Eng. trans., 1907); and *Mrs. Montagu, Queen of the Blues* (ed. R. Blunt, a continuation of E. J. Climenson's book, 2 vols., 1923).

MONTAGU, LADY MARY WORTLEY (1689–1762), English letter-writer, eldest daughter of Evelyn Pierrepont, afterwards duke of Kingston, was baptized at Covent Garden on May 26, 1689. Her mother, who died while her daughter was still a child, was a daughter of William Feilding, earl of Denbigh. Her father was proud of her beauty and wit, and when she was eight years old she is said to have been the toast of the Kit-Kat Club. He took small pains with the education of his children, but Lady Mary was encouraged in her self-imposed studies by her uncle, William Feilding, and by Bishop Burnet. She formed a close friendship, and carried on an animated correspondence with Mary Astell, who was a champion of woman's rights, and with Anne Wortley Montagu, grand-daughter of the first earl of Sandwich. The letters on Anne's side, however, were often copied from drafts written by her brother, Edward Wortley Montagu, and after Anne's death in 1709 the correspondence between him and Lady Mary was prosecuted without an intermediary. Lady Mary's father, now marquess of Dorchester, declined, however, to accept Montagu as a son-in-law because he refused to entail his estate on a possible heir. Negotiations were broken off, and when the marquess insisted on another marriage for his daughter the pair eloped (1712).

The early years of Lady Mary Wortley Montagu's married life were spent in rigid economy and retirement in the country. Her husband was M.P. for Westminster in 1715, and shortly afterwards was made a commissioner of the treasury. When Lady Mary joined him in London her wit and beauty soon made her a prominent figure at court. Early in 1716 Montagu was appointed ambassador at Constantinople. Lady Mary accompanied him to Vienna, and thence to Adrianople and Constantinople. He was recalled in 1717, but they remained at Constantinople until 1718. The story of this voyage and of her observations of Eastern life is told in a series of lively letters full of graphic description. From Turkey she brought back the practice of inoculation for small-pox. She had her own children inoculated, and encountered a vast amount of prejudice in bringing the matter forward.

Before starting for the East she had made the acquaintance of Alexander Pope, and during her absence he addressed to her a series of extravagant letters, which appear to have been chiefly exercises in the art of writing gallant epistles. Very few letters passed after Lady Mary's return, and various reasons have been suggested for the subsequent estrangement and violent quarrel and the *Verses addressed to an Imitator of Horace*. Lady Mary always professed complete innocence. The reason was possibly that Pope had made love to her and been received with laughter. In any case, Pope attacked her again and again with the grossest insults, and her chief ally, Lord Hervey, as well. In return she is credited with a hand in *A Pop upon Pope*. She had a romantic correspondence with a Frenchman named Rémond, who addressed to her a series of excessively gallant letters before ever seeing her. She invested money for him in South Sea stock at his desire, and, as was expressly stated, at his own risk. The value fell to half the price, and he tried to extort the original sum as a debt by a threat of exposing the correspondence to her husband. This disposes of the second half of Pope's line "Who starves a sister, or forswears a debt" (*Epilogue to the Satires*, i. 113), and the first charge is quite devoid of foundation.

In 1739 she went abroad, and although she continued to write to her husband in terms of affection and respect they never met again. At Florence in 1740 she visited Horace Walpole, who cherished a great spite against her, and exaggerated her eccentricities into a revolting slovenliness. (See *Letters*, ed. Cunningham, i. 59.) She lived at Avignon, at Brescia, and at Lovere, on the Lago d'Iseo. She was disfigured by a painful skin disease, and her sufferings were so acute that she hints at the possibility of madness. She was struck with a terrible "fit of sickness" while visiting the countess Palazzo and her son, and perhaps her mental condition made restraint necessary. As Lady Mary was then in her sixty-third year, the scandalous interpretation put on the matter by Horace Walpole may safely be discarded. Her husband spent his last years in hoarding money, and at his death in 1761 is said to have been a millionaire. His extreme parsimony

is satirized in Pope's *Imitations of Horace* (2nd satire of the 2nd book) in the portrait of Avidieu and his wife. Her daughter Mary, countess of Bute, whose husband was now prime minister, begged her to return to England. She came to London, and died in the year of her return, on Aug. 21, 1762. The general opinion of her was that as a letter-writer she was second only to Mme. de Sévigné. However that may be, there could hardly be two people more unlike. Lady Mary's letters are vivid, downright and scandalous; their interest lies not so much in the works as in the scenes and incidents of her wandering life.

Her son, EDWARD WORTLEY MONTAGU (1713–1776), author and traveller, inherited something of his mother's gift and more than her eccentricity. He was born in May 1713, twice ran away from Winchester School, and the second time made his way as far as Oporto. He was then sent to travel with a tutor in the West Indies, and afterwards with a keeper to Holland. He made, however, a serious study of Arabic at Leyden (1741), and returned twenty years later to prosecute his studies. His father made him a meagre allowance, and he was heavily encumbered with debt. He was M.P. for Huntingdon in 1747, and was one of the secretaries at the conference of Aix-la-Chapelle. In 1751 he was involved in a disreputable gaming quarrel in Paris, and was imprisoned for eleven days in the Châtelet. He continued to sit in parliament, and wrote *Reflections on the Rise and Fall of the Antient Republics* . . . (1759). His father left him an annuity of £1,000, the bulk of the property going to Lady Bute. He set out for extended travel in the East, lived at Venice and died at Padua on April 29, 1776.

Lady Mary's "Town Eclogues" were published in a pirated edition as *Court Poems* in 1716. Of her famous *Letters* from the East she made a copy shortly after her return to England. She gave the MS. to Benjamin Sowden, a clergyman of Rotterdam, in 1761. After Lady Mary's death this was recovered by the earl of Bute, but meanwhile an unauthenticated edition, supposed to have been prepared by John Cleland, appeared (1763), and an additional volume, probably spurious, was printed in 1767. The rest of the correspondence printed by Lord Wharncliffe in the edition of her letters is edited from originals in the Wortley collection. This edition (1837) contained "Introductory Anecdotes" by Lady Bute's daughter, Lady Louisa Stuart. A more critical edition of the text, with the "Anecdotes," and a "Memoir" by W. Moy Thomas, appeared in 1861. A selection of the letters arranged to give a continuous account of her life, by Mr. A. R. Ropes, was published in 1892; and another by R. Brimley Johnson in "Everyman's Library" in 1906. *See* also George Paston, *Lady Mary Wortley Montagu and her Times* (1907), which contains some hitherto unpublished letters. Lady Mary's journal was preserved by her daughter, Lady Bute, till shortly before her death, when she burnt it. There is a full and amusing account of Edward Wortley Montagu in Nichols's *Anecdotes of Literature*, iv. 625–656; L. Melville, *Lady Mary Wortley Montagu* (1925); Iris Barry, *Portrait of Lady Mary Wortley Montagu* (1928).

MONTAGU, RALPH, 1ST DUKE OF (*c.* 1638–1709), English diplomatist, was the second son of Edward, 2nd Baron Montagu of Boughton (1616–84), whose peerage was one of several granted in the 17th century to different members of the Montagu family (*q.v.*). Appointed master of the horse to Queen Catherine, wife of Charles II., he soon acquired a reputation for gallantry at the court. He took an active part in the negotiations in which Louis XIV. purchased the neutrality of England in the war between France and Holland. In 1678 he was elected member of parliament for Northampton, but on the dissolution of parliament attempted unsuccessfully to fly to France. He supported the movement for excluding the duke of York from the succession and for recognizing Monmouth as heir. His elder brother having predeceased his father, Ralph became Baron Montagu of Boughton on the death of the latter in 1684. Notwithstanding his former intrigues he gained the favour of James II. on his accession to the throne, but this did not deter him from welcoming William of Orange, who created him Viscount Monthermer and earl of Montagu in 1689. His position was further strengthened in 1705 by the marriage of his son to Mary, daughter of the great duke of Marlborough. In the same year he was raised to the dukedom as duke of Montagu and marquess of Monthermer. He died on March 9, 1709. His London residence, Montagu House, Bloomsbury, was bought by the government in 1753 to hold the national collection of antiquities, and on its site was built the British Museum. At the death of his son John in 1749, the title became extinct.

See A. Boyer, *History of the Reign of Queen Anne*, vol. viii. (1703–13); Burke, *Genealogical History of Dormant* (etc.) *Peerages* (1883); and article in *Dict. Nat. Biog.*

MONTAGU (or MOUNTAGUE), **RICHARD** (1577–1641), English divine, was born at Dorney, Buckinghamshire, and educated at Eton and King's college, Cambridge. He was appointed to the deanery of Hereford in 1616, but exchanged it next year for a canonry of Windsor, which he held with the rectory of Petworth, Sussex. He was also chaplain to James I. Like Laud, he disliked the extremes of Calvinism and Romanism. About 1619 he came into collision with some Roman Catholics in his parish, and Matthew Kellison (1560?–1642) attacked him in a pamphlet entitled *The Gagg of the Reformed Gospell* (Douai, 1623). Montagu replied with *A Gagg for the New Gospell? No. A New Gagg for an Old Goose* (1624). The publication of the *Immediate Addresse unto God alone* (1624) incensed the Puritans, who appealed to the House of Commons, but Montagu was protected by the king. After the appearance of his famous *Appello Caesarem* (1625), in which he vindicated himself from the divergent charges of Arianism and popery, his case frequently came before parliament and conferences of bishops, but his influence at court and with Laud saved him. He was consecrated bishop of Chichester in 1628, and became bishop of Norwich in 1638. He died on April 13, 1641.

MONTAIGNE, MICHEL DE (1533–1592), French essayist, was born, as he himself tells us, between eleven o'clock and noon on Feb. 28, 1533. The patronymic of the Montaigne family, who derived their title from the château at which the essayist was born and which had been bought by his grandfather, was Eyquem. Montaigne is not far from Bordeaux, with which the Eyquem family had for some time been connected. Pierre Eyquem, Montaigne's father, had been engaged in commerce (a herring-merchant Scaliger calls him, and his grandfather Ramon had certainly followed that trade), had filled many municipal offices in Bordeaux, and had served under Francis I. in Italy as a soldier. He married Antoinette de Louppes (Lopez), descended from a family of Spanish Jews. The essayist was the third son. By the death of his elder brothers, however, he became head of the family. He had also six younger brothers and sisters. Montaigne was put out to nurse with a peasant woman, and had his sponsors from the same class. He was taught Latin orally by servants who could speak no French, and many curious fancies were tried on him, as, for instance, that of waking him every morning by soft music.

At six years old Montaigne was sent to the collège de Guienne at Bordeaux, then at the height of its reputation. At thirteen Montaigne began to study law, probably at Toulouse. In 1548 he was at Bordeaux during one of the frequent riots caused by the gabelle, or salt-tax. Six years afterwards he was made a counsellor in the Bordeaux parlement. In 1558 he was present at the siege of Thionville, in 1559 and 1561 at Paris, and in 1562 at the siege of Rouen. He was also much about the court, and he admits that in his youth he led a life of pleasure, if not exactly of excess.

In 1565 Montaigne married Françoise de la Chassaigne, whose father was, like himself, a member of the Bordeaux parlement. Three years later his father died, and he succeeded to the family possessions. Finally, in 1571, he retired to Montaigne, having given up his magistracy the year before. His health, never strong, had been further weakened by hard living. He resolved, accordingly, to retire to a life of study and contemplation, though he indulged in no asceticism except careful diet. He lived on excellent terms with his wife, and bestowed some pains on the education of the only child (a daughter Léonore) who survived infancy.

THE ESSAYS

In his father's lifetime, and at his request, he had translated the *Theologia naturalis* of Raymund de Sabunde, a Spanish schoolman (published 1569). On first coming to live at Montaigne he edited the works of his deceased friend Étienne de la Boétie. But the years of his studious retirement were spent on a work

of infinitely greater importance. Garrulous after a fashion as Montaigne is, he gives us no clear idea of any original or definite impulse leading him to write the famous *Essays*. It is very probable that if they were at first intended to have any special form at all it was that of a table-book or journal. The earlier essays, those of the first two books, differ from the later in one most striking point, in that of length. Speaking generally, the essays of the third book average fully four times the length of those of the other two. This of itself would suggest a difference in the system of composition. These first two books appeared in 1580, when their author was 47 years old.

They contain, as at present published, no fewer than ninety-three essays, besides an exceedingly long apology for the already mentioned Raymund Sabunde, in which some have seen the kernel of Montaigne's philosophy. The book begins with a short *avis* (address to the reader), opening with the well-known words, *"C'est icy un livre de bon foy, lecteur,"* and sketching in a few lively sentences the character of meditative egotism which is kept up throughout. His sole object, he says, is to leave for his friends and relations a mental portrait of himself, defects and all; he cares neither for utility nor for fame. The essays then begin, without any attempt to explain or classify their subjects. Their titles are of the most diverse character. Sometimes they are proverbial sayings or moral adages, such as "Par divers moyens on arrive à pareille fin," "Qu'il ne faut juger de notre heur qu'après la mort," "Le profit de l'on est le dommage de l'aultre." Sometimes they are headed like the chapters of a treatise on ethics: "De la tristesse," "De l'oisiveté," "De la peur," "De l'amitié." Sometimes a fact of some sort which has awaked a train of associations in the mind of the writer serves as a title, such as "On est puni de s'opiniastrer à une place sans raison," "De la bataille de Dreux," etc. Occasionally the titles seem to be deliberately fantastic, as "Des puces," "De l'usage de se vestir." Sometimes, though not very often, the sections are in no proper sense essays, but merely commonplace book entries of singular facts or quotations, with hardly any comment.

In 1571 he had received the order of Saint-Michel; in 1574 was with the army of the duke de Montpensier; two years later was made gentleman-in-ordinary to Henry III., and next year again to Henry of Navarre. He visited Paris occasionally, and travelled for health or pleasure to Cauterets, Eaux Chaudes and elsewhere. But his health grew worse and worse, and he was tormented by stone and gravel. He accordingly resolved to journey to the baths of Lucca. Late in the 18th century a journal found in the château of Montaigne, giving an account of this journey, was published in 1774; part of it is written in Italian and part dictated in French, the latter being for the most part the work of a secretary or servant. The ms. disappeared early, and the work is almost destitute of literary interest. At Rome he received news of his election as mayor of Bordeaux with a peremptory royal endorsement enjoining residence, and after some time journeyed homewards.

The memory of his father, however, and the commands of the king induced Montaigne to accept the mayoralty; and he seems to have discharged it neither better nor worse than an average magistrate. He was re-elected at the close of his term. His second term of office terminated in 1585; and in 1588 after a visit of some length to Paris, the third book of the *Essays* was published, together with the former ones considerably revised. The new essays, as has been remarked, differ strikingly from the older ones in respect of length; and the whimsical unexpectedness of the titles reappears in but two of them: "Des Coches" and "Des Boiteux." They are, however, identical with the earlier ones in spirit, and make with them a harmonious whole—a book which has hardly been second in influence to any of the modern world.

HIS POSITION IN LITERATURE

This influence is almost equally remarkable in point of matter and in point of form. Montaigne is one of the few great writers who have invented a literary kind. The essay as he gave it had no forerunner in modern literature and no direct ancestor in the literature of classical times. In matter of style and language Montaigne's position is equally important, but the ways which led him to it are more clearly traceable. His favourite author was beyond all doubt Plutarch, and his own explicit confession makes it undeniable that Plutarch's translator, Jacques Amyot, was his master in point of vocabulary and (so far as he took any lessons in it) of style. Montaigne, however, followed with the perfect independence that characterized him. He was a contemporary of Ronsard, and his first essays were published when the innovations of the Pléiade had fully established themselves. He adopted them to a great extent, but with much discrimination, and he used his own judgment in latinizing when he pleased. In the same way he retained archaic and provincial words with a good deal of freedom, but by no means to excess.

Perhaps the only actual parallel to Montaigne in literature is Lamb. There are differences between them, arising naturally enough from differences of temperament and experience; but both agree in their attitude—an attitude which is sceptical without being negative and humorous without being satiric. There is hardly any writer in whom the human comedy is treated with such completeness as it is in Montaigne. There is discernible in his essays no attempt to map out a complete plan, and then to fill up its outlines. But in the desultory and haphazard fashion which distinguishes him there are few parts of life on which he does not touch, if only to show the eternal contrast and antithesis which dominate it. The exceptions are chiefly to be found in the higher and more poetical strains of feeling to which the humorist temperament lends itself with reluctance and distrust, though it by no means excludes them. The positiveness of the French disposition is already noticeable in Rabelais; it becomes more noticeable in Montaigne. He is always charming, but rarely inspiring.

Montaigne did not very long survive the completion of his book. On his way to Paris for the purpose of getting it printed he stayed for some time at Blois, where he met De Thou. In Paris itself he was for a short time committed to the Bastille by the Leaguers, as a kind of hostage, it is said, for a member of their party who had been arrested at Rouen by Henry of Navarre. But he was well known to and favoured by both Catherine de' Medici and the Guises, and was very soon released. In Paris, too, at this time he made a whimsical but pleasant friendship with Marie de Jars de Gournay (1565–1645), one of the most learned ladies of the 16th and 17th centuries, who became his "fille d'alliance" (adopted daughter), a title which she bore for the rest of her long life. When Henry of Navarre came to the throne of France, he wished Montaigne, whom he had visited in 1584 and 1587, to come to court, but this was refused. It would seem that he returned from Paris to his old life of study and meditation and working up his *Essays*. No new ones were found after his death, but many alterations and insertions. He was attacked with quinsy, which brought about paralysis of the tongue, and he died on Sept. 13, 1592. He was buried, though not till some months after his death, in a church in Bordeaux, which after some vicissitudes became the chapel of the collège.

When Mlle. de Gournay heard of the death of Montaigne she undertook with her mother a visit of ceremony and condolence to the widow, which had important results for literature. Mme. de Montaigne gave her a copy of the edition of 1588 annotated copiously; at the same time, apparently, she bestowed another copy, also annotated by the author, on the convent of the Feuillants in Bordeaux, to which the church in which his remains lay was attached. Mlle. de Gournay thereupon set to work to produce a new and final edition with a zeal and energy which would have done credit to any editor of any date. She herself worked with her own copy, inserting the additions, marking the alterations and translating all the quotations. But when she had got this to press she sent the proofs to Bordeaux, where a poet of some note, Pierre de Brach, revised them with the other annotated copy. The edition thus produced in 1595 has with justice passed as the standard, even in preference to those which appeared in the author's lifetime.

Unluckily, Mlle. de Gournay's original does not appear to exist and her text was said, until the appearance of MM. Courbet and Royer's edition, to have been somewhat wantonly corrupted, especially in the important point of spelling. The Feuillants copy is in existence, being the only manuscript, or partly manuscript, authority for the text. This manuscript was edited in 1803 by Naigeon, the disciple of Diderot; but, according to later inquiries, considerable liberties were taken with it. The first edition of 1580, with the various readings of two others which appeared during the author's

lifetime, was reprinted by MM. Dezeimeris and Burckhausen in 1870. That of Le Clerc (3 vols., 1826–28) and in a more compact form that of Louandre (4 vols., 1854) have been most useful; but that of MM. Courbet and Royer (1872–1900) is at present the standard; a more recent edition is by P. Villey (1922). The *Journal,* long neglected and still (*vide supra*) doubtful, was re-edited by Professor A. d'Ancona (Città di Castello, 1895) and translated into English by W. G. Waters (1903). The *Oeuvres complètes* were edited by A. Armaingaud in 1924. Modern books of importance are P. Bonnefon's *Montaigne, l'homme et l'oeuvre* (1893) and P. Stapfer's *Montaigne* (1895) in the *Grands écrivains,* the latter a book of remarkable excellence. Edmé Champion's *Introduction aux essais* may also be noticed, and Professor Dowden's *Montaigne* (1905), which has an excellent bibliography. The somewhat earlier *Montaigne* of M. E. Lowndes (Cambridge, 1898) is noteworthy in especial for its attention to his life and character.

In England Montaigne was early popular. It was long supposed that the autograph of Shakespeare in a copy of Florio's translation showed his study of the *Essays.* The autograph has been disputed, but divers passages, and especially one in *The Tempest,* show that at first or second hand the poet was acquainted with the essayist. The book best worth consulting on this head is J. Feis's *Shakespeare and Montaigne* (1884). Towards the latter end of the 17th century, Cotton, the friend of Izaak Walton, executed a complete translation, which, though not extraordinarily faithful, possesses a good deal of rough vigour. It has been frequently reprinted with additions and alterations; W. C. Hazlitt's edition (1892) was reprinted in 1923. Reprints of Florio are also numerous. One in the "Tudor Translations" (1893) has an introduction by G. Saintsbury; a recent translation of the essays is by E. J. Trechmann (2 vols., 1927). An English biography of Montaigne by Bayle St. John appeared in 1858, and Walter Pater's unfinished *Gaston de Latour* borrows from Montaigne and his story. The most noteworthy critical handling of the subject in English is unquestionably Emerson's in *Representative Men. See* also E. Sichel, *Michel de Montaigne* (1911); J. Prevost, *La Vie de Montaigne* (1926).

MONTALEMBERT, CHARLES FORBES RENÉ DE (1810–1870), French publicist, historian, and academician (1851), was born on March 15, 1810. Montalembert's father, Marc René, emigrated, fought under Condé, and subsequently served in the English army; he married Elise Rosée Forbes, and his eldest son, Charles, was born in London. At the Restoration of 1814 Marc René returned to France, was raised to the peerage in 1819, and became ambassador to Sweden (where Charles completed his education) in 1826. He died in 1831, a year after the overthrow of the legitimate monarchy. Charles de Montalembert was a Liberal, in the English sense, but was unable to support the Government of Louis Philippe on religious grounds. He wished to see the Church free from the control of the State, and passionately attacked the monopoly of public instruction by which the monarchy fortified its position. Montalembert was formally charged with unlicensed teaching. He claimed the right of trial by his peers, and made a notable defence (1832). On the other hand, he thought that the Church should not obstinately oppose new ideas. He collaborated with his friends, Lamennais and Lacordaire, in the newspaper *l'Avenir.* The Ultramontane party was roused by their boldness, and Montalembert and his two friends then left for Rome. This famous pilgrimage proved useless to mitigate the measures which the Roman curia took against the *Avenir.* Its doctrines were condemned in two encyclicals (*Mirari vos,* 1832, and *Singulari vobis,* 1834), and Montalembert submitted. After the revolution of 1848 he sat in the Chamber of Deputies till 1857. He was recognized as one of the most formidable opponents of the empire. Meanwhile his Liberal ideas had made him irreconcilable enemies among the Ultramontanes, notably Louis Veuillot, editor of *L'Univers.* Montalembert answered his attacks by reviving the *Correspondant* (1855), in which he opposed both the fanatical party of Pius IX. and the *Syllabus,* and the more or less free-thinking Liberals of the *Revue des deux mondes.* After the promulgation by the Vatican council of the dogma of papal infallibility he would not allow himself to be seduced from obedience to the pope; he now severed his connection with Père Hyacinthe (Loison) as he had with Lamennais, and made the submission expected of him to the council. He died on March 13, 1870.

Montalembert's first historical work, *La Vie de Ste Elisabeth de Hongrie* (1836), is not so much a history as a religious manifesto. His studies of monarchism in the West bore fruit in his *Moines d'occident* (1860), which was unfinished at the time of the author's death, but was completed later from some long fragments found among his papers (vols. vi. and vii., 1877).

Bibliography.—Mrs. Oliphant, *Memoir of Count de Montalembert, peer of France, deputy for the department of Doubs* (1872). Mrs. Oliphant also translated into English the work *Moines d'occident. See* also the vicomte de Meaux, *Montalembert* (1897); L. R. P. Lecanuet, *Montalembert, d'après son journal et sa correspondance* (3 vols., 1895–1902), a work filled with important documents; Léon Lefébvre, *Portraits de croyants au XIX^e siècle: Montalembert, Auguste Cochin, François Rio* (who was Montalembert's professor of philosophy), *A. Guthlin* (1905); and *Lettres d'Alphonse d'Herbelot à Charles de Montalembert et à Léon Cornudet* (1828–30).

MONTALEMBERT, MARC RENÉ, Marquis de (1714–1800), French military engineer and writer, was born at Angoulême on July 16, 1714, and entered the French army in 1732. He fought in the War of the Polish Succession on the Rhine (1733–34), and in the War of the Austrian Succession made the campaigns of 1742 in Bohemia and Italy. In the years preceding the Seven Years' War, Montalembert devoted his energies to the art of fortification, to which Vauban's *Traité de l'attaque* attracted him, and founded the arsenal at Ruelle, near his birthplace. On the outbreak of war he became French commissioner with the allied army of Sweden, with the rank of brigadier-general. He constructed the field fortifications of Anklam and Stralsund. In 1761 he was promoted *maréchal de camp,* and began the works on which his fame rests. Montalembert's fortress has been aptly described by an English author as an "immense battery." The intricacies of trace by which Vauban and Cormontaigne sought to minimize the power of the attack are abandoned in favour of a simple tenaille plan so arranged that the defenders can bring an overwhelming fire to bear on the works of the besieger.

Montalembert, who himself drew his idea from the practice of Swedish and Prussian engineers, furnished the German constructors of the early 19th century with the means of designing entrenched camps suitable to modern conditions of warfare. The "polygonal" method of fortification is the direct outcome of Montalembert's systems. In his own country the caste-spirit of the engineer corps was roused to defend Vauban, and though Montalembert was allowed to construct some successful works at Aix and Oléron, he was forbidden to publish his method, and given but little opportunity for actual building. After fifteen years of secrecy he published in Paris (1776–1778) the first edition of *La Fortification perpendiculaire.* At the time of the Revolution he emigrated for a time. After his return Carnot often called him into consultation on military affairs, and, in 1792, promoted him general of division. He died in Paris on March 29, 1800. His wife, Marie Josephine de Comarieu, was the hostess of one of the best-known *salons* of Louis XVI.'s time. He withdrew his candidature to the *Institut* in favour of General Buonaparte.

Besides his masterpiece, he wrote *L'Art défensive supérieure à l'offensif* (1793; in reply to attacks made upon his earliest work, *La Fortification perpendiculaire,* of which in later editions it forms part); *Mémoire historique sur le fonte des canons* (Paris, 1758), and other works on the same subject; *Correspondance pendant la guerre de 1757–1760* (London, 1777); *Rotation des boulets* (Acad., 1755); and *Rélations du siège de S. Jean d'Acre* (Paris, 1789). *See* Tripier, *La Fortification déduite de son histoire* (Paris, 1866).

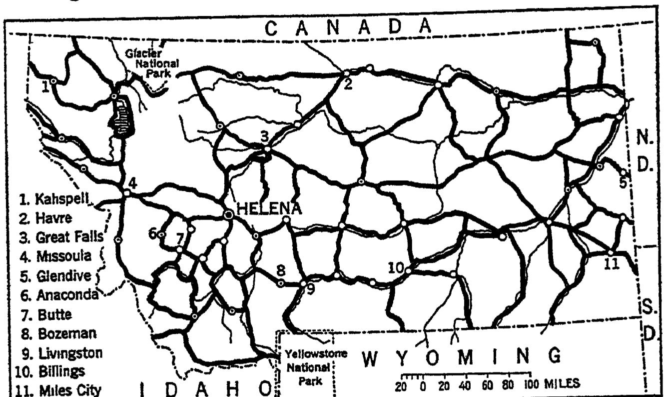
MONTANA (5,120 ft.), a village in the canton of Valais, Switzerland, at the south foot of the Bernese Alps. It is connected with Sierre (on the Simplon line) by a funicular railway. It is a health resort and tourist centre and has 791 inhabitants.

MONTANA, the "Treasure State," is situated in the north-western part of the United States of America between lat. 44° 26′ and 49° N. and long. 104° and 116° W. of Greenwich. It is bounded north by the Canadian provinces of British Columbia, Alberta and Saskatchewan; east by North Dakota and South Dakota; south by Wyoming and Idaho; west by Idaho. In size it ranks third among the States of the Union, having a land area of 146,131 sq.m. and a water area of 866 sq. miles. Its greatest length is 556 m., and its width is about one-half as much. The Territory was organized in 1864, and admitted to the Union in 1889. Its name, given to it by James M. Ashley, who sponsored the bill for its territorial organization, means "mountainous regions."

Physical Features.—The Rocky Mountains cross the State from north-west to south-east, and with their spurs and outlying ranges occupy two-fifths of its area in the west and south-west;

the remaining portion is occupied chiefly by the Great Plains. The continental divide follows the boundary line between Montana and Idaho west and north-west from Yellowstone Park in Wyoming to Ravalli county, then turns southeast through Deer Lodge and Silver Bow counties, then northward to Lewis and Clark county, and from there extends north-north-west into Canada.

The great Bitter Root range of mountains, formed by a great



MAP SHOWING THE MAIN ROADS OF MONTANA

fault, rises abruptly from the Bitter Root basin, and between its long rocky ridges with peaked or saw-toothed crest lines glaciers have cut canyons with high and often precipitous walls. North beyond the Bitter Root mountains is the Cabinet range, and in the extreme north-west are the Kootenai mountains. East of Flathead lake the Mission range rises sheer from the valley floor to sharp magnificent peaks. Between these ranges are broad valleys whose waters flow by the Clark's fork of the Columbia to the Pacific ocean. The north branch of the Clark's fork, the Flathead river, gathers its waters from the Swan and Mission ranges and the western slope of the main range, and flowing south through Flathead lake, the largest in the State, joins the Missoula in Paradise valley to form the Clark's fork. The Missoula comes from the south-east, where, near the town of Missoula, it is formed by the union of the Bitter Root, draining the Bitter Root valley from the south, and the Hell Gate coming down through Hell Gate pass from Deer Lodge valley to the eastward. Through the latter valley the transcontinental lines of the Northern Pacific and Chicago, Milwaukee and St. Paul railways are built. The continental divide contains peaks more than 10,000 ft. in altitude, but in general it is low, with several passes less than 6,000 feet. Along this divide, just south of the Canadian border, and embracing spurs of the divide with a total area of 915,000 ac., is Glacier National park, containing some of the most rugged scenery in the United States. Deep between the precipitous mountains are long, narrow mountain lakes, fed by glaciers hung on the shoulders of the peaks above them. The State also contains one of the favourite entrances to Yellowstone Park. Just north of Yellowstone Park are the Absarokas and Beartooth ranges, the latter containing Granite peak (12,850 ft.), the highest elevation in the State.

The Great Plains slope from about 4,000 ft. above the sea at the foothills of the mountains to 2,000 ft. in the north-east section of the State. Rising from them like islands are a number of isolated mountain groups, such as the Highwoods, Bear Paws, Little Rockies, Big Snowy mountains and well named Sweet Grass hills. The valleys of the principal streams are deeply eroded, and in their bottom lands contain a black clayey loam, making excellent farm lands which can be irrigated. Between the valley floor and the dry bench lands a fringe of steep bluffs with intersecting coulées is found. The bench lands usually have a thick layer of sandy loam resting on gravel, and it is here that the so-called "dry-land farming" of the State is done. With the exception of a small part of Glacier park and Teton county, which is drained by the Belly and St. Mary's rivers into Hudson bay, the State east of the divide is drained by the Missouri river and its tributaries into the Gulf of Mexico. The Missouri is formed by a union of the Jefferson, Madison and Gallatin rivers. Flowing north from Three Forks, it is joined from the west by the Sun and Teton rivers, and from the north-west by the Marias river. Turning then to the eastward and flowing across the State, it is joined from the south by the Judith and the Musselshell and from the north by the Milk rivers. Finally, just beyond the eastern boundary, it is joined by the Yellowstone, which with its tributaries, the Big Horn, Powder and Tongue rivers, drains the whole southeastern quarter of the State. The channel of the Missouri is generally erratic and its bed sandy and shifting. Its waters are muddy. The Yellowstone, in contrast, is a stream of bright, clear water running over a gravelly bed.

The average altitude of Montana is 3,400 ft., with more than one-half of the State lying under 3,000 feet. This low average, much lower than that of any other Rocky mountain State, to some extent offsets its northern position and tempers the climate.

Climate.—In the west the climate is generally delightful, it being there greatly affected by the warm, dry "Chinook" wind which blows from the Pacific ocean; to some extent the wind modifies the temperature nearly to the eastern border.

The mean annual temperature ranges from 37° in the north-east to 47° in the sheltered valleys among the mountains. The amount of precipitation is greater in the north-west and on the mountains which, standing in isolated groups upon the plains, are frequently in summer the focus of local thunder showers. The average annual precipitation ranges from 10 to 15 in. on the Great Plains to 20 in. or more in the north-west and in limited areas in the higher mountain region. Nearly one-half of the rain falls during the four months from May to August inclusive.

Fauna.—The buffalo, or bison, which formerly ranged the plains in large herds, were almost exterminated, but were represented by a herd of 459 animals (1923) on the national bison range of 20,000 ac. in western Montana. Moose and elk are found only occasionally in the wilder regions; mountain sheep, antelopes, black and grizzly bears, wolves, pumas and lynx are also becoming rare. Black-tailed and mule deer are still favourite game for sportsmen. Geese, ducks and grouse are numerous. Trout, salmon, grayling and whitefish inhabit many of the lakes, rivers and mountain streams, and a Government fish hatchery at Bozeman, Gallatin county, restocks depleted waters.

Flora.—The Great Plains are covered for the most part with bunch grass only, which grows in tufts, leaving the ground visible between, and except in May and June presents a yellow and withered appearance. Mixed with the bunch grass are buffalo grass and blue-joint and occasional patches of sagebrush. The bluffs along the principal river valleys, especially those in the south-east, are bare, but on the bottom lands along the rivers and streams considerable patches of cottonwood and willows are common. On the higher parts of the mountains are barren rocks where the growth of timber is scant; but many of the lower mountain slopes, especially those along the western border, are clothed with heavy timber, chiefly yellow pine, red fir and tamarack.

Government.—The State is governed under a constitution adopted in 1889. To amend this constitution an affirmative vote of two-thirds of the members of each house of the legislature is required, followed by an affirmative vote of a majority of the electors voting thereon at the next general election; or, as an alternative method, by a like vote of each house of the legislature and of the electorate, a convention may be called to revise or amend it, a revision or amendment in this manner requiring the ratification of the electorate not less than two months nor more than six months after the adjournment of the convention.

The officers of the executive department are the governor, lieutenant-governor, secretary of State, attorney-general, treasurer, auditor and superintendent of public instruction, each of whom is elected for a term of four years. The governor, with the advice and consent of the senate, appoints various administrative officers, the more important being the register of lands, the State forester, the State engineer, the dairy commissioner, the commissioner of labor and industry, and the mine inspectors. He may veto any bill passed by the assembly, or in the case of a bill making appropriations of money he may veto any item of it, and no bill or item of an appropriation which he vetoes within five days (Sunday excepted) after it has been presented to him can become a law or a part of a law unless passed over his veto in

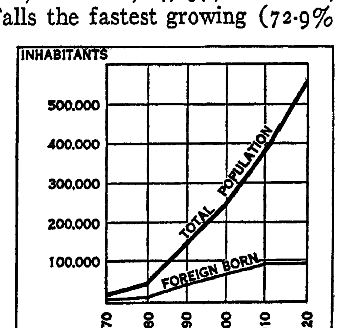
each house by a two-thirds vote of the members present.

The legislature consists of a senate and a house of representatives, meeting regularly on the first Monday of January in odd-numbered years only. Senators are elected, one from each county, for a term of four years; representatives are elected, one or more from each county according to population, for a term of two years. The senators in 1927 numbered 56, and the representatives 102. The action of the legislature is much restricted by the Constitution, a long list of cases being named in which that body is prohibited from passing any local or special laws. In 1906 an amendment to the State Constitution authorized a limited initiative and referendum. The administration of justice is entrusted to a supreme court, 18 district courts, and at least two justices' courts in each organized township, besides police and municipal courts. The supreme court is composed of a chief justice and four associate justices elected for a term of six years. It holds four sessions a year at Helena and has limited original and plenary appellate jurisdiction. For most district courts there is only one judge, but for the more populous districts there are two judges; they are all elected for four years. Montana has two representatives in the U.S. Congress, elected from two separate districts.

Population.—In 1920 Montana's population was 548,889; in 1910, 376,053; and in 1900, 243,329. Between 1900 and 1910 the increase was 54·5%; between 1910 and 1920, 46%. An average of estimates by four different methods made by the State bureau of vital statistics gives 520,148 for 1925, a decrease of nearly 30,000 since 1920. There were 42,626 fewer people on farms, and 10,781 fewer farms than in 1920. By 1930 conditions had improved but the population was 537,606, a loss of 11,283.

In 1910 there were 226,872 males and 149,181 females; in 1920, 299,941 males and 248,948 females. Of the total population 97·3% are white, 2% Indian and the rest negro and oriental. The Indian population in 1920 was 12,374, an increase of 2,298 over 1910. The Indians belonged to the Blackfeet, Crow, Salish (Flathead), Sioux, Assiniboine, Gros Ventres and Northern Cheyenne tribes. The reservations on which they formerly lived have been broken up and the land allotted to individual members of the tribes.

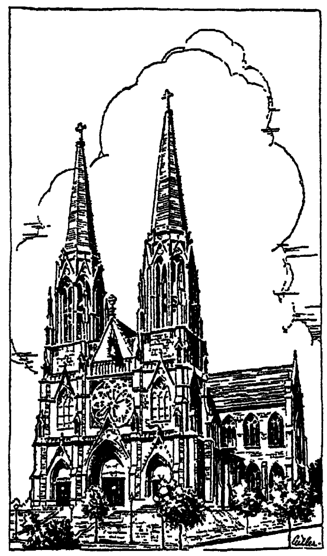
In 1920, 93,620 were foreign born, 101,918 born of foreign parents, and 62,919 of mixed foreign-born and native parentage. The largest groups of foreign born were 20,131 from Scandinavian countries, 19,577 from the United Kingdom, 7,875 from Germany and 5,203 from Russia. The urban population in 1920 was 172,011 or 31·3%; the rural 376,878 or 68·7%. There were six cities in 1930 with a population of 10,000 or more; Butte, 39,532; Great Falls, 28,822; Billings, 16,380; Missoula, 14,657; Anaconda, 12,494; Helena, 11,803. Great Falls the fastest growing (72·9% increase 1910–20), is also the youngest; it was founded in 1883.



GRAPH OF GROWTH OF POPULATION IN MONTANA, AND FOREIGN PERCENTAGE

Finance.—The State legislature biennially fixes the rate of taxes for State purposes. In 1920 the people by a referendum vote fixed the annual tax at 3½ mills for a ten-year period. Of this, 1½ mills is for the support of the four units of the State university, and the remaining 2 mills for the general State fund. In 1921 the legislature passed a small tax on oil and coal production, and in addition a tax of one cent a gallon on gasolene, which was raised to 2 cents a gallon in 1923 and to 3 cents in 1927. In 1923 an effective inheritance tax was passed. One of the chief issues of Montana's politics has been the taxation of mines and their output. The mines, in proportion to their resources, paid a not excessive share of the taxes, and the agricultural and live stock interests contributed heavily. In 1924 the people were able to pass an initiative measure providing for a graduated tax of from 0·25% to 1% of the gross product of metal mines. Half of this tax and of the inheritance tax goes to the school fund, and half to the general fund. The gasolene tax goes to the State highway commission.

The State had a bonded indebtedness in 1926 of $5,559,000, $675,000 of which were capital building bonds, and the remainder educational bonds. The assessed valuation of all the taxable property in the State in 1926 was $1,376,623,060, and the taxable valuation $435,510,159. On this valuation $1,946,032 was levied for State purposes, $9,502,456 for county purposes, $10,555,556 for school purposes and $3,413,404 for city and town purposes, making a grand total of $26,380,466.



BY COURTESY OF THE CHAMBER OF COMMERCE, HELENA
ST. HELENA CATHEDRAL, HELENA

In 1925 there were 235 banks in the State, 85 of them national banks. Their total resources or liabilities were $160,583,000; loans and discounts, $78,337,000; investments, $39,364,000; capital, surplus and undivided surplus, $18,787,000. Savings deposits were $75,541,000 in 1920, $49,111,000 in 1924 and $55,579,000 in 1925.

Education.—In 1925–1926 there were 2,883 elementary schools with an enrolment of 95,494 pupils and 192 high schools (19 of them county high schools) with an enrolment of 20,941. School revenue from all sources totalled $12,543,512, 50·79% of it coming from district taxes, 21·6% from a general 6 mill county tax, 13·6% from a county high school tax, and 13·85% from school lands and special State taxes. School expenditures for the year were $12,419,374—$7,178,599 of which was for instruction, $2,497,819 for plant operation and maintenance, and the rest for miscellaneous purposes. Of the public school income $1,091,472 came from the public school lands.

There are four State institutions of higher learning, the University of Montana at Missoula, the College of Agriculture and Mechanic Arts at Bozeman, the School of Mines at Butte, and the State Normal school at Dillon. All are under one administrative head called the chancellor. Intermountain and St. Charles colleges are in Helena.

Agriculture and Live Stock.—The types of farming best suited to the varying climate and soils of the State are yet to be determined. For a long time it was believed that only in the mountain valleys could crops be grown without irrigation, and before 1890 the farming was done there. Between then and 1905 expansion was chiefly on irrigated land, and since 1905 it has been on dry lands. In 1923, 90% of the wheat, 80% of the oats, ⅘ of the barley and most of the maize were grown on dry lands. On irrigated land the acreage and the value of tame and wild hay exceeded those of all other crops. Sugar beets were grown only on irrigated land. The first irrigation consisted of crude private ditches direct from the mountain streams to the land, and land situated in a position to be thus watered was the first to be settled. A number of the modern developments are Federal undertakings, notably the Huntley project in Yellowstone county, the Lower Milk river project, the Sun river project, and the Lower Yellowstone project. In 1920, 10,807 farms had 1,681,729 ac. actually under irrigation or 10·5% of the irrigated land of the United States. Capital invested in irrigation totalled $52,143,363 or $18.94 an acre. The average cost per acre for operation and maintenance in 1919 was $1.26, while the average gross value per acre of all crops grown on irrigated land was $35.03, as against $18.30 per acre for all land cropped in the State.

The acreage of farm land jumped from 13,546,000 in 1910 to 35,071,000 in 1920, and in 1925 back to 32,740,000. The number of farms decreased from 57,677 in 1920 to 46,906 in 1925. In the same period the average size per farm increased from 608·1 ac. to 698 ac., showing that live stock ranches were again absorb-

ing the homesteads. In 1920 the value of farm land was $691,912,000, in 1925 $387,090,000. The farms mortgaged were 20·6% in 1910, and 59·5% in 1920. The figures reveal the crisis which agriculture has passed through in recent years. In 1925, wheat to the value of $48,243,000 was raised ($16,000,000 less than in 1924), with a crop value per acre of $14.98; oats to the value of $7,608,000 ($11.92 per acre); corn $6,255,000 ($15.68 per acre); potatoes $6,048,000 ($172 per acre); and barley $2,359,000 ($15.12 per acre). The total value of all crops was $161,700,000 in 1927, compared with $136,984,000 in 1924 and $89,872,000 for the 1919–23 average. Indian corn has made the most rapid proportional increase. Most of it is used for silage and roughage, but certain varieties have been acclimated so that they mature. Rye, barley and oats are also increasing in acreage and are consumed mainly on the farm as feed. The quality of wheat is superior to that of any other State. In 1922 84% of the crop was officially estimated as grade No. 1, and for the three-year period 1920–22, 74·4% fell into the same class.

In 1919, cattle shipments reached a new peak of 641,337 head. Part of that year's immense shipment was the result of a severe drought. That and a still more severe winter following and the general deflation of prices constituted a series of blows from which stockmen have been slow to recover. Dairying has made steady progress. In 1920 sheep suffered from the same reverses as cattle, but recovered sooner because of a sharp increase in wool and lamb prices in 1922. In 1925, the wool clip was 20,871,000 lb. and the average weight of fleece 8·7 lb., compared with an average of 7·6 lb. for the country as a whole. Horses, the source of a large share of the State's live stock income between the years 1898 and 1918, are no longer in active demand. Swine have proved very profitable. Montana farms are also raising more poultry than ever before, especially turkeys.

Mining.—Next in importance to agriculture is the mining industry. In 1919 it employed 16,129 men and paid $25,724,000 in wages. For the same year the value of the State's mineral output was $49,924,000, while in 1925 it was $79,261,284. Copper is now the leading mineral, representing about 60% of the value of the State's metal production. The output in 1925 was 268,910,847 lb., valued at $38,185,340; in 1926, 257,271,936 lb., valued at about $36,000,000. The whole output is from a limited district of several square miles in Butte. Since operations began in the early '80s, this area has produced 27% of the copper production of the nation. The Anaconda Copper Co., the largest organization in 1928 for mining, smelting, refining and fabricating copper, with a capital stock of $150,000,000, has its principal mines here. At Anaconda is located one of the largest non-ferrous smelters in the world, which treated 2,882,903 tons of copper ore and 478,993 tons of zinc ore in 1926. The political life of Montana has been strongly influenced by the copper industry. Montana ranks in second place among the States in production of silver, the amount in 1925 having been 13,158,191 troy oz., valued at $9,131,784. Most of it is recovered as a by-product in refining the copper and zinc ores of the Butte district. In 1916 an electrolytic process was devised whereby zinc ores, before considered only a detriment in the refining of copper, could be reduced on a paying basis. Zinc now rivals silver for second place in importance and bids fair soon to exceed it. The production in 1925 amounted to 115,316,000 lb., valued at $8,764,086. The Anaconda Copper Co. in 1926 enlarged the capacity of its zinc plant at Great Falls 33⅓%. Gold is an important mineral, though also recovered incidentally in the process of smelting and refining copper and zinc. The 1925 production of 84,022 oz. was valued at $1,736,900. The greatest, best developed and most available domestic reserves of high-grade manganese ore in the Union are also in Montana. During the World War, production of this was heavy, but low-priced ore from foreign lands has since reduced the amount to about 50,000 tons annually. Montana also produces about one-half the national output of white arsenic used in fighting the boll weevil pest on cotton plants. In 1925 the State ranked sixth in the production of lead, with an output of 37,530,000 pounds. Coal is found in almost every part of the State, the reserves of the State being estimated by the U.S. geological survey to contain 409,000,000,000 tons or 11·5% of the total coal reserves of the nation. The coal includes 381,000,000,000 tons of lignite. Annual production of coal averages about 3,000,000 tons. Much is used in the State by the railway, mining and manufacturing industries. The manufacture of the lignite into briquettes has opened a way to the utilization of these valuable deposits commercially. On Yogo creek in the Judith basin is a sapphire mine that produces one-half of the national output in precious stones. The quality of the blue sapphires is unexcelled by those of any other district in the world. Since the mine was opened in 1898, it has produced gems worth about $12,000,000. Oil was discovered in commercial quantities in 1919. The production for 1926 was 7,645,000 bbl., valued at $11,800,000.

Lumbering.—The timber stand in Montana was estimated in 1925 at 54,000,000,000 board ft. (9,598,000,000 yellow pine, 21,987,000,000 Douglas fir and larch, 941,000,000 white pine, 21,474,000,000 others, including lodgepole). Of this stand, national forests contain 38,000,000,000 board ft.; State forests 2,000,000,000 board ft.; and private forests, 14,000,000,000 board feet. The rate of cutting in 1923–27 was about 400,000,000 board ft. annually. Destruction by fire has averaged 187,644,000 board ft. or 102,878 ac. annually. In contrast the annual growth estimate is 859,000,000 board feet. In 1922 there were 141 active sawmills in the State cutting approximately 400,000,000 board ft., the lumber representing a value of approximately $10,000,000.

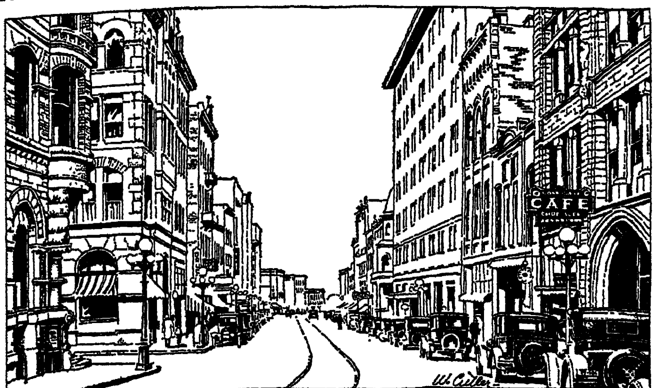
Manufactures.—The vast supplies of water-power in Montana give hopes of great industrial development. The hydro-electric plants in 1923 had a capacity of 400,000 h.p., an increase of 120,000 in three years. Much of this was used for the operation of electric trains. The potential hydro-electric development is estimated at 4,000,000 horse-power. In 1920 Congress passed a bill authorizing the secretary of the interior to lease the undeveloped power sites, and the completion of the developments will add greatly to the electric power available. In 1909 the total value of manufactures was $73,000,000; in 1925 it had increased to $205,474,257. In 1920 there were 195 lumber mills, 75 flour mills, 31 creameries, seven cheese factories and two canning factories.

Transportation.—Montana is served by three transcontinental railways: the Great Northern traversing the north; the Northern Pacific traversing the south; and the Chicago, Milwaukee and St. Paul paralleling the Northern Pacific through the mountains, but running north of it for the most part across the plains. At Butte the Oregon Short Line from Utah connects with all three, and at Billings the Burlington from Wyoming and the southeast with the Northern Pacific and the Great Northern. Three transcontinental highways cross the State, the Roosevelt highway in the north and the Yellowstone and National Park highways in the south. There were 7,957 m. of State highway in 1924, of which 7,237 were unsurfaced. Expenditures by the State highway department in 1924 (including Federal aid) were $1,788,000.

History.—That part of Montana lying east of the continental divide became a part of the United States with the purchase of Louisiana from France in 1803. The smaller region west of the divide belonged to the Oregon country, which was held jointly by the United States and Great Britain until the treaty in 1846 gave the United States sole title south of the 49th degree of latitude.

Montana may have been seen by white men as early as 1742, depending on whether the "high," "well-wooded" mountains reached by the expedition under Pierre and Chevalier de la Verendrye, French traders from Canada, were the Big Horn range, the Laramie range or the Black Hills. The next exploration was by the Lewis and Clark Expedition, which reached the eastern borders of the State in April 1805. They ascended the Missouri to the confluence of the three streams that form it, which they named the Jefferson, Madison and Gallatin rivers. Ascending the Jefferson, they crossed the divide to the Bitter Root valley, which they descended until Lo Lo Pass gave them an opportunity to go beyond the Bitter Root range into Idaho. On their return they re-entered Montana by the same pass and then divided their party. Lewis led one division up the Big Blackfoot river and crossed by Lewis and Clark pass to the Missouri near Great Falls. Clark,

with the other division, ascended the Bitter Root and, crossing the headwaters of the Missouri, reached the Yellowstone, which he was the first to explore. The parties met again at the confluence of the Yellowstone and Missouri. The reports of this expedition stimulated the Missouri fur traders to extend their operations into the region. Manuel Lisa in 1807 built a trading post on the Yellowstone at the mouth of the Big Horn river, the first building



BY COURTESY OF THE CHAMBER OF COMMERCE, HELENA

MAIN STREET, FORMERLY "LAST CHANCE GULCH," IN HELENA, MONTANA

in Montana. The same year one of his men, John Colter, losing the trail in the upper Yellowstone country, discovered the future Yellowstone Park. After 1807 Lisa's traders made annual trips into the region. West of the divide David Thompson, of the North-West Company, explored the Kootenai river in 1808; the same autumn he sent Finan McDonald to build a trading house at Kootenai Falls, the first building on the western slopes of the State. Thompson himself built Salish House, a more permanent post, on Clark's Fork the following year. For the next half century the fur trade dominated the region. That on the eastern slope was soon monopolized by the American Fur Company. Kenneth McKenzie was put in charge of the "Upper Missouri Outfit" of this company in 1827, and from Ft. Union, which he built in 1829 near the confluence of the Missouri and Yellowstone rivers, he ruled the traders and Indians of the vast territory. The trade west of the divide was controlled by British interests.

Iroquois Indians, employed by the fur companies to teach the mountain Indians to hunt for furs, taught them also the Catholic religion. The Salish Indians sent four separate delegations to St. Louis to bring back the "Black Robes," and Father P. J. De Smet returned with the last of these in 1840. In 1841 he founded St. Mary's Mission in the Bitter Root valley.

A number of settlers trickled into the Bitter Root valley between 1850 and 1860, but the real rush of immigration came only when gold was discovered. The first strike was made in 1858 on Gold creek by James and Granville Stuart, and in 1861 and 1862 a little colony of pioneers was panning the sands of the stream. The latter year saw a richer strike made on Grasshopper creek, in the Beaverhead country, where Bannack sprang up, the liveliest town in the region in 1863. Also in 1863 gold was discovered in Alder Gulch, one of the richest placer areas the world has known, where Virginia City grew up and soon outdistanced all its rivals. At Virginia City in 1864 the first newspaper, *The Montana Post,* appeared. The same year Last Chance Gulch, the site of the future capital city of Helena, was discovered. And finally, in that year Montana was organized as a separate Territory, Sidney Edgerton was appointed its first governor, and the first legislature met at Bannack.

New placer discoveries were constantly made during the next few decades of Montana's history until there were camps in hundreds of gulches. By 1876 gold to the value of $144,400,000 was produced. Metalliferous quartz was discovered at Helena, Philipsburg and Butte, at the last two places containing silver veins. The Philipsburg district was especially prosperous until the decline of silver values forced many of the mines to close. Not until the early '80s was the copper discovery made at Butte which was to result in the place becoming one of the world's greatest mining camps. The large influx of miners brought difficulties with the Indians. It had been to the interest of the fur traders and the missionaries to keep peace with and among the various tribes, but no such mutual benefit relations existed between the Indians and the gold hunters. The Sioux and Cheyennes united in trying to prevent immigrants from passing over the Bozeman trail, and this important short cut to Montana from the Platte had to be closed by the Government. The Sioux were again on the war-path in 1876, because the miners had invaded their Black Hills reserve, and that year they annihilated Gen. Custer's five companies of cavalry on the Little Big Horn river. So many of the Indians were killed, however, that their power was broken. The Government began to make treaties with the different tribes, in which the boundaries of the Indian country were carefully defined; the Indians were ordered to stay on these reservations. The last disturbance came in 1877 when Chief Joseph of the Nez Percés refused to stay on the reservation and attempted to escape with his followers into Canada. After giving desperate battle in the Big Hole country and conducting a masterly retreat over more than 1,000 m., he was surrounded in the Bear Paw mountains, and was forced to surrender to Gen. Miles.

During all these years the eastern three-fifths of the State was unsettled, and settlement came only when agriculture and the live stock industry began to expand eastward. The first stock and the first crops were raised near the mines and sold to the mining camps. Prices were high, and disappointed miners found the production of food a lucrative business. The first drive of cattle from Texas to Montana was made in 1869. The first rail shipments were trailed from western Montana to the Union Pacific at Ogden, Utah. After the Indians were quieted in 1877, most of the shipments were driven to Cheyenne, Wyo. The completion of the Northern Pacific railway through the State (1879–83) immensely stimulated the cattle industry. In 1885, 79,089 head were shipped to market; in 1891, 250,000 head; and from then to 1912, the shipments amounted to more than 200,000 head annually. Sheep raising was developed in Montana even before the cattle industry, because it was not so dependent upon transportation. Large quantities of wool were shipped by flatboat down the Missouri and Mississippi rivers to New Orleans and thence by steamer to Boston. Sheep increased from 4,212 in 1870 to 249,978 by 1880, to 1,990,000 in 1890, and to 6,170,000 in 1900, when the wool clip of Montana exceeded that of any other State. In the first decade of the present century the encroachment of the homesteaders began to be felt by the stockmen, many of whom sold out as agricultural development increased land values.

Before 1890 the comparatively little farming was subsidiary to the live stock industry. Farming was developed first in the Bitter Root and Gallatin valleys. By 1880 it showed a tendency to creep eastward into the Judith basin and down the Yellowstone. Oats were the chief crop, the stage lines and military posts affording a home market for it. The construction of the Northern Pacific extended the area of rural settlement eastward along the Yellowstone as far as Glendive. Wheat could now be raised for shipment. Farms increased from 1,519 in 1880 to 5,603 in 1890 and to 13,370 in 1900, when there were 1,736,701 ac. of improved land. Over one-half of this acreage was irrigated, while in 1920 only 15% of the 11,007,278 ac. of improved land were irrigated. This shows the tremendous influx of dry-land homesteaders in the two decades. In 1900 little farming was done in eastern Montana except in the Yellowstone and Milk river valleys; but by 1910 the bench lands back of the river valleys were being settled, and between 1910 and 1920 every eastern county in the State, except Cascade, showed an increase in rural population of 50% or over. By 1920, 37.5% of the State's total area was devoted to farms.

From the beginning of Statehood (1889) up to 1928 Montana has had only two Republican governors, Richards (1893–97) and Dixon (1921–25). In presidential elections the State has fluctuated between the Democrats and Republicans (five times Republican and four times Democrat).

Bibliography.—The important State publications are the *Biennial Reports* of the superintendent of public instruction, the register of State lands, the State forester, the State board of health, and the State board of equalization; the *Annual Reports* of the State treasurer and the agricultural experiment station; the publications of the depart-

ments of agriculture, labour and industry; the *Bulletins* of the agricultural experiment station; the *Montana Farm News;* the University of Montana *Bulletins* (including the bureau of mines and metallurgy series); and the *Contributions to the Historical Society of Montana* (1873–1923). H. F. Sanders, *History of Montana* (1913); K. H. Fogarty, *The Story of Montana* (1916); and Tom Stout, *Montana, Its Story and Biography* (1921) are the best general histories. *See* also T. J. Dimsdale, *The Vigilantes of Montana* (1866); H. M. Chittenden, *History of the American Fur Trade of the Far West* (1902); A. L. Stone, *Following Old Trails* (1913); and G. Stuart, *Forty Years on the Frontier* (1925). (T. J. W.)

MONTANELLI, GIUSEPPE (1813–1862), Italian statesman and author, was born at Fucecchio in Tuscany, and in 1840 was appointed law professor at Pisa. In 1847 he founded a newspaper called *L'Italia,* the programme of which was "Reform and Nationality." In 1848 he formed a ministry at Leopold's invitation, and on Jan. 10, 1849, induced the grand duke to establish a national constituent assembly. But Leopold, alarmed, fled from Florence, and Montanelli, Guerrazzi and Mazzini were elected "triumvirs" of Tuscany. Like Mazzini, Montanelli advocated the union of Tuscany with Rome. But after the restoration of the grand duke, Montanelli, who was in Paris, was tried and condemned by default; he remained some years in France, where he became a partisan of Napoleon III. On the formation of the kingdom of Italy he returned to Tuscany and was elected member of parliament; he died in 1862.

His most important literary work is his *Memorie sull' Italia e specialmente sulla Toscana dal 1814 al 1850,* in 2 vols. (Turin, 1853).

See Assunta Marradi, *G. Toscanelli e la Toscana dal 1815 al 1862* (1909).

MONTAÑES, JUAN MARTINEZ (*c.* 1580–1649), Spanish sculptor, was born at Alcala-la-real, in the province of Granada. His master was Pablo de Roxas, his first known work (1607) being a boy Christ, now in the sacristy of the *capella antigua* in the cathedral of Seville. The great altar at Santiponce near Seville was completed in 1812. Montañes executed most of his sculpture in wood, covered with a surface of polished gold, and coloured. Other works were the great altars at Santa Clara in Seville and at San Miguel in Jerez, the Conception and the realistic figure of Christ crucified, in the Seville cathedral; the figure of St. John the Baptist, and the St. Bruno (1620); a tomb for Don Perez de Guzman and his wife (1619); the St. Ignatius and the St. Francis of Borja in the university church of Seville. Montañes died in 1649. His works are more realistic than imaginative, but this, allied with an impeccable taste, produced remarkable results. The equestrian statue of King Philip IV., cast in bronze by Pietro Tacca in Florence and now in Madrid, was modelled by Montañes. He had many imitators, his son Alonzo Martiñez, who died in 1668, being among them.

MONTANISM, a somewhat misleading name for the movement in the 2nd century which, along with Gnosticism, occupied the most critical period in the history of the Early Church. It was the overthrow of Gnosticism and Montanism that made the "Catholic" Church. In this article an account will be given of the general significance of Montanism in relation to the history of the Church in the 2nd century, followed by a sketch of its origin, development and decline.

1. From the middle of the 2nd century a change began to take place in the outward circumstances of Christianity. The Christian faith had hitherto been maintained in a few small congregations scattered over the Roman empire. These congregations were provided with only the most indispensable constitutional forms. This state of things passed away. The Churches soon found numbers within their pale who stood in need of supervision, instruction and regular control. The enthusiasm for a life of holiness and separation from the world no longer swayed all minds. In many cases sober convictions or submissive assent took the place of spontaneous enthusiasm. Then, in addition to this, Christians were already found in all ranks and occupations—in the Imperial palace, among the officials, in the abodes of labour and the halls of learning, amongst slaves and freemen. Should the Church take the decisive step into the world, conform to its customs, and acknowledge as far as possible its authorities? Or ought she, on the other hand, to remain a society of religious devotees, separated and shut out from the world? That this was the question at issue is obvious enough now, although it could not be clearly perceived at the time. It was natural that warning voices should then be raised in the Church against secular tendencies and that the well-known counsels about the imitation of Christ should be held up in their literal strictness before worldly Christians. The Church as a whole, however, under pressure of circumstances rather than by a spontaneous impulse, decided otherwise. She marched through the open door into the Roman state, and settled down there to Christianize the state by imparting to it the word of the Gospel, but at the same time leaving it everything except its gods. On the other hand, she furnished herself with everything of value that could be taken over from the world without overstraining the elastic structure of the organization which she now adopted. With the aid of its philosophy she created her new Christian theology; its polity furnished her with the most exact constitutional forms; its jurisprudence, its trade and commerce, its art and industry, were all taken into her service; and she contrived to borrow some hints even from its religious worship. With this equipment she undertook, and carried through, a world-mission on a grand scale. But believers of the old school protested in the name of the Gospel against this secular Church. They joined an enthusiastic movement which had originated in a remote province, and had at first merely local importance. There, in Phrygia, under the leadership of a prophet known as Montanus, the cry for a strict Christian life was reinforced by the belief in a new and final outpouring of the Spirit—a coincidence which has been observed elsewhere in Church history—as, for instance, among the early Quakers and in the Irvingite movement. These zealots surrendered themselves to this guidance. In so doing, however, they had to withdraw from the Church, to be known as "Montanists," or "Kataphrygians," and thus to assume the character of a "heresy." Their enthusiasm and their prophesyings were denounced as demoniacal; their expectation of a glorious earthly kingdom of Christ was stigmatized as Jewish, their passion for martyrdom as vainglorious and their whole conduct as hypocritical. Nor did they escape the more serious imputation of heresy on important articles of faith; indeed, there was a disposition to put them on the same level with the Gnostics. The effect on themselves was what usually follows in such circumstances. After their separation from the Church, they became narrower and pettier in their conception of Christianity. Their asceticism degenerated into legalism, their claim to a monopoly of pure Christianity made them arrogant.

2. Such is, in brief, the position occupied by Montanism in the history of the ancient Church. The rise and progress of the movement were as follows.

At the close of the reign of Antoninus Pius—probably in the year 156 (Epiphanius)—Montanus appeared at Ardabau in Mysia, near the Phrygian border, bringing revelations of the "Spirit" to Christendom. The burden of the new prophecy seems to have been a new standard of moral obligations, especially with regard to marriage, fasting and martyrdom. But Montanus had larger schemes in view. He wished to organize a special community of true Christians to wait for the coming of the Lord. The small Phrygian towns of Pepuza and Tymion were selected as the headquarters of his church. Funds were raised for the new organization, and from these the leader and missionaries, who were to have nothing to do with worldly life, drew their pay. Two women, Prisca and Maximilla, were moved by the Spirit; like Montanus, they uttered in a state of frenzy the commands of the Spirit, which urged men to a strict and holy life.

For twenty years this agitation appears to have been confined to Phrygia and the neighbouring provinces. But after the year 177 a persecution of Christians broke out simultaneously in many provinces of the Empire. Like every other persecution it was regarded as the beginning of the end. It would seem that before

this time Montanus had disappeared from the scene; but Maximilla, and probably also Prisca, were working with redoubled energy. And now, throughout the provinces of Asia Minor, in Rome, and even in Gaul, amidst the raging of persecution, attention was attracted to this remarkable movement. The desire for a sharper exercise of discipline, and a more decided renunciation of the world, combined with a craving for some plain indication of the Divine will in these last critical times, had prepared many minds for an eager acceptance of the tidings from Phrygia. And thus, within the large congregations where there was so much that was open to censure in doctrine and constitution and morals, conventicles were formed in order that Christians might prepare themselves by strict discipline for the day of the Lord. As a rule, the bishops were resolute enemies of the Montanistic enthusiasm. It disturbed the peace and order of the congregations, and threatened their safety. Moreover, it made demands on individual Christians such as very few could comply with.

Early in the last decade of the 2nd century two considerable works appeared in Asia Minor against the Kataphrygians. The first, by a bishop or presbyter whose name is not known, was written apparently about the year 193. The other was written by a certain Apollonius forty years after the appearance of Montanus, consequently about 196. From these treatises we learn that the adherents of the new prophecy were very numerous in Phrygia, Asia and Galatia (Ancyra), that they had tried to defend themselves in writing from the charges brought against them, that they possessed a fully developed independent organization, that they boasted of many martyrs, and that they were still formidable to the Church in Asia Minor. Many of the small congregations had gone completely over to Montanism, although in large towns, like Ephesus, the opposite party maintained the ascendancy. Every bond of intercourse was broken, and in the Catholic Churches the worst calumnies were retailed about the deceased prophets and the leaders of the societies they had founded. In many Churches outside of Asia Minor a different state of matters prevailed. Those who accepted the message of the new prophecy did not at once leave the Catholic Church in a body. They simply formed small conventicles within the Church. Such, for example, appears to have been the case in Carthage (if we may judge from the Acts of the martyrs Perpetua and Felicitas) at the commencement of the persecution of Septimius Severus about the year 202. But even here it was impossible that an open rupture should be indefinitely postponed. The bishops and their flocks gave offence to the Montanists on so many points that at last it could be endured no longer. The latter wished for more fasting, the prohibition of second marriages, a frank, courageous profession of Christianity in daily life, and entire separation from the world; the bishops, on the other hand, sought to make it as easy as possible to be a Christian, lest they should lose the greater part of their congregations. And lastly, the bishops were compelled more and more to take the control of discipline into their own hands, while the Montanists insisted that God Himself was the sole judge in the congregation. On this point especially a conflict was inevitable; and it was at this juncture that Tertullian, the most famous theologian of the West, left the Church whose cause he had so manfully upheld against pagans and heretics. He too had come to the conviction that the Church had forsaken the old paths and entered on a way that must lead to destruction.

The writings of Tertullian afford the clearest demonstration that what is called Montanism was, at any rate in Africa, a reaction against secularism in the Church. There are no other indications that Montanism in Carthage was a very different thing from the Montanism of Montanus. Western Montanism, at the beginning of the 3rd century, admitted the legitimacy of almost every point of the Catholic system. It allowed that the bishops were the successors of the apostles, that the Catholic rule of faith was a complete and authoritative exposition of Christianity, and that the New Testament was the supreme rule of the Christian life. Montanus himself and his first disciples had been in quite a different position. In his time there was no fixed, divinely instituted congregational organization, no canon of New Testament Scriptures, no anti-Gnostic theology, and no Catholic Church. There were simply certain communities of believers bound together by a common hope, and by a free organization, which might be modified to any required extent. When Montanus proposed to summon all true Christians to Pepuza, in order to live a holy life and prepare for the day of the Lord, there was nothing whatever to prevent the execution of his plan except the inertia and lukewarmness of Christendom. But this was not the case in the West at the beginning of the 3rd century. At Rome and Carthage, and in all other places where sincere Montanists were found, they were confronted by the imposing edifice of the Catholic Church, and they had neither the courage nor the inclination to undermine her sacred foundations. This explains how the later Montanism never attained a position of influence. In accepting, with slight reservations, the results of the development which the Church had undergone during the fifty years from 160 to 210 it reduced itself to the level of a sect. Tertullian exhausted the resources of dialectic in the endeavour to define and vindicate the relation of the "spiritual" to what he called the "psychic" Christians; but no one will say he has succeeded in clearing the Montanistic position of its fundamental inconsistency.

Bibliography.—Ritschl's investigations in his *Entstehung der altkatholischen Kirche,* 2nd ed. 1857, superseded previous work. The later works, of which the best and most exhaustive is that of N. Bonwetsch, *Die Geschichte des Montanismus* (1881), all follow the lines laid down by Ritschl. *See* also Gottwald, *De montanismo Tertulliani* (1862); Réville, "Tertullien et le montanisme" in the *Revue des deux mondes* (Nov. 1, 1864); Stroelin, *Essai sur le montanisme* (1870); De Soyres, *Montanism and the Primitive Church* (London, 1878); W. Cunningham, *The Churches of Asia* (London, 1880); Renan, "Les Crises du Catholicisme Naissant" in *Rev. d. deux mondes* (Feb. 15, 1881); H. Weinel, *Die Wirkungen des Geistes und der Geister im nachapostol. Zeitalter* (Freiburg, 1899); G. G. Selwyn, *The Christian Prophets* (London, 1900); and articles in Hastings' *Encyclopaedia of Religion and Ethics* and Herzog-Hauck, *Realencyklopädie.* Special points of importance in the history of Montanism have been investigated by Lipsius, Overbeck, Weizsäcker (*Theol. Lit.-Zeitung,* Nov. 4, 1882); Harnack, *Das Mönchthum, seine Ideale und seine Geschichte,* 2nd ed., 1882; Eng. trans., 1901; and *Z. f. Kirchengesch.* iii. 369–408, and H. J. Lawlor (*Journal of Theological Studies,* July 1908). Weizsäcker's short essays are extremely valuable, and have elucidated several important points previously overlooked. (A. Ha.; X.)

MONTARGIS, a town of central France, capital of an arrondissement in the department of Loiret, 47 m. E.N.E. of Orléans by rail. Pop. (1926), 12,129. Montargis was formerly the capital of the Gâtinais. Having passed in 1188 from the Courtenay family to Philip Augustus, it formed part of the royal domain. In 1528 Francis I. gave it as dowry to Renée d'Este, daughter of Louis XII., the famous Huguenot princess; from her it passed to her daughter Anne, and through her to the dukes of Guise; it was repurchased for the Crown in 1612. From 1626 till the Revolution the territory was the property of the house of Orléans. Montargis is particularly noted for its successful defence against the English in 1427. Both Charles VII. and Charles VIII. held court in the town.

The town is traversed by the Vernisson, by numerous arms of the Loing, and by the Briare canal, which unites with the canal of Orléans a little below it. It has a church (Ste. Madeleine), dating in part from the 12th century and including a Renaissance choir, and still preserves portions of its castle (12th to 15th centuries), which, previous to the erection of Fontainebleau, was a favourite residence of the royal family. Montargis is the seat of a sub-prefecture, and has tribunals of first instance and of commerce. It manufactures rubber, tar, asphalt, chemical manures, carriages, furniture, hosiery, boots and shoes. The town is an agricultural market, and its port has trade in coal, timber, sheep and farm produce, and skins.

MONTAUBAN, a town of south-western France, capital of Tarn-et-Garonne, 31 m. N. of Toulouse by the Southern railway. Pop. (1926) 18,346. The town stands on the right bank of the Tarn at its confluence with the Tescou. With the exception of Mont-de-Marsan, Montauban is the oldest of the *bastides* of southern France. Its foundation dates from 1144 when Alphonse Jourdain, count of Toulouse, granted it a liberal charter. The inhabitants were drawn chiefly from Montauriol, a village which

had grown up around the neighbouring monastery of St. Théodard. In the 13th century the town suffered much from the ravages of the Albigensians and from the Inquisition, but by 1317 it had recovered sufficiently to be chosen by John XXII. as the head of a diocese of which the basilica of St. Théodard became the cathedral. By the Treaty of Brétigny (1360) it was ceded to the English; but in 1414 they were expelled by the inhabitants. In 1560 the bishops and magistrates embraced Protestantism, expelled the monks, and demolished the cathedral. About ten years later it became one of the Huguenot strongholds, and formed a small independent republic. It was the headquarters of the Huguenot rebellion of 1621, and was vainly besieged by Louis XIII. for 86 days; nor did it submit until after the fall of La Rochelle in 1629, when its fortifications were destroyed by Richelieu. In the same year the plague cut off over 6,000 of its inhabitants. The Protestants again suffered persecution after the repeal of the Edict of Nantes.

A remarkable early 14th century bridge of brick connects the town with the suburb of Villebourbon. The *hôtel de ville,* 17th century with some older portions, on the site of a castle of the counts of Toulouse and once the residence of the bishops of Montauban, stands at the east end of the bridge. It contains a valuable library, and a museum including most of the work of Jean Ingres, the celebrated painter, who was born at Montauban. The Place Nationale is a square of the 17th century, entered at each corner by gateways giving access to a large open space surrounded by houses carried on double rows of arcades. The cathedral possesses the "Vow of Louis XIII.," one of the masterpieces of Ingres, and the church of St. Jacques (14th and 15th centuries) has a handsome octagonal tower. Montauban is the seat of a bishop, a prefect and a court of assize. It has tribunals of first instance and of commerce, a chamber of commerce and a board of trade arbitrators, and schools of commerce and viticulture. The commercial importance of Montauban is due rather to its trade in agricultural produce, horses, game and poultry, than to its industries, which include nursery-gardening, cloth-weaving, cloth-dressing, flour-milling, wood-sawing, and the manufacture of furniture, "swanskins," silk-gauze and straw hats. The town is a junction of the railways of the Southern and Orléans companies, and communicates with the Garonne by the Canal of Montech.

MONTAUSIER, CHARLES DE SAINTE-MAURE, Duc de (1610–1690), French soldier, was born on Oct. 6, 1610, being the second son of Léon de Sainte-Maure, baron de Montausier. His parents were Huguenots, and he was educated at the Protestant College of Sedan under Pierre du Moulin. He served brilliantly at the siege of Casale in 1630. Having served under Bernard of Saxe-Weimar in Germany in 1634 he returned to the French service in 1636, and fought in the Rhenish campaigns of the following years. He was taken prisoner at Rantzau in November 1643, and only ransomed after ten months' captivity. On his return to France he became a lieutenant-general. Montausier is famous for his courtship of Julie Lucine d'Angennes, daughter of Madame de Rambouillet, famous in the annals of French literature because of the *Guirlande de Julie,* a garland of verse consisting of madrigals by Montausier, Jean Chapelain, Guillaume Colletet, Claude de Malleville, Georges de Scudéry, Pierre Corneille (if M. Uzanne is correct in the attribution of the poems signed M.C.), Philippe Hubert, Simon Arnauld de Pomponne,[1] Jean Desmarests de Saint Sorlin, Antoine Gombaud (*le nain de la Princesse Julie*) and others. It was copied by the famous calligraphist N. Jarry in a magnificent ms., on each page of which was painted a flower, and was presented to Julie on her fête day in 1641.

Montausier had bought the governorship of Saintonge and Angoumois, and became a Roman Catholic before his marriage. The Parisian public regarded him as the original of Alceste in the *Misanthrope*. Montausier received from Louis XIV. the order of the Saint Esprit, the government of Normandy, a dukedom, and in 1668 the office of governor of the dauphin, Louis. He initiated the series of classics *Ad usum Delphini,* directed by the learned Huet, for the use of his pupil. He died on Nov. 17, 1690.

See Père Nicolas Petit, *Vie du duc de Montausier* (1729); Puget de Saint Pierre, *Histoire du duc de Montausier* (1784); Amédée Roux, *Un Misanthrope à la cour de Louis XIV. Montausier* (1860); O. Uzanne, *La Guirlande de Julie* (1875); E. Fléchier, *Oraisons funèbres du duc et de la duchesse de Montausier* (Paris, 1691); and contemporary memoirs.

[1](1618–1699), a son of Arnauld d'Andelly and minister of foreign affairs in succession to Lionne.

MONTBÉLIARD, a town of eastern France, capital of an arrondissement in the department of Doubs, 49 m. N.E. of Besançon on the P.L.M. line between that town and Belfort. Pop. (1926), 9,895. Montbéliard stands at the confluence of the Luzine and the Allaine. Forts on outlying hills connect it with Belfort on the one side and (through Blamont and the Lomont fortifications) with Besançon on the other. The castle of the counts of Montbéliard was rebuilt in 1751, but the Tour Bossue and the Tour Neuve, dating from 1425 and 1594, are preserved. Most of the inhabitants are Protestant, and the church of St. Martin, built early in the 17th century, now serves as a Protestant place of worship. The old market-hall and some old houses of the 16th century also remain. Montbéliard is the seat of a sub-prefect and has a board of trade arbitrators, a chamber of arts and manufactures and a museum of natural history.

After 1870 a considerable impetus was given to its prosperity by Alsatian immigrants. Its industries include watch and clock making and dependent trades, cotton spinning and weaving, the manufacture of hosiery, textile machinery, furniture, spare parts for motor cars, tools, nails and wire and brewing. There is commerce in wine, cheese, wood and Montbéliard cattle.

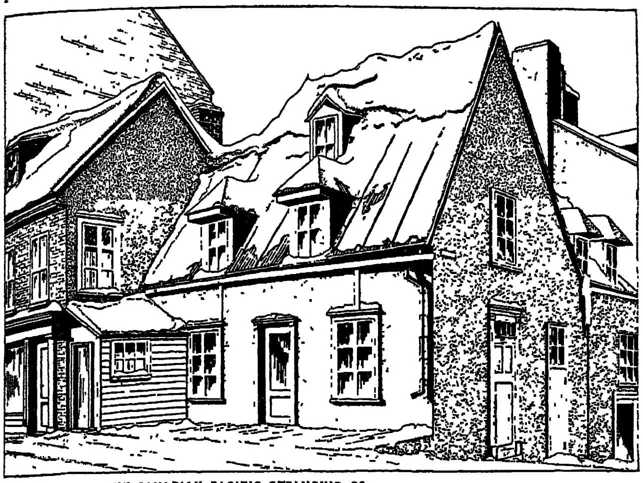
After belonging to the Burgundians and Franks, Montbéliard (*Mons Peligardi*) was, by the treaty of Verdun (843), added to Lorraine. In the 11th century it became the capital of a countship, which formed part of the second kingdom of Burgundy and latterly of the German Empire. Its German name is Mömpelgard. In 1397 it passed by marriage to the house of Württemberg, to whom it belonged till 1793. It resisted the attacks of Charles the Bold (1473), and Henry I. of Lorraine (1587 and 1588), duke of Guise, but was taken in 1676 by Marshal Luxemburg, who razed its fortifications. The tolerance of the princes of Württemberg attracted to the town at the end of the 16th century a colony of Anabaptists from Frisia. In 1793 the inhabitants voluntarily submitted to annexation by France. In 1871 the battle of the Lisaine between the French and Germans was fought in the neighbourhood and partly within the walls.

MONTBRISON, a town of east-central France, capital of an arrondissement in the department of Loire, France, 21 m. N.W. of St. Étienne, on the railway from Clermont to St. Étienne. Pop. (1926) 6,769. Montbrison belonged to the counts of Forez during the middle ages. It stands on a volcanic hill overlooking the Vizezy, a right-hand affluent of the Lignon du Nord. The principal buildings are the once collegiate church of Notre-Dame d'Espérance, founded about 1220 but not finished till the 15th century, and the 14th century building known as the Salle de la Diana (Decana), restored by Viollet-le-Duc. Montbrison is the seat of a sub-prefect, and of a tribunal of first instance. There are liqueur-distilleries, mineral waters, and flour-mills, and silk ribbons are manufactured; there is considerable commerce in grain.

MONTCALM, LOUIS-JOSEPH DE MONTCALM-GOZON, Marquis de (1712–1759), French general, born near Nîmes, on Feb. 29, 1712. He was strictly brought up under the tutorship of a kinsman, Louis Dumas, becoming a good classical scholar and the master of a vivid and nervous, though unconventional French style. At the age of 15 he received a commission in the regiment at Hainaut. He first saw active service on the Rhine in the War of the Polish Succession. In 1735 he succeeded to his father's titles and property, and in the following year married Angelique-Louise Talon du Boulay, by whom he had ten children. In 1743, during the War of the Austrian Succession, he became colonel of the regiment of Auxerrois, and three years later he distinguished himself at the battle of Piacenza, where he was wounded five times and taken prisoner. In 1747 he was raised to the rank of brigadier, and at the end of

the war given the command of a cavalry regiment. The next few years he spent with his family at Candiac; but early in 1756 he was chosen to command the French regular troops in Canada, with the rank of major-general. He reached Quebec on May 13.

Montcalm's commission gave him no authority over the greater part of the military resources of Canada, and he was in all respects subordinate to the governor-general, the Marquis de



BY COURTESY OF THE CANADIAN PACIFIC STEAMSHIP CO.

GENERAL MONTCALM'S HEADQUARTERS DURING HIS DEFENCE OF QUEBEC, 1759

Vaudreuil, who from the first was jealous, suspicious and critical. The tempers of the two were wholly incompatible, and the prospects of the colony were gravely prejudiced by their ever-increasing animosity towards each other. Montcalm was also embarrassed by the corrupt practices of a gang of government officials, headed by the intendant, François Bigot. Nevertheless, he enjoyed three years of striking success. If it was Vaudreuil who suggested the undertaking, it was Montcalm who, with great judgment and energy, forced the surrender of the English post at Oswego in the summer of 1756, thus restoring to France the undisputed control of Lake Ontario. Next year he took the offensive towards the south, and on August 9, after a siege of but five days, captured Fort William Henry, at the head of Lake George, with its garrison of 2,000 men. His victory was marred by the slaughter of many of the prisoners by his Indian allies—a catastrophe which he deplored and strove at the risk of his life to arrest, but which he might have prevented by taking a few obvious precautions.

Montcalm's greatest feat was achieved on July 8, 1758, when with about 3,800 men he repulsed the attack of Abercromby's 15,000 on the breastwork and abbatis which the French had hastily constructed at Ticonderoga. The victory, however, was due to Abercromby's stupidity as much as to Montcalm's skill; and Vaudreuil was not altogether unreasonable in criticizing him for making no attempt to exploit his success. The French had now definitely lost the initiative, and in 1759 Montcalm had to defend Quebec itself against Wolfe. As his army, though superior in numbers, was inferior in quality to his opponent's, Montcalm remained strictly on the defensive in his entrenched lines between the St. Charles and Montmorency rivers. For more than two months he baffled the besiegers, and on July 31 beat off an ill-considered attack on his works near the Montmorency Falls. In the end, however, he was outwitted, though it is fair to say that, but for Vaudreuil's interference, he would have greatly strengthened the guard near the point where the British scaled the Heights of Abraham. In the battle which followed, Montcalm behaved with conspicuous gallantry, and was mortally wounded while trying to rally his broken army. He died in Quebec next day, Sept. 14, and was buried in the chapel of the Ursuline convent.

Montcalm was a devout Catholic. He was a good husband and father, and, judged by the contemporary standards of his class, his private life was remarkably upright and honourable. His impetuous temper and hasty speech gained him many enemies, yet his personal charm and integrity usually won the affection of his associates and subordinates. His devotion to his country is beyond dispute.

Chapais, *Le Marquis de Montcalm* (1911). (W. T. W.)

MONTCEAU-LES-MINES, a town of east-central France, in the department of Saône-et-Loire, 14 m. S. by W. of Le Creusot on the P.L.M. railway. Pop. (1926) 8,109. It is the centre of the Blanzy coal basin, on the Canal du Centre, connected with the coalfield by numerous lines of railway. There are spinning, weaving and hosiery factories, iron and copper foundries and engineering shops making textile machinery.

MONT CENIS, a pass (6,893 ft.) in Savoy (France) which forms the limit between the Cottian and Graian Alps. A carriage road (1803–1810) was built across it by Napoleon, while a light railway was opened alongside the road in 1868, but was destroyed in 1871, on the opening of the tunnel. This tunnel (highest point 4,249 ft.) is really 17 m. west of the pass, below the Col de Fréjus. From Chambéry the line runs up the Isère valley, but soon bears through that of the Arc or the Maurienne past St. Jean de Maurienne to Modane (61 m. from Chambéry). The tunnel (8 m. long) leads to Bardonnèche, some way below which, at Oulx (18 m. from Modane) the line joins the road from the Mont Genèvre. Thence the valley of the Dora Riparia is followed to Turin (64½ m. from Modane). The motor road mounts the Arc valley for 16 m. from Modane to Lanslebourg, whence it is 8 m. to the hospice, a little way beyond the summit of the pass. The descent lies through the Cenis valley to Susa (37 m. from Modane) where the road joins the railway. To the south-west of the Mont Cenis is the Little Mont Cenis (7,166 ft.) which leads from the summit plateau (in Italy) of the main pass to the Étache valley (in France) and so to Bramans in the Arc valley (7 m. above Modane). This pass was crossed in 1689 by the Vaudois, and by some authors is believed to have been "Hannibal's Pass."

MONTCHRETIEN, ANTOINE DE (1575 or 1576–1621), French dramatist and economist, son of an apothecary at Falaise named Mauchrestien, was born about 1576. In one of his numerous duels he killed his opponent, and took refuge in England. Through the influence of James I., to whom he dedicated his tragedy, *L'Ecossaise,* he was allowed to return to France, and established himself at Auxonne-sur-Loire, where he set up a steel foundry. In 1621 he joined the Huguenot side in the civil wars. He raised troops in Maine and Lower Normandy, but was killed in a skirmish near Tourailles on Oct. 8, 1621. In 1615 he published a valuable *Traité de l'économie politique,* based chiefly on the works of Jean Bodin.

His dramas are *Sophonisbe* (1596), afterwards remodelled as *La Cartaginoise; L'Ecossaise, Les Lacènes, David, Aman* (in 1601); *Hector* (1604). As plays they have little technical merit, but they contain passages of great lyrical beauty.

The tragedies were edited in 1901 by M. Petit de Julleville with notice and commentary; the *Traité de l'économie politique* in 1889 by Th. Funck Brentano.

MONTCLAIR, a town of Essex county, New Jersey, U.S.A., about 15 m. N.W. of lower New York City, on the Erie and the Lackawanna railways. The population was 28,810 in 1920 (18% foreign-born white); in 1930, 42,017. It is a delightful residential suburb, on the slopes of the Orange mts., the altitude ranging from 215 to 665 feet. It has excellent public and private schools, and is the seat of a state normal school (1908). The lower part of Montclair was settled in 1675 and gradually became known as Cranetown. In 1812 Bloomfield, in which it lay, was organized as a separate township, and in 1868 West Bloomfield (as Cranetown by this time was called) together with Speertown (settled by the Dutch) was incorporated as Montclair, which in 1894 became a town.

MONT-DE-MARSAN, a town of south-west France, capital of the department of Landes at the confluence of the Midou and the Douze, 92 m. S. of Bordeaux. Pop. (1926), 9,126. Mont-de-

Marsan, the first of the Bastides (*q.v.*) of the middle ages was founded by Pierre, vicomte de Marsan, as the capital of his territory in 1141. In the 13th century it passed to the viscounts of Béarn, and was united to the French Crown on the accession of Henry IV. Most of the buildings are in the older quarter, on the peninsula between the two rivers forming the Midouze. A 14th century keep, now used for military purposes, was built by Gaston Phoebus. The town is the seat of a prefect, court of assizes and of a tribunal of first instance. The industries include distillation of turpentine and resinous oils, the founding and forging of metal, wood-sawing, and manufactures of machinery and straw envelopes for bottles. There is trade in resin, wine, brandy, timber and live stock.

MONTDIDIER, a town of northern France, capital of an arrondissement in the department of Somme, 23 m. S.E. of Amiens by rail. Pop. (1926) 4,601. The town, on a hill on the bank of the Don, dates from the Merovingian period, and perhaps owes its name to the imprisonment of the Lombard king Didier in the eighth century. Held first by its own lords, afterwards by the counts of Crépy and Valois, Montdidier passed to the Crown in the 12th century, at the end of which it was granted a charter of liberties. The town was laid in ruins during the World War. It has a sub-prefecture.

MONT-DORE-LES-BAINS, a watering-place of central France in the department of Puy-de-Dôme, situated at a height of 3,440 ft., on the right bank of the Dordogne not far from its source, and 31 m. by road S.W. of Clermont-Ferrand. Pop. (1926) 1,775. The Monts Dores close the valley towards the south. The thermal springs of Mont Dore were known to the Romans. Bicarbonate of soda, iron and arsenic are the principal ingredients. Baths of high temperature are a feature. From the elevation and exposure of the valley, the climate of Mont-Dore-les-Bains is severe, and the season only lasts from June 15 to Sept. 15.

MONTEAGLE, WILLIAM PARKER, 4TH BARON, and 11TH BARON MORLEY (1575–1622), was the eldest son of Edward Parker, 10th Baron Morley (d. 1618), and of Elizabeth, daughter and heiress of William Stanley, 3rd Baron Monteagle (d. 1581). He received knighthood when with Essex in Ireland in 1599, and in 1601 with Catesby and others, took part in the latter's rebellion in London, when he was punished by imprisonment and a fine of £8,000. In 1602 he supported the mission to Spain inviting Philip III. to invade England. However, he acquiesced in James I.'s accession and assisted the earl of Southampton in securing the Tower for the king. He was taken into favour, and received a summons to attend the parliament of Nov. 5, 1605, as Lord Monteagle. On Oct. 26, 1605, he received the celebrated letter giving warning of the gunpowder plot, probably written by Francis Tresham, Lady Monteagle's brother. After having it read aloud by Ward, a gentleman in his service and an intimate friend of Winter, one of the chief conspirators, he took it to Whitehall and showed it to Lord Salisbury and other ministers. On Nov. 4, he accompanied Lord Suffolk, the lord chamberlain, to the vault under the parliament house, where Guy Fawkes was found. Monteagle received £700 a year for his services in averting the disaster. In 1609 he was chosen a member of the council of the Virginia Company and subscribed to its funds. The same year "disorders in his house" are reported, probably referring to his harbouring of Roman Catholic students from St. Omer. In 1618, on the death of his father, he was summoned to parliament as Baron Morley and Monteagle. He died on July 1, 1622, at Great Hallingbury, Essex.

MONTEBELLO, a city of Los Angeles county, California, U.S.A., 8 m. E. of Los Angeles, on the Santa Fe and the Union Pacific railways. The population was 5,498 in 1930 by the Federal census. It lies near an oil field of the same name which was discovered in 1916, adjoins the Union Pacific Industrial Section and is the headquarters of extensive nurseries and cut-flower industries. The State Flower and Horticultural Exhibition is held here annually in October. The city was founded about 1915 and was incorporated in 1920. It is governed by a board of trustees.

MONTE CARLO: *see* MONACO.

MONTE CASSINO, an isolated hill overhanging the town of Cassino (*see* CASINUM). Hither St. Benedict migrated from Subiaco in A.D. 529, and established the monastery that became the metropolis of Western monachism. It was sacked by the Lombards (580–590), rebuilt in 720, destroyed by the Saracens in 884, and restored seventy years later. It was most influential under Desiderius (who became Pope Victor III. in 1087) and Oderisius (1059–1105). The abbot became overlord of an extensive territory and bishop of several dioceses. At the dissolution of monasteries in 1866 Monte Cassino became a national monument and the monks were recognized as custodians. There are rich archives, and a large secondary school with 250 boys.

See L. Tosti, *Storia della badia di M.C.* (1841; 2nd ed., 1888).

MONTECATINI, a much-frequented mineral spa of Tuscany, Italy, in Val di Nievole, province of Lucca, 7 m. W. by S of Pistoia, 105 ft. above sea-level. Pop. (1921) 6,319 (Bagni di Montecatini); 3,367 (Montecatini). The springs are saline, and range in temperature from 82·4° to 86° F. The water is both drunk and used for bathing by some 80,000 visitors annually, and is exported in bottles.

MONTE CORVINO, GIOVANNI DI (*c.* 1247–1328), Franciscan missionary, traveller and statesman, founder of the earliest Roman Catholic missions in India and China, and archbishop of Peking. In 1272 he was commissioned by the emperor Michael Palaeologus, to Pope Gregory X., to negotiate for the reunion of Greek and Latin churches. From 1275 to 1289 he laboured as a missionary in the Nearer and Middle East. In 1289 he was sent out as Roman legate to the Great Khan, the Ilkhan of Persia, and other leading personages of the Mongol world, as well as to the "emperor of Ethiopia" or Abyssinian negus. Arriving at Tabriz, then the chief city of Mongol Persia, and indeed of all Western Asia, Monte Corvino moved down to India to the Madras region or "Country of St. Thomas," from which he wrote home, in Dec. 1291 (or 1292), the earliest noteworthy western account of the Coromandel coast. He next appears in "Cambaliech" or Peking, and wrote letters (of Jan. 8, 1305, and Feb. 13, 1306), describing the progress of the Roman mission in the Far East, in spite of Nestorian opposition; alluding to the Roman Catholic community he had founded in India, and to an appeal he had received to preach in "Ethiopia" and dealing with overland and oversea routes to "Cathay," from the Black sea and the Persian gulf respectively. In 1303 he received his first colleague, the Franciscan Arnold of Cologne; in 1307 Pope Clement V. created him archbishop of Peking, and despatched seven bishops to consecrate and assist him; three only of these arrived (1308). Three more suffragans were sent out in 1312, of whom one at least reached East Asia. A Franciscan tradition maintains that about 1310 Monte Corvino converted the Great Khan (*i.e.*, Khaishan Kuluk, third of the Yuen dynasty; 1307–11); this has been disputed, but he unquestionably won remarkable successes in North and East China. Besides three mission stations in Peking, he established one near the present Amoy harbour, opposite Formosa. At his death, about 1328, heathen vied with Christian in honouring him. He was apparently the only effective European bishop in the Peking of the middle ages.

The mss. of Monte Corvino's *Letters* exist in the Laurentian library, Florence (for the Indian Epistle) and in the National library, Paris, 5006 Lat.—viz., the *Liber de aetatibus*, fols. 170, v.–172, r. (for the Chinese). They are printed in Wadding, *Annales minorum* (A.D. 1305 and 1306) vi. 69–72, 91–92 (ed. of 1733, etc.), and in the *Münchner gelehrte Anzeigen* (1855), No. 22, part iii. pp. 171–175. English translation, with valuable comments, are in Sir H. Yule's *Cathay*, i. 197–221. *See* also Wadding, *Annales*, v. 195–198, 199–203, vi. 93, etc., 147, etc., 176, etc., 467, etc., C. R. Beazley, *Dawn of Modern Geography* (1897 etc.) iii. 162–178, 206–210. (C. R. B.)

MONTECRISTO (anc. Oglasa), an island of Italy, belonging to the province of Leghorn, 25 m. S. of Elba (highest point 2,126 ft. above sea-level; area about 6 sq.m.). It contains the ruins of a Camaldulensian monastery, abandoned in 1553, and is the private property of the king of Italy, who has a shooting-lodge there. The fame of the island is due to *Le Comte de Montecristo,* by the elder Dumas (*q.v.*).

MONTECUCCULI, RAIMONDO, COUNT OF (1609?–1680), prince of the Holy Roman Empire and Neapolitan duke of

Melfi, Austrian general, born Feb. 2, 1608 or 1609, at the castle of Montecucculo in Modena. At the age of sixteen Montecucculi began as a private soldier under his uncle, Count Ernest Montecucculi, a distinguished Austrian general (d. 1633), but seeing continuous service in Germany and the Low Countries, he rose by 1634 to a colonelcy. In 1639 he was taken prisoner at Melnik and detained for two and a half years in Stettin and Weimar. In captivity he studied military science, geometry, history and architecture and planned his great work on war. On his release he distinguished himself again in Silesia, and in Lombardy (1643). On his return to Germany he was promoted lieutenant-field-marshal and obtained a seat in the council of war. In 1645–46 he served in Hungary, on the Danube and Neckar, and in Silesia and Bohemia. The victory of Triebel in Silesia won him the rank of general of cavalry, and at Zusmarshausen in 1648 his rearguard fighting rescued the imperialists from annihilation. For some years after the peace of Westphalia Montecucculi was chiefly concerned with the business of the council of war, though he went to Flanders and England as the representative of the emperor, and to Sweden as the envoy of the pope, and at Modena his lance was victorious in a great tourney. In 1657, soon after his marriage with Countess Margarethe Dietrichstein, he saw further active service. He became field-marshal in the imperial army, and with the Great Elector of Brandenburg completely defeated Rakoczy and his allies (peace of Oliva, 1660). From 1661 to 1664 Montecucculi defended Austria against the Turks, whom he defeated so completely at St. Gotthard Abbey, on the Raab, that they made a truce for twenty years (Aug. 1, 1664). He was given the Golden Fleece, and became president of the council of war and director of artillery. He also devoted much time to the compilation of his various works on military history and science. When the war broke out against France, he received command of the imperial forces. In 1673 he completely out-manoeuvred his great rival Turenne on the Neckar and the Rhine. He retired from the army when, in 1674, the Great Elector was appointed to command in chief, but the brilliant successes of Turenne in the winter of 1674 and 1675 brought him back. After Turenne's death Montecucculi invaded Alsace, where he engaged in a war of manoeuvre with the great Condé. The siege of Philipsburg was Montecucculi's last achievement in war. The rest of his life was spent in military administration and literary and scientific work at Vienna. In 1679 the emperor made him a prince of the empire, and shortly afterwards he received the dukedom of Melfi from the king of Naples. Montecucculi died at Linz on Oct. 16, 1680, as the result of an accident. He shared with Turenne and Condé the first place amongst European soldiers of his time. His *Memorie della guerra* profoundly influenced the age which followed his own.

AUTHORITIES.—The *Memorie della guerra,* etc., was published at Venice in 1703 and at Cologne in the following year. A Latin edition appeared in 1718, a French version in 1712, and the German *Kriegsnachrichten des Fürsten Raymundi Montecuccoli* in 1736. Many memoirs on military history, tactics, fortification, etc., written in Italian, Latin and German, remain still unedited in the archives of Vienna. The collected *Opere di Raimondo Montecuccoli* were published at Milan (1807), Turin (1821) and Venice (1840), and include political essays and poetry.

See Campori, *Raimondo Montecuccoli* (Florence, 1876); Spenholtz, *Aureum vellus seu catena,* etc. (Vienna, 1668); Paradisi, *Elogio storico del conte Raimondo Montecucculi* (Modena, 1776); Pezzl, *Lebensbeschreibung Montecucculis* (Vienna, 1792); Hormayr, *Oesterreichischer Plutarch,* XIII. (Vienna, 1808); Würzbach, *Biographisches Lexikon des Kaiserthums,* etc., pt. 19 (Vienna, 1868); *Die Hofkriegsraths, präsidenten* (Vienna, 1874); Weingärtner, *Heldenbuch* (Teschen. 1882); Grossmann, *Archiv für öst. Geschichte* (Vienna, 1878); *Allgemeine deutsche Biographie,* vol. xxii. (Leipzig, 1885). Important controversial works are those of Turpin and Warnery, two distinguished soldiers of the 18th century (*Commentaires sur les mémoires,* etc. [Paris], 1769, and *Commentaires sur les comm. . . . du comte Turpin,* Breslau, 1777). A critical estimate of Montecucculi's works will be found in Jähns *Gesch. der Kriegswissenschaften,* ii. 1162–78 (Leipzig, 1890).

MONTEFIASCONE, a town and episcopal see, province of Viterbo, Italy, built on a hill (2,077 ft.) on the S.E. side of the Lake of Bolsena, 70 m. N.W. of Rome by rail. Pop. (1921), 6,362 (town); 10,035 (commune). The cathedral (1519) is one of the earliest structures by Sammicheli. In it the Old Pretender was married to Clementine Sobieski (1719); San Flaviano (built in 1032, repaired and enlarged in the Gothic style late in the 14th century), is a curious double church.

MONTEFIORE, SIR MOSES HAIM (1784–1885), Jewish philanthropist, was born at Leghorn on Oct. 24, 1784, of a family of Jewish merchants who had settled at Ancona and Leghorn in the 17th century. His uncle purchased for him the right to practice as one of the 12 Jewish brokers licensed by the city of London, and Montefiore entered the Stock Exchange, where he amassed a fortune sufficient to enable him to retire in 1824. By his marriage with Judith, daughter of Levi Barent Cohen, whose sister was the wife of Nathan Mayer Rothschild, a close business connection between the houses of Rothschild and Montefiore was established. From his 43rd year Montefiore devoted all his energies to ameliorating the lot of his co-religionists. On his return from his first pilgrimage to Palestine in 1837, which resulted in a friendship with Mohammed Ali, Montefiore assisted the British Jews in their struggle to obtain full political and civil rights. In 1837 he became the City of London's second Jewish sheriff, and was knighted.

In 1838, accompanied by Lady Montefiore, he started on a second voyage to Palestine, in order to submit to Mohammed Ali a scheme for Jewish colonization in Syria. Though political disturbances rendered his efforts again unsuccessful, the year 1840 brought Montefiore once more before Mohammed to plead for some Jews imprisoned at Damascus. He obtained their release, and also wrung a decree from the Porte giving Jews throughout Turkey the utmost privileges accorded to aliens. In 1846 the threatened re-issue in Russia of an Imperial ukase (first promulgated in 1844) ordering the withdrawal of all Jews from within 50 versts of the German and Austrian frontiers, caused Montefiore to interview the tsar, and he succeeded in getting the ukase rescinded. On his return, Queen Victoria, on the recommendation of Sir Robert Peel, made him a baronet. In 1859 a case of injustice brought Montefiore to the gates of the Vatican, and four years later he obtained from the Sultan, Abdul Aziz, the confirmation of his predecessor's decrees in favour of the Jews. The year 1864 found him in Morocco combating an outbreak of anti-Semitism; 1866 in Syria, relieving the distress resulting from a plague of locusts and an epidemic of cholera; and 1867 in Rumania, pleading the cause of the Jews with Prince Charles. His seventh and last pilgrimage to the Holy Land was made in 1875, of which he wrote an account in his *Narrative of a Forty Days' Sojourn in the Holy Land,* published in that year. The last decade of his life was passed upon his estate near Ramsgate, in Kent, where he died on July 28, 1885. Montefiore was a strictly orthodox Jew, scrupulously observant of the Scriptures; in his grounds he had a synagogue built where services were held twice a day, a college where ten rabbis lived and expounded the Jewish law, and a mausoleum for himself and Lady Montefiore, who died in 1862.

See *The Diaries of Sir M. Montefiore and Lady Montefiore, 1812–1883* (1890, 2 vols.); Lucien Wolf, *Sir M. Montefiore* (1884); E. Wolbe, *Sir M. Montefiore* (1909).

MONTÉGUT, JEAN BAPTISTE JOSEPH ÉMILE (1825–1895), French critic, was born at Limoges on June 14, 1825 and died in Paris on Dec. 11, 1895. He began to write for the *Revue des deux mondes* in 1847, contributing between 1851 and 1857 a series of articles on the English and American novel, and in 1857 he became chief literary critic of the review. Émile Montégut translated the *Oeuvres complètes* (10 vols. 1868–73) of Shakespeare. Among his numerous critical works is *Ecrivains modernes d'Angleterre* (3rd series, 1885–92).

See A. Laborde-Milaà, *É. Montégut, 1825–1895* (1922).

MONTELEONE DI CALABRIA, city, Calabria, Italy, province of Catanzaro, on an eminence gently sloping to the Gulf of S. Eufemia, 1,575 ft. above sea-level, 70 m. N.N.E. of Reggio di Calabria by rail. Pop. (1921), 12,965 (town); 13,842 (commune). Destroyed by earthquake in 1783, under the French occupation it was rebuilt and made capital of a province. It suffered in the earthquake of 1905. The castle was built by Frederick II. The principal church contains sculptures by the Gagini of Palermo.

Monteleone is the ancient Hipponium, first mentioned in 388 B.C., when its inhabitants were removed to Syracuse by Dionysius. Restored by the Carthaginians (379), occupied by the Bruttii (356), held by Agathocles of Syracuse (294), Hipponium ultimately became, as Vibo Valentia, a flourishing Roman colony, where a branch from Scolacium (Squillace) on the east coast road joined the Via Popilia. A harbour was made by Agathocles at Bivona on the coast. In the modern town there are some Roman remains. The town walls of the Greek city can be traced for their whole extent, about 4 miles. They are well constructed of regular blocks of stone. They belong to the end of the 5th century B.C. and are the finest monument of Greek military architecture in Calabria. Important remains of them have recently been brought to light, and traces of four temples. The Roman town occupied only part of the Greek site; the streets of the modern town still preserve the Roman arrangement. (T. A.)

MONTÉLIMAR, a town of south-eastern France in the department of Drôme, near the Rhône, 93 m. S. of Lyons on the railway to Marseilles. Pop. (1926) 8,320. Montélimar was called by the Romans *Acunum*. At a later period it belonged to the family of Adhémar and received the name Monteil d'Adhémar, whence the present name. Towards the middle of the 14th century it was sold by them partly to the dauphins of Viennois and partly to the pope, and in the next century it came into the possession of the Crown. During the religious wars it valiantly resisted Gaspard de Coligny in 1570, but was taken by the Huguenots in 1587. The ancient castle is now used as a prison. Remains of the ramparts and four old gates, dating from the 14th, 15th and 16th centuries, are also preserved. The industries include tanning and the making of tiles, bricks, hats, lime, farming implements, preserved foods, nougat and wines.

MONTELIUS, OSKAR (1843–1921), Swedish archaeologist, was born in Stockholm on Sept. 9, 1843. He studied at the University of Stockholm, and took the degree of Ph.D. in 1869. In 1888 he was appointed a professor in the Museum of National Antiquities, Stockholm, and in 1913 became State archaeologist. As an archaeologist his aim was to utilize and develop the typological method explained by him in his book *Die Typologische Methode* (1903). He died at Stockholm on Nov. 5, 1921. His works include: *The Civilisation of Sweden in Heathen Times* (1888); *Les temps préhistoriques en Suède et dans les autres pays Scandinaves* (1895); *Kulturgeschichte Schwedens* (1906); and *La civilisation primitive en Italie depuis l'introduction des métaux* (3 vol. 1895–1910).

See *Oscar Montelius, in Memoriam* (Stockholm, 1922).

MONTEMAYOR or **MONTEMÔR, JORGE** (1520?–1561), Spanish novelist and poet, of Portuguese descent, was born at Montemôr o Velho (near Coimbra), whence he derived his name, the Spanish form of which is Montemayor. His reputation is based on a prose pastoral romance, the *Diana* (1559?). It is important as the first pastoral novel published in Spain; as the starting-point of a universal literary fashion; and as the indirect source, through the translation included in Googe's *Eglogs, epytaphes and sonnets* (1563), of an episode in the *Two Gentlemen of Verona*. Montemayor's mastery of Spanish is amazing, and that he pleased his own generation is proved by the 17 editions and two continuations of the *Diana* published in the 16th century, by parodies, imitations and renderings in French and English.

See G. Schönherr, *Jorge de Montmayor, sein Leben und sein Schäferroman* (Halle, 1886); H. A. Rennert, *The Spanish Pastoral Romances* (Philadelphia, 1912).

MONTENEGRO, the Black Mountain, formerly a country of south-eastern Europe, its name being the Venetian variant of the Italian *Monte Nero*. It extended between 41° 55′ and 43° 21′ N. lat., and between 18° 30′ and 20° E. long., with a seaboard of 28 m. on the Adriatic sea. It included most of the basins of the Moratcha, and its feeder, the Zeta, flowing into Lake Scutari, and that of the Piva, while the river Tara formed its north-east boundary. It was mostly difficult mountain-country, with some rich grassy uplands and small cultivable basins around Cettigne, the former village capital, and a fairly rich belt along the Zeta. The north was largely composed of forested heights among which the rivers ran in deep gorges, and to the west of Cettigne stands Mount Lovchen (5,633 ft.), the dark mountain which is the reason for the country's name and the centre of the region's history because it was an asylum for the Serbian nobles after the defeat by the Turks at Kossovo (1389). *See* YUGOSLAVIA.

HISTORY

Mediaeval Period.—Crna Gora, the Black Mountain, better known as Montenegro, which did not become a separate unit of its own till the 14th century, was really a development from one of the earliest of Serb state formations, the so-called Zeta, which comprised the districts round the river of that name, with Skutari and its lake, the Bocche di Cattaro, and a part of what was afterwards Hercegovina. It gradually came to be merged in the mediaeval Serbian State under the Nemanja dynasty (*q.v.*), though retaining a certain rude autonomy under Župans of its own. After the death of Tsar Dušan (1356) the central authority weakened, and a number of great feudal lords asserted their independence. While King Vukašin and Marko Kraljević ruled in part of Macedonia, and Stephen Vukčić established the Duchy of St. Sava, the Balša family, cousins of Tsar Uroš, asserted control in the Zeta, holding Skutari and Dulcigno as their two chief strongholds. The Balša ruled from about 1358 to 1421, offering a refuge in their mountains to Serbs flying from the Turkish advance, and on the other side holding in check the designs of Venice on the Southern Adriatic. They were succeeded by another Serbian dynasty, the Crnojević, which was related to the Albanian hero Scanderbeg, and also allied itself with Venetian patrician families. As the Turks successively conquered Serbia, Bosnia and Albania, the Black Mountain found itself in a position of growing isolation. In 1479 the Venetians surrendered Skutari to the Porte, in 1482 Hercegovina was overrun, and in 1484 Ivo the Black was obliged to burn his tiny capital at Žabljak on the north-eastern shore of the Lake of Skutari, and to withdraw to the more inaccessible village of Cetinje, perched beneath the great peak of Lovčen. Here Ivo laid the independence of Montenegro, founded a monastery and bishopric and won a name in legend and popular poetry, as a kind of Barbarossa or Boabdil who after long slumber in the bowels of the mountain would one day come forth to free the Serbian race. The spirit animating Ivo and his followers is revealed in the law which prescribed that any man leaving the field of battle without orders or showing signs of fear, should be dressed as a woman and then driven by the real women out of the country, as a coward and a traitor. Yet these broken men were not untouched by the new culture from the west: for Ivo's son George bought a printing press from the Venetians and erected it at Obod, where some of the earliest Slav books were printed. Only too soon it had to be melted down to provide leaden bullets against the Turks.

Montenegro Under the Vladikas.—The last Crnojevič resigned office in 1516, and from that date till 1696 the mountaineers were ruled by their Vladikas or Bishops, elected by popular assemblies and consecrated by the Serbian Patriarch of Peć (Ipek). This was a period of perpetual warfare with the Turks and of periodic invasion, Cetinje being captured in 1623 and 1687. By the close of the 17th century Muslim intruders were beginning to levy dues upon the peasants, mosques were being built and there was a certain apostasy to Islam. In 1697 the irreconcilables met the growing danger by granting to the Vladika, Danilo Petrović of Njegoš, the right to select his successor among his own kin and thus found a new dynasty. In 1700 he received consecration from the Serbian Patriarch at his new home in Karlovci (Karlowitz) and in 1702 organized the famous "Montenegrin Vespers," by which almost all the Muslims were massacred and their few survivors forced to be rebaptized. Danilo was the first to establish those relations with Russia which were to become a tradition of his family, and in 1711 took up arms against the Turks at the instance of Peter the Great, with the result that Cetinje was sacked for the third time. In 1716 Danilo visited St. Petersburg and obtained an annual subsidy from the tsar. His two successors Sava and Vasili also paid visits to Russia, and on the latter's death there, in 1766, an impostor named Stephen

the Little obtained the throne of Montenegro by claiming to be the murdered Tsar Peter III., so strong was the appeal of Slav sentiment. After Stephen's murder in 1774 the aged Sava resumed office. His nephew Peter I. (1782–1830), the greatest of the Vladikas, again joined Russia in war upon the Turks, from 1787 onwards, but after peace was left alone to face their vengeance. In 1796 at Krusi he won a great victory over the vizier of Skutari, whose head was long preserved as a trophy in the monastery of Cetinje. After Austerlitz he co-operated with the Russian fleet against the French in Dalmatia and laid siege to Ragusa: but he failed in his design of acquiring the Bocche di Cattaro, which fell to Austria in 1814. At home Peter I. discouraged the blood feud and introduced a rough code of law, and the rudiments of an administration. After his death he was canonized by popular sentiment. His nephew Peter II. (1830–51) was not only remarkable as warrior and statesman, but is recognized as the greatest of Serbian poets (for his two epics "The Mountain Garland" and "Light of the Microcosm"). He established a senate in 1831, was interested in education and showed his belief in national unity by cordial relations with Alexander of Serbia and Ban Jelačić of Croatia. He was buried on the summit of Mount Lovčen.

Nicholas I.—His nephew Danilo II. on accession divested himself of the episcopal office and became Gospodar, or Lord. He twice defended Montenegro against the Turks, defeating them near Ostrog in 1853 and at Grahovo in 1858, thus vindicating that independence which the Porte had challenged. On Aug. 11, 1860, he was murdered at Persano, by an act of private revenge, and was succeeded by his nephew Nicholas (*q.v.*), who in 1862 had to defend his country against a fresh Turkish invasion. In the 14 years of peace that followed he began to transform the rude clan levies into a modern army, and helped by Russian subsidies, established the first secondary schools. In 1868 he granted to Montenegro her first constitution, with a premier and a Cabinet of five: but he remained an autocrat, with full control of policy and revenue, and grew rich at the country's expense. In 1869 he with difficulty held back his people from helping the rising of the Krivošije against Austria: but when in 1875 Hercegovina and Bosnia revolted against the Turks, similar tactics became impossible, and early in July 1876 he and prince Milan of Serbia jointly declared war on behalf of the insurgents. Though more successful than Serbia—he occupied Nikšić and reached the coast at Antivari—he was obliged to conclude an armistice in November, and to await the decision of the Great Powers. The Treaty of Berlin assigned to Montenegro Nikšić, Podgorica, Antivari, Plava and Gusinje: but owing to the stout resistance of the Muslim and Albanian population of the two latter places they were, by a subsequent decision of the Powers (April 18, 1880), restored to Turkey, while the Hoti and most of the Klementi tribes were given to Montenegro. This also proved incapable of execution, and in the end Montenegro received Dulcigno in exchange for Plava and Gusinje. The new settlement could only be enforced after an international fleet under Admiral Seymour had appeared before Dulcigno and after the Turks had reduced the Albanian recalcitrants to order. The Treaty of Berlin contained further clauses restricting Montenegro's right to build ships and railways and placing the maritime control of her coasts in Austria-Hungary's hands: while that Power's occupation of the Sandjak kept Montenegro and Serbia artificially separate for another 34 years.

For 30 years Montenegro enjoyed profound peace under the autocratic rule of Prince Nicholas, who in 1896 celebrated the second centenary of his dynasty and allied himself by marriage with the Russian and Italian dynasties, his fourth daughter Helen becoming Queen of Italy in 1900. In 1900 Nicholas assumed the title of Royal Highness, and on August 28, 1910, proclaimed himself king. In the late '80s he was greeted by Tsar Alexander III. in a public toast as Russia's only friend in Europe: and his Russophil tendencies grew more marked as Milan Obrenović of Serbia threw himself into the arms of Austria-Hungary. It was Russia who arranged the marriage of Nicholas's daughter Zorka with Prince Peter, the exiled head of the rival Karagjorgjević dynasty: and their son Alexander, afterwards king of Yugoslavia, was born at Cetinje. Nicholas had shown his Slav sympathies in early life, and followed the literary tradition of his granduncle by composing a drama entitled *The Empress of the Balkans*, and the popular song "Onamo, 'Namo," with its dream of reoccupying the lost lands of the Serb. As an old man he undoubtedly dreamt of supplanting the Karagjorgjević and uniting the race under the Petrović dynasty.

The Balkan Wars and World War 1912–18.—The great poverty of Montenegro, in marked contrast to the relative wealth of its ruler, led to unrest and emigration: even in normal times it could not produce enough grain for its scanty population. In 1905 Nicholas found it advisable to proclaim a new constitution, providing a parliament of 76 members (14 nominated) but leaving the manner of election to the Ministry of Interior, which thus ordered public voting and exercised great pressure. At first the Progressives under Radulović were allowed to take office, but their reforming zeal at home and their advocacy of union with Serbia soon led to a breach with the prince, who dissolved parliament and henceforth governed by creatures of his own. In 1908 followed the famous Cetinje Bomb Trial, which aimed at discrediting the unionist movement, and which, though remaining a mystery, was known to have had connections with the Zagreb Treason Trial of the following year. Nicholas's assumption of the royal title in 1910 was intended as a fresh move against Serbia, but the course of Balkan events after the Turkish Revolution soon made co-operation between Cetinje and Belgrade again inevitable. Indeed Montenegro not merely joined the Balkan League, but was the first to declare war upon Turkey in October 1912. The lack of heavy guns and the imperfect discipline of his gallant troops compelled Nicholas to resort to Serbian military aid on a considerable scale, before Scutari could be reduced in April 1913. Austria-Hungary insisted upon the surrender of Scutari to the new Albania, and threatened war. Nicholas only yielded to an international naval blockade of the Montenegrin coast, and Serbian troops were withdrawn from the Adriatic. The first Balkan war gave Montenegro and Serbia a joint frontier, the former Sanjak of Novi Pazar being partitioned between them; and Montenegrin troops joined Serbia against Bulgaria in the second Balkan war. Early in 1914 the Montenegrin statesman, Miušković, began serious discussions with Pašić for a financial and customs union between Serbia and Montenegro, a fusion of the two armies, a joint foreign policy and diplomatic representation, but retention of the two dynasties.

These negotiations became known to Vienna, who warned Petrograd that "Austria-Hungary would not remain a silent observer," and regarded union as a challenge to her Adriatic interests. On this, Sazonov advised Pašić to postpone the negotiations. But the movement for union was rapidly becoming irresistible when the World War broke out and the two States found themselves side by side in resistance to Austria-Hungary. Prince Nicholas and his sons were, however, jealous and reserved, blocking the action of the Serbian General Janković, who had been sent at Russia's instance to reorganize the Montenegrin army. In May 1915 Prince Peter had a secret meeting in Dalmatia with the former Austro-Hungarian military attaché, Hubka, and in November, during the invasion of Serbia, Crown Prince Danilo, through his friend Baron de Kruyff in Sofia, made overtures to the Central Powers, offering to cut off the Serbian retreat to the coast in return for territorial concessions to Montenegro in western Serbia and northern Albania.

During the retreat the attitude of the Montenegrin dynasty remained highly equivocal, and the key position of Mount Lovčen was surrendered to the Austrians almost without a struggle. Parliament voted unanimously in favour of holding out to the end with Serbia, but the king negotiated on his own initiative without authorization from his Government, and on Jan. 1916 addressed a telegram of submission to Francis Joseph. Failing to obtain the terms which he had hoped, he and his family, with the premier Miušković, fled to Italy. During the next two years his second son, Prince Mirko, intrigued in Vienna and was connected with various Austrophil projects for a vassal Yugoslav state under the Petrović dynasty; he died in 1918 in an Austrian sanatorium. Meanwhile, King Nicholas resided in France and tried to silence

criticism from the Left by making Radović his premier. But when the latter advocated the formal proclamation of union and a simultaneous abdication of Nicholas and Peter in favour of the Prince Regent Alexander, Nicholas threw himself definitely into the arms of the anti-unionists, and by the end of the war found his court reduced to a tiny clique of personal dependents and adventurers.

Union with Serbia.—When Austria-Hungary collapsed in October 1918 and national councils were erected in all the Yugoslav provinces, the current in Montenegro set more strongly than ever in favour of union. A National Assembly was convoked on November 12 at Podgorica and proclaimed the deposition of the Petrović dynasty and the union of Montenegro with Serbia. On the death of Nicholas the royal title fell into abeyance, as Crown Prince Danilo did not wish to assume it and his nephew Michael was a minor.

The long strain of war increased the already chronic misery tenfold, and acute discontent was aroused by the bad administration, favouritism and centralist tendencies of Belgrade. There were numerous cases of brigandage and party vengeance which were conveniently misrepresented abroad as a movement for independence. In 1924, however, a marked improvement began. In the summer of 1925 King Alexander paid his first official visit to Montenegro, and the remains of his great-great-grand-uncle the Vladika Peter (the greatest of Serbian poets) were transferred to a mausoleum built at the king's expense on the summit of Lovčen by the Dalmatian sculptor Meštrović. MONTE OLIVETO MAGGIORE: *see* ASCIANO.

MONTEPULCIANO, town and episcopal see, province of Siena, Tuscany, Italy, 44 m. S.E. of it by rail. Pop. (1921), 5,537 (town); 15,959 (commune). The town, 6 m. W. of the station, crowns the summit of a hill (1,984 ft.), and is surrounded by mediaeval walls. Protected by Siena till 1202, it declared for Florence and thenceforward passed from one mistress to the other, until it finally became Florentine (1559). Most of the buildings belong to the Renaissance, except the castle and the 14th-century Palazzo Pubblico. There are fine private houses by Antonio da Sangallo the elder (1455?–1534), Baldassare Peruzzi (1481–1536) and Vignola (1507–1573). The beautiful church of S. Biagio—Sangallo's masterpiece—was built in 1518–45. The cathedral built by Bartolommeo Ammanati (1570), contains a large altar-piece by Taddeo di Bartolo of Siena, and the fragments of the tomb of Bartolommeo Aragazzi, secretary of Pope Martin V., erected by Michelozzo (1427–36). Montepulciano is famous for its wine, and was the birthplace of Politian (*q.v.*) and of Cardinal Bellarmine (1542–1621).

See F. Bargagli-Petrucci, *Montepulciano, Chiusi, &c.* (Bergamo, 1907).

MONTEREAU, a town of northern France, in the department of Seine-et-Marne at the confluence of the Yonne with the Seine, 21 m. S.E. of Melun by rail. Pop. (1926) 8,917. The 13th century church has a façade of the Renaissance period. The industries include the manufacture of porcelain, fire-proof and decorative bricks, boots and shoes and agricultural machines and colours and varnish, and trade is in grain, cattle and agricultural produce. Among the institutions are a tribunal of commerce and a chamber of arts and manufactures. Montereau in the beginning of the 15th century was of some importance. Here, on the bridge over the Yonne, Jean Sans-Peur, duke of Burgundy, was assassinated in the presence of the Dauphin, afterwards Charles VII., in 1419. In 1438 the town was captured by Charles VII., and during the wars of religion it was several times taken and retaken. In 1814 Napoleon gained a victory at Montereau over the Würtemberg troops under Schwarzenberg.

MONTEREY, a city of Monterey county, California, U.S.A., 90 m. S. by E. of San Francisco, at the south-east extremity of Monterey bay, a deep indentation of the coast, 22 m. across from headland to headland and 10 m. wide. It is served by the Southern Pacific railway and (for freight) by coastwise steamship lines other communities on the peninsula. The Presidio of Monterey, is the centre of many historic associations, and since 1881, when the Southern Pacific company built the Del Monte hotel (in the midst of beautiful and extensive grounds, a mile or so to the east), the city, and the rest of the peninsula, have been one of the favourite year-round resorts of the coast. Rocky shores crowned with ancient twisted cypresses and pines, ocean and bays on three sides and sloping tree-clad hills, provide great natural beauty, and the climate is mild and equable, rarely reaching a temperature below freezing or above 80 F. Many artists and writers have their homes here, and at Carmel-by-the-Sea, Pacific Grove, and the other communities on the peninsula. The Presidio of Monterey, partly within the city limits, is an important U.S. army post. The waters of Monterey bay have a great variety and abundance of fish. A fleet of over 100 small boats is engaged in the fishing industry, and there are sardine canneries in the city. The sardine catch in 1927 was 173,881,177 pounds. The commerce of the harbour (381,374 tons in 1925, valued at $19,747,214) is increasing. A municipal wharf was built in 1925. Since 1925 the city has had commission-manager government. Pop. 1930, 9,141.

History.—Monterey Bay was discovered by Viscaino in 1602 and named after the then viceroy of New Spain, and in May 1770, it was rediscovered by Father Junípero Serra and Capt. Gaspar de Portolá. The Franciscan mission of San Carlos was founded here on June 3, 1770. It was moved almost immediately to Carmel valley, where Father Junípero built the church in which his remains now rest. A *presidio* was completed in 1778. Until the coming of the Americans Monterey was the gayest and most ambitious city of California, the principal military, commercial and financial centre. In 1818 it was captured and held briefly by a Buenos Aires privateer. It played an important part in the jealousies that divided the northern and the southern settlements. Except for a short time (1845–47) it was the capital of California until the constitution of the new State was adopted in 1849. It was the county seat until 1872. After the discovery of gold its importance declined and San Francisco took the leading place. The flag of the United States was raised over Monterey for a day in 1842, and again, permanently, on July 7, 1846. The first American newspaper on the coast was published here, and here (in Colton hall in Sept. 1849) met the convention which framed the first Constitution of the State. Colton hall is now used as the city-hall. The first theatre in California, the first brick house and the first house of planed lumber, were built here, and are still standing, as is also the old custom house, which has flown the flags of Spain, Mexico and the United States.

MONTERO RIOS, EUGENIO (1832–1914), Spanish politician, was born at Santiago de Compostela, Corunna, Nov. 13, 1832. In 1864 he was appointed professor of canon law at the university of Madrid, and in 1869 entered the Cortes. He followed Ruiz Zorilla and as Minister of Justice in General Prim's Cabinet he introduced a number of important judicial reforms and drew up the act of abdication of King Amadeo. In 1881 he helped to found the Radical party and became Minister of Justice in 1889. From 1894–5 he was president of the Senate. He was chief of the Spanish delegation which negotiated the Treaty of Paris with the United States at the close of the Spanish-American War of 1898. In 1899 he was again president of the Senate. In 1903 he was elected leader of the Liberal party and in 1905 became Prime Minister. He resigned the leadership of the Liberal party in 1906 and was president of the Senate for the third time from 1909–14. He died at Madrid on May 12, 1914.

MONTERREY, capital of Nuevo Léon, on the Santa Catalina river, 45 m. N.E. of Saltillo, Mexico. At this strongly fortified city, on Sept. 19–24, 1846, occurred one of the hardest fought battles of the war between Mexico and the United States (1846–48). Some 10,000 Mexicans under Gen. Ampudia gar-

risoned Monterrey, against which 3,080 American regulars and 3,150 volunteers commanded by Maj.-Gen. Zachary Taylor advanced. As the Americans approached the town (Sept. 19) they were greeted by a sharp fire. To reduce the stronghold they were equipped with only 4 field batteries, a 24 lb. howitzer and one 10 in. mortar, but information revealed that the western end of the city was vulnerable in flank. Colonel Worth, with about 2,000 men, advanced to that quarter in order to turn Independence Hill and occupy the Saltillo highway, which was the only avenue of retreat southward for the Mexicans. Having moved forward about 7 m. through thick country he was stopped by darkness and a heavy storm. The next day he repulsed a charge of Mexican cavalry, assaulted Federation Ridge, took three forts, and succeeded in sending forward to Independence Hill, the main flank position, about 500 regulars. Meanwhile, at the eastern end of the city, Taylor had not succeeded so well. Col. Garland, being sent forward with little more direction than that he should take his column off to the left, advanced through fields, thickets and crooked streets in the face of a withering fire. The American artillery could do little execution and the units without much centralized leadership were separated. At a crucial moment, however, Col. Jefferson Davis led a charge that took the principal outlying fortress, but the First Ohio regiment farther to the right had to retreat with heavy loss. On the western side of the town, Worth's troops, having crouched at the base of Independence Hill all night in the rain and cold, quietly crawled at dawn toward the summit, where they took the crest and sent the garrison fleeing (Sept. 22). The next morning Col. Quitman, who was occupying the captured works on the east side of the town, started an attack from house to house on his own initiative. Hearing Worth's cannon, which had been dragged to the top of Independence Hill, firing with effect, Quitman's scattered men closed in. Worth, now feeling from the firing heard from Quitman's troops that a general engagement was taking place, started toward the town. Leaving a force to guard the Saltillo highway, he had his men with pickaxes, crowbars and shells with fuses, work from house to house. At noon both sides, weary of the struggle, rested. Night fell with the Mexicans cooped in the Plaza. When the morning came (Sept. 24) the Ohio volunteers, who had taken the place of Quitman's troops, prepared to renew hostilities when a bugle in front sounded a parley. Ampudia proposed an armistice, to which Taylor acceded. In consideration of the receipt of the city by the Americans, the Mexicans were allowed to retain their individual arms, ammunition and six field pieces. The American loss had been heavier than that of the Mexicans.

MONTE SAN GIULIANO, town and episcopal see, Sicily, province of Trapani, 2 m. E.N.E. of it, on the summit of an isolated bare hill, which rises 2,465 ft. above the sea. Pop. of commune (1921), 31,148; of town, 13,404. The town occupies the site of the ancient Eryx, a city of the Elymi. (*See* Sicily.) It was famous for the temple of Venus Erycina on the summit of the mountain. The town was seized by Pyrrhus in 278 B.C., and by Hamilcar Barcas in 243–241, and was ceded to Rome at the end of the First Punic War. In Roman times the temple possessed territory of its own, and a considerable number of female slaves. Eryx was the residence of the quaestor of the western half of the island, and Verres spent some time here. Considerable portions of the city wall (a Roman reconstruction), are preserved on the north-west (on the east and south are precipitous cliffs). The mediaeval castle, with three lofty towers guarding the entrance, occupies the south-eastern extremity of the town. The cathedral (1314), has a fine porch and Gothic façade.

See J. Kromayer, *Antike Schlachtfelder* iii. 1 (Berlin, 1912), who maintains that the present town occupies only the acropolis, and that the city, which was occupied by Hamilcar, lay further to the north-west.

MONTE SANT' ANGELO, a town of Apulia, Italy, province of Foggia, 10 m. N. of Manfredonia by road, 2,765 ft. above sea-level, on the southern slopes of Monte Gargano. Pop. (1921), 21,547 (town); 23,573 (commune). It has a ruined Norman castle and a famous sanctuary of S. Michele, founded in 491 over a cave in which the archangel is said to have appeared to S. Laurentius, archbishop of Sipontum; the bronze doors, made in Constantinople, bear the date 1076. The octagonal campanile dates from 1273. The portal of S. Maria Maggiore is noteworthy. The Tomba di Rotari is a domed building of the Norman period.

See S. Beltramelli, *Il Gargano* (Bergamo, 1907), well illustrated.

MONTESPAN, FRANÇOISE-ATHÉNAÏS DE PARDAILLAN, Marquise de (1641–1707), mistress of Louis XIV., was born at the château of Tonnay-Charente (Charente-Inférieure) the daughter of Gabriel de Rochechouart, duc de Montmartre. In 1661 she became maid-of-honour to Queen Maria Theresa, and two years later she married L. H. de Pardaillan de Gondrin, marquis de Montespan, by whom she had two children. A beautiful and brilliant woman, she became mistress of Louis XIV. in 1667. The first of the seven children Mme. de Montespan bore to the king was born in March 1669, and was entrusted to Mme. Scarron, the future Mme. de Maintenon, who acted as companion to Mme. de Montespan while the king was away at the wars. The eldest, Louis Auguste, became duc de Maine, the second, Louis César, comte de Vexin, and the third, Louise Françoise, demoiselle de Nantes (afterwards duchesse de Bourbon). These children were all legitimatized in 1673. When Louis's affection showed signs of cooling, Mme. de Montespan resorted to magic. The frequent occurrence of her maid's name in the evidence before the Chambre Ardente threw suspicion on her connection with La Voisin, but the affair was hushed up. (*See* La Voisin, C., for an account of the poisoning affair.)

In 1691, Mme. de Montespan retired to the Convent of St. Joseph with a pension of half a million francs, and honours for the members of her family. She was a generous patron of letters, and befriended Corneille, Racine and La Fontaine. She died at Bourbon l'Archambault on May 27, 1707.

Funck-Brentano, *Le Drame des Poisons* (1899); A. Durand, "Un épisode du grand règne," in *Rev. des questions hist.* (Paris, 1868); the contemporary memoirs of Mme. de Sévigné, of Saint-Simon, of Bussy-Rabutin and others; also the proceedings of the Chambre Ardente preserved in the *Archives de la Bastille* (Arsenal library) and the notes of La Reynie preserved in the Bibliothèque Nationale. She figures in V. Sardou's play, *L'Affaire des poisons* (1907).

MONTESQUIEU, CHARLES LOUIS DE SECONDAT, Baron de la Brede et de (1689–1755), French philosophical historian, was born at the château of La Brède, near Bordeaux, in January 1689. His mother was Marie Françoise de Penel, the heiress of a Gascon-English family. She had brought La Brède as a dowry to his father, Jacques de Secondat, a member of a good if not extremely ancient house, which seems first to have risen to importance in the early days of the 16th century. The title of Montesquieu came from his uncle, Jean Baptiste de Secondat, "président à mortier" in the parliament of Bordeaux—an important office, which, as well as his title, he left to his nephew. Montesquieu was in his youth known as M. de la Brède. His mother died when he was seven years old. The boy was educated at the Oratorian school of Juilly, near Meaux, and afterwards at Bordeaux. His father died in 1713, and a year later Montesquieu was admitted counsellor of the parlement. In 1715 he married Jeanne Lartigue, an heiress, plain, somewhat ill-educated, and a Protestant. They appear to have lived on good terms. In 1716 his uncle died, leaving him his name, his important judicial office and his whole fortune.

He continued to hold his presidency for twelve years, and he contributed papers on philosophy, politics and natural science to the Bordeaux Academy. During the earlier years of his presidency he finished the *Lettres persanes,* printed anonymously at Amsterdam, 1721, though Cologne appears on the title-page. In the guise of letters written by and to two Persians of distinction travelling in Europe, Montesquieu satirized unmercifully the social, political, ecclesiastical and literary follies of his day in

France, and indulged in a great deal of the free writing which was characteristic of the tale-tellers of the time. But what scandalized grave and precise readers naturally attracted the majority, and the *Lettres persanes* were very popular, passing, it is said, through four editions within the year, besides piracies. Then the vogue suddenly ceased, or at least editions ceased for nearly nine years to appear. Possibly a formal ministerial prohibition was the cause of this; for, though the regent and Guillaume Dubois must have enjoyed the book thoroughly, they were both shrewd enough to perceive that underneath its playful exterior there lay a spirit of very inconvenient criticism of abuses in church and state. The fact is that the *Lettres persanes* is the first book of what is called the Philosophe movement. It is amusing to find Voltaire describing the *Lettres* as a "trumpery book," a "book which anybody might have written easily." It is not certain that, in its peculiar mixture of light badinage with serious purpose and moderation, Voltaire could have written it himself, and it is certain that no one else at that time could.

Montesquieu composed for, or at any rate contributed to, one of the coteries of the day the clever *Dialogue de Sylla et d' Eucrate,* in which the dictator gives an apology for his conduct. For Mlle. de Clermont he wrote the curious prose-poem of the *Temple de Gnide.* A later *jeu d'esprit* of the same kind, which is almost but not quite certainly Montesquieu's, is the *Voyage à Paphos,* in which his warmest admirers have found little to praise. In 1725 Montesquieu was elected a member of the Academy, but an almost obsolete rule requiring residence in Paris was appealed to, and the election was annulled. In 1726 Montesquieu sold the life-tenure of his Bordeaux office, reserving the reversion for his son, and went to live in the capital, returning, however, for half of each year to La Brède. Fleury, a precisian in many ways, was shocked by the *Lettres Persanes,* and his opposition had to be overcome before Montesquieu was admitted, in January 1728, to the Academy.

Almost immediately afterwards he started on a tour through Europe to observe men, things and constitutions. He travelled through Austria to Hungary, but was unable to visit Turkey as he had proposed. Then he made for Italy, where he met Chesterfield. At Venice, and elsewhere in Italy, he remained nearly a year, and then journeyed by way of Piedmont and the Rhine to England. Here he stayed for some eighteen months, and acquired an admiration for English character and polity which never afterwards deserted him. He returned, not to Paris, but to La Brède, and to outward appearance might have seemed to be settling down as a squire. He altered his park in the English fashion, made sedulous inquiries into his own genealogy, arranged an entail, asserted, though not harshly, his seignorial rights, kept poachers in awe and so forth. But in his great study at La Brède (a hall rather than a study, some 60 ft. long by 40 wide) he was constantly dictating, making abstracts, revising essays, and in other ways preparing his main book. He may have thought it wise to soften the transition from the *Lettres persanes* to the *Esprit des lois,* by interposing a publication graver than the former and less elaborate than the latter. The *Considérations sur les causes de la grandeur et de la décadence des Romains* appeared in 1734 at Amsterdam, without the author's name. This, however, was perfectly well known; indeed, Montesquieu formally presented a copy to the French Academy.

But the author's reputation as a jester stuck to him, and the salons affected to consider the *Lettres persanes* and the new book respectively as the "grandeur" and the "décadence de" M. de Montesquieu; but more serious readers at once perceived its extraordinary merit, and it was eagerly read abroad. A copy annotated by Frederick the Great, was abstracted from the Potsdam library by Napoleon. The book is (putting Bossuet and Giovanni Vico aside) almost the first important essay in the philosophy of history. The point of view is entirely different from that of Bossuet, and it seems entirely improbable that Montesquieu knew anything of Vico. It is grave and destitute of ornament, but extraordinarily luminous. Printed in large type with tolerably abundant notes, it fills but two hundred pages in the standard edition of Montesquieu's works. But no work of the century, except Turgot's second Sorbonne *Discours,* contains, in proportion to its size, more weighty and original thought on historical subjects, while Montesquieu has over Turgot the immense advantage of style.

Montesquieu, though he was now advanced with his magnum opus, *L'Esprit des Lois,* published in the interim new editions of his earlier works, and made frequent visits to Paris. He did not begin the final task of composition till 1743. Two years of uninterrupted work at La Brède finished the greater part of it, and two more the rest. It was finally published at Geneva in the autumn of 1748, in two volumes quarto. Before publication Montesquieu summoned a committee of friends, according to a very common practice, to hear and give an opinion on his work. It consisted of Hénault, Helvétius, the financier Etienne de Silhouette, the dramatist Saurin, Crébillon the younger, and Fontenelle. They unanimously advised the author not to publish a book which has been described as "one of the most important books ever written," and which may be almost certainly ranked as the greatest book of the French 18th century.

Montesquieu, of course, did not take his friends' advice. The *Esprit des lois* represents the reflections of a singularly clear, original, and comprehensive mind, corrected by forty years' study of men and books, arranged in accordance with a long deliberated plan, and couched in language of remarkable freshness and idiosyncrasy. In the original editions the full title runs *L'Esprit des lois: ou du rapport que les lois doivent avoir avec la constitution de chaque gouvernement, les mœurs, le climat, la religion, le commerce, etc.* It consists of thirty-one books, which in some editions are grouped in six parts. Speaking summarily, the first part, containing eight books, deals with law in general and with forms of government; the second, containing five, with military arrangements, with taxation, etc.; the third, containing six, with manners and customs, and their dependence on climatic conditions; the fourth, containing four, with economic matters; and the fifth, containing three, with religion. The last five books, forming a kind of supplement, deal specially with Roman, French and feudal law. The spirit of moderation which distinguishes its views on politics and religion was indeed rather against it than in its favour in France, and Helvétius had definitely assigned this as the reason of his unfavourable judgment. On the other hand, if not destructive it was sufficiently critical, and it raised enemies on more than one side. The book (not altogether with the goodwill of the pope) was put on the Index, and the Sorbonne projected, though it did not carry out, a regular censure. Opposition gradually died away; even Voltaire, who was his decided enemy, was forced at length to speak in public, if not in private, complimentarily of the *Esprit,* and from all parts of Europe the news of success arrived.

Montesquieu enjoyed his triumph rather at La Brède than at Paris. He spent much of his later years in the country, though he sometimes visited Paris, and on one visit procured the release of his admirer La Beaumelle from an imprisonment which La Beaumelle had suffered at the instance of Voltaire. The curious little romance of *Arsace et Isménie,* a short and unfinished treatise on Taste, many of his published *Pensées,* and much unpublished matter date from the period subsequent to the *Esprit des lois.* At the end of 1754 he visited Paris, with the intention of getting rid of the lease of his house there and finally retiring to La Brède. He died on Feb. 10, 1755, and was buried in the church of St. Sulpice.

At the beginning of the next century the vicomte de Bonald classed Montesquieu with Racine and Bossuet, as the object of a "religious veneration" among Frenchmen. The statement requires qualification; it is true of the moderate reforming party in France of the generation after the death of Montesquieu. Professor Saintsbury has said that "the real importance of the *Esprit des lois,* however, is not that of a formal treatise on law, or even on polity. It is that of an assemblage of the most fertile, original and inspiriting views on legal and political subjects, put in language of singular suggestiveness and vigour, illustrated by examples which are always apt and luminous, permeated by the spirit of temperate and tolerant desire for human improvement and happi-

ness, and almost unique in its entire freedom at once from doctrinairism, from visionary enthusiasm, from egotism, and from an undue spirit of system."

The best edition of Montesquieu is that of Edouard Laboulaye (7 vols., Paris, 1875–79), the best biography that of Louis Vian (Paris, 2nd ed., 1879). There is a good modern edition of the *Lettres persanes* by H. Backhausen (2 vols., 1913), for the *Soc. des textes français modernes.* The bibliography of Montesquieu was dealt with by L. Dangeau in 1874. There is known to exist at La Brède a great mass of MS. materials for the *Esprit des lois,* additional *Lettres persanes,* essays, and fragments of all kinds, diaries, letters, notebooks and so forth; in 1891 Baron Charles de Montesquieu published *Deux opuscules* of his ancestors, and in 1899 Baron Gaston de Montesquieu added *Pensées,* etc. See *Correspondance de Montesquieu* ed. F. Gebelin and A. Morize (2 vols., 1914); also Ch. Oudin, *Le Spinozisme de Montesquieu* (1911); and H. Knust, *Montesquieu und die Verfassungen der Vereinigten Staaten von Amerika* (Munich, 1922).

MONTESSORI, MARIA (1869–   ), Italian educationist, was born at Chiaravalle near Ancona. She studied at the University of Rome and graduated in medicine in 1894, being the first woman in Italy to do so. She then took up the subject of educating defective children. From the experience thus acquired, she came to the conclusion that similar methods might be applied to normal children of a lower age, and after a series of experiments on a small scale she extended them to a large number of children in certain private and public infant schools in Rome. Dr. Montessori encountered a good deal of opposition from advocates of orthodox methods in education who regarded her system as destructive of discipline. At the same time she was warmly supported by a certain number of enthusiastic reformers. From 1900 to 1907 Dr. Montessori lectured on pedagogical anthropology at the University of Rome and in 1922 was appointed Government inspector of schools in Italy. Her ideas on education are set forth in *The Montessori Method* (1912), which has been translated into English and other languages. (*See* EDUCATION; MONTESSORI SYSTEM.)

MONTESSORI SYSTEM. The Montessori method is a system of education originated by Dr. Maria Montessori, an Italian doctor of the University of Rome. Her first book, *The Montessori Method,* was published in 1912. It described experiments made with little children (ages 3 to 6) in the slum quarters of Rome, in so-called "Children's Houses" (*Case dei Bambini*) or rooms set apart in the courtyards of large tenement buildings as part of a reformed dwelling scheme inaugurated by E. Talamo. Dr. Montessori began her studies of educational problems with defective children. Working on lines first laid down by the French physician, Dr. Séguin, she achieved startling results; idiot children under her tutelage passing the State examination in reading and writing for normal children. She then turned her attention to the education of normal children, since it seemed to her that if backward children by educational means could be led to overtake normal children, it should be possible to produce still more startling results with the normal child. A year in the *Casa dei Bambini* justified her hopes. These schools became world-famous, and were visited from all parts.

Before starting work with normal children Dr. Montessori had examined the educational systems of Europe, and to her it seemed astonishing to find everywhere the children reduced to immobility in the class-rooms "like rows," as she said, "of butterflies transfixed with a pin." Such children, she declared, were not "disciplined but annihilated." In her schools the contrary practice was established. Freedom of movement was the rule, provided it did not transgress the borders of good manners, social order and harmony. She proved that on these lines an astonishingly perfect discipline can be built up, even with quite tiny children. The children worked happily together moving independently to and fro, as in a well-ordered community of adults. Such "free discipline," as it is now called, is beginning to be everywhere adopted in schools.

But another, and, if anything, more profound aspect of her work lies in the "educational apparatus" or "didactic material" specially provided. Building on the work of Séguin, Dr. Montessori discovered that it is possible to devise objects of a very simple and yet exact type which provoked in the young child a profound reaction of interest and attention, such as she, in common with previous psychologists, had never believed possible. At first, she tells us, she could hardly believe her eyes. Little children of between three and four would repeat an exercise with an air of concentration and indifference to surrounding distractions, that we have been hitherto accustomed to associate only with men of genius. Such a period of "work" might continue from a quarter of an hour to an hour, and then the child would seek other work, upon which he would concentrate in a similar way. Moreover, the child did not seem tired, as after an enforced effort, but rather refreshed and tranquillized. Indeed, disorderly children—those of a type likely at any moment to lapse into some form of indiscipline—invariably acquired inward stability once they had entered upon this form of spontaneous work. The teacher in the second and subsequent years of the class's formation had very little to do in the direction of maintaining order.

This set her the more free for a delicate and exacting portion of her work, the teaching of the children by giving them little, mainly individual, lessons at appropriate moments, and in introducing them to new portions of the material as required. Wherever movements are involved, the teacher shows in *the first instance the precise and best way* of performing the movement. This prevents the formation of an imperfect habit and has universal importance, as all teachers of music or games are aware. Thus children, at an early age, can scrub a table and consider it part of the fun not to spill a drop of water; they can wash-up after meals, wring out and iron their little dusters, etc. Little waiters carry round the dishes at meals, and it is no uncommon sight to see a child of three in sole charge of the soup tureen.

Children in the *Casa dei Bambini* learn to write, read, count and work simple sums before the age of six. Since the publication of her first book, Dr. Montessori has been at work on material for older children, and has now perfected means by which they can individually study grammar, geometry, arithmetical operations with large numbers, fractions and so on. Music and art work is also fully developed. An account of this is given in her book, *The Advanced Montessori Method,* dealing with the ages six to ten.

Dr. Montessori, who is a Roman Catholic, has also evolved methods of religious instruction for use in connection with her system. (*See* also NURSERY SCHOOLS, KINDERGARTEN.)

MONTEVERDI or **MONTEVERDE, CLAUDIO** (1567–1643), Italian composer, was born at Cremona in May 1567. His attention was early directed to the infant art of instrumental music, and the duke of Mantua gave him his first appointment as viola player, under Ingegneri, a good polyphonic church composer (his *Responsoria* were long ascribed to Palestrina), from whom he learnt composition. In 1602 he succeeded Ingegneri as maestro di capella to the duke; and in 1607 he made a decisive impression with his first opera, *Arianna,* in which was revealed the emotional and dramatic value of a new treatment of discords which, in his unaccompanied madrigals, had merely seemed to indicate the downfall of pure polyphony. This work at once elevated the lyric drama, feebly essayed by Peri's *Euridice* in 1600, to a level of art which musicians were henceforth compelled to take seriously. Still more successful was *Orfeo,* composed in 1608. In *Il Combattimento di Tancredi e Clorinda,* the description of a duel was accompanied by quickly repeated chords on the strings (not, as is usually alleged, a tremolo) which so scandalized the players that all Monteverdi's tact and determination was needed to induce them to play it. He had already written *pizzicato* passages (with the direction "here you put down the bow and pull the string with the finger"). The Amati family

of violin makers at Cremona had begun their work in the nick of time for Monteverdi's purposes; for it is doubtful whether even his resourcefulness could have so effectively revolutionized music if the feeble flat-backed viols had been his only instruments with string and bow. In 1613 Monteverdi became maestro di capella at St. Mark's, Venice, where he composed much sacred music, now lost. In 1632 he became a priest. He produced four more operas before his death, on Nov. 29, 1643.

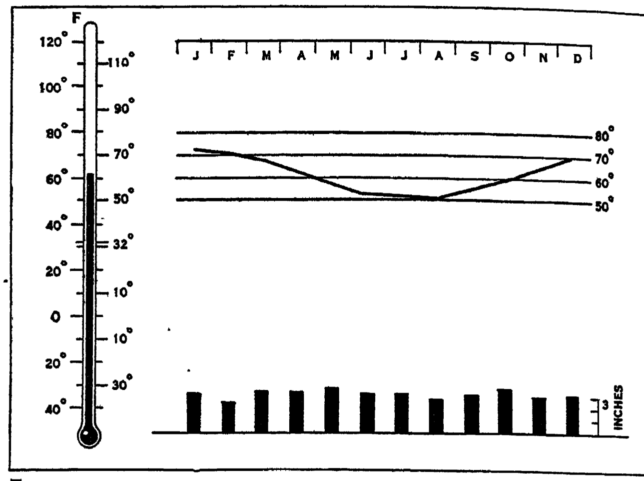
Monteverdi's conspicuous position in musical history gives rise to many misunderstandings as to his artistic merits. In the history of the fine arts it is much easier to write vividly about tendencies than about results. Mature works of art are things in themselves, and demand to be so understood without regard to what comes after them. Resisting interpretation in other terms than their own, they are not easy to describe. But tendencies are always interesting. Accordingly the student finds that the historian whom Palestrina and Bach paralyse into hagiology writes as if Monteverdi were the Wagner of a 17th century more glorious than the 19th. And this is difficult to reconcile with the fact that if all the music of the 17th century were destroyed, not a single concert-goer would miss it. A glance at the score of one of Monteverdi's operas, or at the quotations given in musical histories, produces a disillusion unnecessarily great; we seem to be plunged into a more archaic period than that of the earliest efforts at polyphony. A modern stage performance restores the illusion. But an illusion it remains; for Monteverdi lived in the hey-day of baroque stage-production, and on anything like a faithful reproduction of his stage, it matters little whether we hear his finest rhetoric, or poor Peri's efforts, or the experimental psalmody of modern amateurs who know nothing about music.

Meanwhile good service has been done in the rehabilitation of Monteverdi as an artist, by Malipiero's complete score of all his extant madrigals. In his preface, Malipiero holds up, as a warning to modern critics, the censure of Artusi, and points out that Artusi recanted afterwards. The warning is misplaced. Monteverdi was no Keats, neither was Artusi a *Quarterly* reviewer. Artusi saw, and said, that the treatment of discords in Monteverdi's madrigals was subversive of pure polyphony. This was true, and Monteverdi's reply was that the rules of Zacconi's *Practica di Musica,* which were in conflict with the details (*alcune minime particelli*) of modern music, did not concern him, since he was not writing by accident, but was establishing a *Seconda Pratica* which, at the instigation of Artusi's attack (*Degli Imperfezioni,* etc.) he would call *La Perfettione della Musica Moderna.* In these six books of extant madrigals, it is fascinating to trace the conflicting elements: the decadence of an old style; the too facile exploitation of new formulas; and, now and again, the achievement of something powerful and mature, which, if introduced into a madrigal concert, would make it impossible to continue the programme with orthodox madrigals.

(D. F. T.)

MONTEVIDEO, capital and chief port of Uruguay, and capital of the department of Montevideo, on the northern shore of the Río de la Plata estuary, 120 m. E.S.E. of Buenos Aires, in lat. 34° 54′ 33″ S., long. 56° 12′ 18″ W. Pop. (1927) 418,000. The old section of the city occupies a low, rocky headland that projects westward between the estuary and an almost circular bay which forms the harbour; it was once enclosed with walls and defended by small forts, all of which have been removed. The new sections of the city extend eastward over a beautiful tract of rolling country, and northward around the eastern shore of the bay. The site of the old city resembles a whale's back in shape; it slopes gently to the western extremity of the city and its union with the newer section, on the line of the old ramparts, known as Calle de la Ciudadela. The streets are well paved and have sufficient slope at all points to give easy surface and underground drainage: Montevideo has the reputation of being one of the cleanest cities of the world. The rainfall is ample (about 44 in. a year), and the prevailing winds help to clean the streets. The mean annual temperature is about 62° F. An abundant water-supply is brought from the Santa Lucía river, 32 m. distant, with a receiving reservoir at Piedras, 100 ft. above the level of the Plaza de la Independencia. The older parts of the city are largely devoted to commercial, shipping and financial interests. The Government edifices, large retail shops and most of the fine urban residences are in the *ciudad nueva* (New City). Numerous bus and electric tramway lines extend to suburbs and to the bathing resorts of Ramírez, Maldonado and Pocitos and the Buceo cemeteries on the eastern coast.

Plazas and Buildings.—One of the finest boulevards in South America is the Calle 18 de Julio, extending eastward from the Plaza de la Independencia to the suburbs. There are numerous plazas within the urban limits: Zabala or Rincón, Constitución or Matriz, Independencia, Libertad or Cagancha, Treinta y Tres, Flores and Frutos, and several suburban parks, the Paseo del Prado and Parque Urbano being among the most popular. The Plaza de la Independencia stands at the junction of the old and new towns and is the centre of the city's political and social life. This square is distinguished for a uniform and nearly completed line of colonnades in front of the buildings surrounding it. The Paseo del Prado, which ranks high among the public gardens of South America, is beautifully situated beyond the suburb of Paso Molino, 3 m. from the city. The Paseo was originally the *quinta* (villa) of a German of cultivated tastes named Joseph Buschenthal, who spent a fortune in its adornment. The Parque Urbano, at the Playa Ramírez bathing resort, is a modern creation. The buildings of Montevideo are chiefly of brick and broken stone, covered outside with plaster and stucco, of one to three storeys, with flat roofs, usually surmounted by a square tower, or *mirador*. The roofs, or *azoteas,* are largely used for domestic purposes, or roof gardens. The city contains a large number of handsome edifices, both public and private, among which are the Bolsa, Government House, municipal hall, cathedral, Cabildo, Hospital de Caridad, insane asylum, Italian hospital, Athenaeum, the Club Uruguayo and theatres. The Bolsa (exchange), custom-house, cathedral and Cabildo are in the old town; the Bolsa is a copy of the Bordeaux exchange. The cathedral faces on the Plaza pavement, and these, with a large dome behind, rise far above de la Constitución. Its two square towers stand 133 ft. above the the surrounding buildings and make a conspicuous landmark. The church was consecrated in 1804, and in 1869 was raised to the dignity of a cathedral. Montevideo is now the seat of a small archiepiscopal see with only two suffragan dioceses. Directly across the plaza is the old Cabildo, a plain, heavy-looking two-storeyed edifice of the colonial period, the seat of municipal administration during Spanish rule, but now occupied by the two chambers of the Uruguayan Congress and by the higher police authorities of the city.



TEMPERATURE AND PRECIPITATION IN MONTEVIDEO. THE MERCURY STANDS AT THE NORMAL ANNUAL MEAN TEMPERATURE, THE CURVE SHOWS THE NORMAL MONTHLY MEAN TEMPERATURE THROUGH THE YEAR, AND THE COLUMNS BELOW INDICATE NORMAL MONTHLY PRECIPITATION

Charities and Schools.—The people of Montevideo maintain more than 40 charitable associations, including the Caridad (charity) hospital on Calle 25 de Mayo, and the insane asylum

in the suburb of La Union, both built and largely supported from the proceeds of frequent lottery drawings. They also maintain a beggars' asylum and a foundlings' asylum. The national museum (founded in 1830) and public library (founded 1833) are in one wing of the Solis theatre. There are a British hospital (founded 1857, the present edifice dating from 1867) chiefly for the use of sailors, an Anglican church in Calle Santa Teresa dating from 1847, and a handsome Italian hospital of modern construction. The University of Montevideo has faculties of law, medicine, letters, mathematics, engineering and other groups of studies, including agriculture and veterinary science. The Government maintains normal schools, a school of arts and trades (*artes y oficios*) and a military school.

Commerce.—The harbour of Montevideo consists of a shallow bay, circular in shape, opening to the south-east, and about 2½ m. from shore to shore, and an outer roadstead exposed to the violent winds of this latitude, where the larger ocean-going steamers were compelled to anchor before the construction of the present port works. In 1899 the Uruguayan Government entered into a contract for the dredging of the bay, the construction of two long breakwaters, the dredging of a channel to deep water, and the construction of a great basin and docks in front of the city. Surtaxes were imposed on imports and exports to meet the expenditure, and work was begun in 1901. The entrance channel, with a minimum depth of 24½ ft., permits the admission of large steamers. Another important improvement, for which a concession was given to an English syndicate, is the extension embankment and new shore line on the south side of the city. There are three large dry-docks connected with the port, known as the Mauá (275 ft. long, inside) and the Gounouilhou (300 ft.) on the east side of the bay, and Jackson and Cibils (450 ft.) on the west side at the foot of the Cerro. Four railways terminate at Montevideo, one of them (the Central Uruguay) extending to the Brazilian frontier. Many lines of ocean-going steamers make regular calls at the port and several lines of river steamers operate to Buenos Aires and the ports of the Paraná, Paraguay and Uruguay rivers. The exports consist chiefly of live stock, jerked beef, hides, wool and other animal products, wheat, flour, corn, linseed, barley, hay, tobacco, sealskins, fruit, vegetables and some minor products. Manufactures exist only to a limited extent and chiefly for domestic consumption.

Suburbs.—The suburbs of Montevideo include the fashionable bathing resorts of Playa Ramirez and Pocitos on the coast east of the city, the inland suburbs of Paso Molino and La Unión and the industrial town of Cerro, across the bay. Maldonado, east of the capital, is another popular resort. The Flores island quarantine station is 12 m. east of the city. The station was formerly on Rat island (within the bay), which is now used as a public deposit for inflammables. The chief point of natural interest is the conical hill known as the Cerro, or "mount," from which the city takes its name, on which stands an old Spanish fort from which rises a tower used as a radio station. The hill's elevation is 486 ft. and a lighthouse also rises from within the fort, carrying a revolving light visible 25 m. at sea.

History.—Montevideo was founded in 1726 through the efforts of Don Mauricio Zabala, governor of Buenos Aires, who wished to check the advance of the Portuguese on this side of the La Plata. A small military post had existed there since 1717, but efforts to create a town had been fruitless until Zabala offered to make *hidalgos* of the first settlers and to give them cattle and sheep. The first families to accept this offer came from the Canary islands in 1726 under the direction of Don Francisco Alzeibar; they were followed by others from Andalusia and some of the Spanish-American settlements. Its growth at first was slow, but on the abolition of the Cádiz monopoly in 1778 it became a free port and its trade increased so rapidly that it soon became one of the chief commercial centres of South America. The city was captured in 1807 by a British expedition under Sir Samuel Auchmuty, but was abandoned when the expedition against Buenos Aires under Gen. Whitelocke was defeated. In 1808 the governor of Montevideo established an independent junta, but after the Buenos Aires declaration of independence in 1810 the Spanish forces were concentrated in Montevideo and held it until expelled in 1814 by the Argentine land and sea forces under Gen. Alvear and Admiral Brown. The dissensions following the expulsion of the Spanish and the rivalries of Argentina and Brazil over the possession of Uruguay, then commonly termed the "Banda Oriental," greatly reduced the population of the city and partially destroyed its trade. It was made the capital of the republic in 1828 and had partially recovered its population and trade when the disastrous struggle with Rosas, dictator of Buenos Aires, broke out and the city was subjected to a nine years' siege (1843–52), the investment being conducted by Gen. Oribe, and the defence by General Paz. In 1864–1865 Brazil intervened in the affairs of the republic, blockaded the port, and reinstated ex-president Flores. The war with Paraguay that followed, which lasted until 1870, made Montevideo the base of supplies for the Brazilian army and navy and added largely to its trade and wealth. In addition to the reckless speculation of this period, there were continued political dissensions, repeated dictatorships and financial mismanagement on the part of the Government. Not the least of these burdens were the personal and irregular drafts of some of the executives upon the treasury and revenue officers, particularly the custom-house of this port, upon which the republic depended for the major part of its revenue. The commercial and financial collapse that followed lasted through the greater part of the last three decades of the century; but settled government and improved finances subsequently contributed to a slow but steady recovery in the trade and industrial activities of the city.

MONTEVIDEO, a city of south-western Minnesota, U.S.A., on the Minnesota river, 40 m. from the South Dakota State line; the county seat of Chippewa county. It is on Federal highway 212 and the main line of the Chicago, Milwaukee, St. Paul and Pacific Railroad. Pop. (1920) 4,419; in 1930, 4,319. It is in a rich farming, dairying, and stock-raising region, and has large grain elevators and several manufacturing industries using the products of the surrounding country.

MONTEZUMA II. (1466–1520), Aztec emperor of Mexico, was born in Mexico in 1466. In 1502, upon the death of his uncle, the emperor Ahuitzoll, he was elected his successor. Protracted wars waged against the republic of Tlaxcala, against Guatemala and against the rebellious province of Tehuantepec, as well as expeditions as far as Honduras and Nicaragua, greatly enlarged his empire. In 1518, word was brought to him of the landing of white men (Grijalva and his band) on the Mexican coast and he ordered the shores to be guarded because of the Aztec tradition that shortly before the break-up of the empire the first chief of the dynasty of Quetzalcoatl would appear out of the east. When Cortes and his men arrived the following year they were met by embassies from Montezuma with gifts of propitiation. Cortes marched toward the capital and soon made the emperor a virtual prisoner and used him to aid his designs for conquest. In June 1520, when the Spaniards were attacked by the natives of Mexico City, Montezuma appeared upon the palace roof to order his people to lay down their arms, but he was in turn attacked by them and so dangerously wounded that he died three days later. The people in their anger against him refused him the elaborate funeral ceremonies granted to all previous emperors.

MONTFAUCON, BERNARD DE (1655–1741), French scholar and critic, was born at the Château of Soulage, in France, on Jan. 13, 1655. He entered the army in 1672 and served for two years under Turenne. In 1675 he became a monk, and lived at various abbeys, going to Italy in 1698, and finally retiring to St.-Germain-des-Près, where he produced most of his works, and died on Dec. 21, 1741. His editions of the Fathers include *Athanasii opera omnia* (1690), still the best edition: *Collectio nova patrum* (1706); *Joannis Chrysostomi opera omnia* (1718–38). In addition, he wrote *Diarium italicum* (1702), an account of the libraries of Italy; and *L'Antiquité expliquée et représentée en figures* (1719), which laid the foundation of archaeology. The last two have been translated into English. His *Palaeographia graeca* (1708), illustrated the whole history of Greek writing.

A list of his works will be found in *Bibliothèque des écrivains de la congrégation de Saint-Maur,* by C. de Lame (1882), and in the

article in the *Nouvelle biographie générale*, which gives an account of their scope and character; *see* also Emmanuel de Broglie, *La Société de l'abboye de St.-Germain-des-Prés au 18e siècle: Bernard de Montfaucon et les bernardins* (2 vols., 1891).

MONTFERRAT, COUNT OF, a title derived from a territory south of the Po and east of Turin, and held by a family who were in the 12th century one of the most considerable in Lombardy. In 1147 a count of Montferrat took part in the second crusade. In 1176 William Longsword, eldest of the five sons of Count William III., came to the kingdom of Jerusalem, on the invitation of Baldwin IV. and the baronage, and married the heiress of the kingdom, Sibylla. He died within a few months; but his wife bore a posthumous son, who became Baldwin V. Count William III., himself (uncle to Philip of France and brother-in-law to Conrad III.) afterwards came to the Holy Land to watch over the interests of his grandson; and he was taken prisoner by Saladin at Hittin in 1187. Shortly after the battle of Hittin Count William's second son, Conrad, appeared. Conrad, following the family tradition, and invited by the emperor Isaac Angelus, had gone to serve at the court of Constantinople. He soon became important; married Isaac's sister, and defeated and killed a usurper; but he was repaid by ingratitude and suspicion, and fled to Palestine in 1187. Putting into Tyre he saved the city from the Mohammedan conquest which followed Saladin's victory at Hittin. He established himself firmly in Tyre (refusing admission to Guy, the king of Jerusalem); and from it he both sent appeals for aid to Europe and despatched reinforcements to the crusaders, who, from 1188 onwards, were engaged in the siege of Acre. His elder brother had been the husband of the heiress Sibylla, who had carried the crown to Guy de Lusignan by her second marriage, and on her death Conrad married her younger sister, Isabella, now the heiress of the kingdom, and claimed the crown (1190). The struggle between Conrad and Guy, supported by Philip Augustus and Richard I. respectively, paralysed the energies of the Christians in 1191. After the departure of Philip, Conrad fomented the opposition of the French to Richard, and even intrigued with Saladin against him. But Richard was finally forced to recognize him as king (April 1192). In the very hour of success, however, Conrad was struck down by the emissaries of the Old Man of the Mountain (the chief of the Assassins).

Another son of Count William III., Boniface of Montferrat, the younger brother of Conrad, was chosen leader of the fourth crusade in 1201, on the death of Theobald of Champagne. In the winter of 1201–02 he visited Philip of Swabia; and there he arranged the diversion of the fourth crusade to Constantinople (*see* CRUSADES). Yet in the course of the crusade he showed himself not unsubmissive to Innocent III., who was entirely opposed to such a diversion. After the capture of Zara, however, he joined the crusaders, and played a great part in all the events which followed till the capture of Constantinople by the Latins in 1204. But Baldwin of Flanders was elected emperor over his head; and his irritation was not wholly allayed by the grant of Macedonia, the north of Thessaly, and Crete (which he afterwards sold to Venice). In 1207 he was killed in battle with the Bulgarians. He left a son Demetrius, who assumed the title of king of Thessalonica, which the father had never borne (*cf.* Luchaire, *Innocent III.: La question d'Orient*, p. 190). In 1222 Demetrius lost his kingdom to Theodore Angelus, and the house of Montferrat its connection with the East.

See Savio, *Studi storici sul marchese Guglielmo III. di Monferrato* (Turin, 1885); Ilgen, *Markgraf Konrad von Montferrat* (1880); and also the works of Cerrato (Turin, 1884) and Desimoni (Genoa, 1886).

MONTFORT, the name of a famous French family long seated at Montfort l'Amauri, near Paris. Of them SIMON IV. DE MONTFORT (*c.* 1160–1218), a son of Simon III. (d. 1181), took part in the crusade against the Albigenses. Twice he went to Palestine as a crusader, and in 1209, answering the call of Pope Innocent III., he joined the host which marched against the enemies of the Church in Languedoc. He became vicomte of Béziers and of Carcassonne, and was soon the leader of the crusaders. He took place after place, defeated Raymond VI., count of Toulouse, at Castelnaudary, and about a year later (September 1213) gained a victory over Raymond's ally, Peter II., king of Aragon, under the walls of Muret. Simon then turned his attention to administering and organizing Languedoc. The pope, somewhat reluctantly, confirmed him in the possession of the greater part of the lands of the count of Toulouse, and after two more years of warfare he was killed whilst besieging the city of Toulouse on June 25, 1218.

The count's eldest son, AMAURI DE MONTFORT (1192–1241), was unable to hold his own, although Philip Augustus sent some troops to his assistance in 1222. He abandoned his interests in the south of France in favour of the new king Louis VIII., and in 1239 he went on crusade to the Holy Land, dying soon afterwards at Otranto. In 1230 Amauri was made constable of France.

See A. Molinier, *Catalogue des actes de Simon et d'Amaury de Montfort* (1873); and C. Douais, *La Soumission de la vicomté de Carcassonne par Simon de Montfort et la croisade contre Raimond VI.* (1884).

MONTFORT, SIMON DE, EARL OF LEICESTER (*c.* 1200–1265), English statesman and soldier, was born in France, the fourth and youngest son of Simon IV. de Montfort (*see* above), the leader of the Albigensian crusade. Simon IV., whose mother was an heiress of the Beaumont family, claimed in her right, and received from King John, the earldom of Leicester (1207), only to lose it again through espousing the French side in the wars between that sovereign and Philip Augustus.

The young Simon, of whose youth nothing is recorded, came to England in 1230 and attached himself to Henry III., obtaining with the consent of his sole surviving brother Amauri a re-grant of the family earldom. Simon was for a time unpopular and closely attached to the royal party. He gave, however, an early proof of religious fervour, and of an unbending harshness, by the expulsion of the Jews from his borough of Leicester. In 1238 he married the king's sister Eleanor, the widow of the younger William Marshal. The match was resented by her brother Richard of Cornwall and the baronage on the ground that Eleanor had taken vows of chastity. With some difficulty Earl Richard was pacified; and Montfort obtained the pope's confirmation of the marriage by a personal visit to Rome. In 1239, however, the influence of detractors and a quarrel over some obscure financial transactions in which he appears to have used Henry's name without a formal warrant led to a breach between himself and the king. The earl and his wife went to France; and, though a nominal reconciliation with the king was effected, both departed on crusade with Richard of Cornwall in 1240. Returning in 1241, Simon took part in Henry's disastrous French expedition of 1242, and was readmitted to full favour.

He stood forward in parliament as a mediator between the court party and the opposition, and was keenly interested in Grosseteste's proposals for ecclesiastical reformation. In 1248 he again took the cross, with the idea of following Louis IX. to Egypt, but at the requests of the king and council, he gave up this project to act as governor in the disaffected duchy of Gascony. Bitter complaints were excited by his rigorous suppression of the excesses of the seigneurs and of contending factions in the great communes. Henry yielded to the outcry and instituted a formal inquiry into the earl's administration. Montfort was formally acquitted on the charges of oppression, but his accounts were disputed by the king, and he retired in disgust to France (1252).

The nobles of France offered him the regency of the kingdom, vacant by the death of the Queen-mother Blanche of Castile, but he preferred to make his peace with Henry (1253), in obedience to the exhortations of the dying Grosseteste. He helped the king in dealing with the disaffection of Gascony; but their reconciliation was a hollow one, and in the parliament of 1254 the earl led the opposition in resisting a demand for a subsidy. In 1256–57, when the discontent of all classes was coming to a head, Montfort nominally adhered to the royal cause. He undertook, with Peter of Savoy, the queen's uncle, the task of extricating the king from the pledges which he had given to the pope with reference to the crown of Sicily; and Henry's writs of this date mention the earl in friendly terms. But at the "Mad Parliament" of Oxford

(1258) Montfort with the earl of Gloucester headed the opposition. It is said that he was reluctant to approve the oligarchical constitution created by the Provisions of Oxford, but his name appears in the list of the Fifteen who were to constitute the supreme board of control over the administration. There is better ground for believing that he disliked the narrow class-spirit in which the barons used their victory; and that he would gladly have made a compromise with the moderate royalists. But the king's success in dividing the barons and in fostering a reaction rendered such projects hopeless. In 1261 Henry revoked his assent to the Provisions, and Montfort left the country in despair.

He returned in 1263, at the invitation of the barons, who were now convinced of the king's hostility to all reform; and raised a rebellion with the avowed object of restoring the form of government which the Provisions had ordained. For a few weeks it seemed as though the royalists were at his mercy; but he made the mistake of accepting Henry's offer to abide by the arbitration of Louis IX. of France. At Amiens, in Jan. 1264, the French king decided that the Provisions were unlawful and invalid. Montfort at once resumed the war, and thus exposed himself to accusations of perjury, from which he can only be defended on the hypothesis that he had been led to hope for a genuine compromise. Though merely supported by the towns and a few of the younger barons, he triumphed by superior generalship at Lewes (May 14, 1264), where the king, the Lord Edward, and Richard of Cornwall fell into his hands. Montfort used his victory to set up the government by which his reputation as a statesman stands or falls. The weak point in his scheme was the establishment of a triumvirate (consisting of himself, the young earl of Gloucester and the bishop of Chichester) in which his colleagues were obviously figureheads. This flaw, however, is mitigated by a scheme, which he simultaneously promulgated for establishing a thorough parliamentary control over the executive, not excepting the triumvirs. The parliament which he summoned in 1265 was, it is true, a packed assembly; but it can hardly be supposed that the representation which he granted to the towns (*see* PARLIAMENT and REPRESENTATION) was intended to be a temporary expedient.

The reaction against his government was baronial rather than popular; and the Welsh Marchers particularly resented Montfort's alliance with Llewellyn of North Wales. Little consideration for English interests is shown in the treaty of Pipton which sealed that alliance (June 22, 1265). It was by the forces of the Marchers and the strategy of Edward that Montfort was defeated at Evesham (Aug. 4). For years after his death he was revered by the commons as a martyr, and the government had no little difficulty in reducing the remnants of his baronial supporters. He was undoubtedly harsh, masterful, and ambitious; but no mere adventurer could have won the friendship of such men as Adam Marsh and Grosseteste; their verdict of approval may be the more unhesitatingly admitted since it is not untempered with criticism.

The original authorities are those for the reign of Henry III. The best biographies are those by R. Pauli (trans. C. M. Goodwin, 1876); G. W. Prothero (1877); C. Bémont (1884). *See* also the letters of Adam de Marsh in J. S. Brewer's *Monumenta franciscana*, vol. i. (Rolls series, 1858); H. R. Luard, *Epistolae Roberti Grosseteste* (Rolls series, 1861); F. S. Stevenson, *Grosseteste* (1899); W. H. Blaauw, *The Barons' War* (1871); T. S. Bateman, *Simon de Montfort* (1923); E. F. Jacob, *Studies in the Period of Baronial Reform and Rebellion 1258–67* (1925). (H. W. C. D.; X.)

MONTGAILLARD, JEAN GABRIEL MAURICE ROQUES, COMTE DE (1761–1841), French political agent, was born at Montgaillard, near Villefranche (Haute Garonne), on Nov. 16, 1761. He was educated at the military school of Sorèze, where he attracted the notice of the comte de Provence (afterwards Louis XVIII.). In 1789 he was in Paris as a secret diplomatic agent, and though he emigrated to England after Aug. 10, 1792, he returned six weeks later to Paris, where his security was probably purchased by services to the revolutionary Government. He was again serving the Bourbon princes when he met Francis II. of Austria at Ypres in 1794 and in the same year saw Pitt in London, where he published his *État de la France au mois de mai 1794,* predicting the fall of Robespierre. He was employed by Louis XVIII. to secure Austrian intervention on behalf of Madame Royale (afterwards duchess of Angoulême), still a prisoner in the Temple, and he drew up the proposition made by the prince to Charles Pichegru, the details of which appear in his "Mémoire sur la trahison de Pichegru" (*Moniteur,* April 18, 1804). He is thought to have indicated the possession by the comte d'Antraigues, agent of the princes, of documents compromising Pichegru. In April 1798 he surrendered to Claude Roberjot, the Hamburg minister of the Directory, further papers relating to the matter.

He followed Roberjot to Holland, and there wrote a memorandum urging the immediate return of Bonaparte from Egypt and his assumption of the supreme power. This note reached Alexandria by way of Berlin and Constantinople. But when he ventured to return to Paris he was imprisoned, and on his release he was kept under police supervision. Napoleon, who appreciated his real insight into European politics, attached him to his secret cabinet in spite of his intriguing and mendacious character. The Bourbon restoration made no change in his position; he was maintained as confidential adviser on foreign and home politics, and gave shrewd advice to the new Government. His career ended with the old monarchy, and he died in obscurity at Chaillot on Feb. 8, 1841.

His *Souvenirs,* which must be read with the utmost caution, were edited by Clément de Lacroix (3rd ed., 1895); his *Mémoires diplomatiques* (1805–19) were published by the same editor in 1896. His *État de la France* was translated into English by Edmund Burke. His other writings include *Ma conduite pendant le cours de la révolution française* (London, 1795); *Histoire secrète de Coblentz dans la révolution des français* (London 1795); *De La France et de l'Europe sous le gouvernement de Bonaparte* (Lyons, 1804); *Situation de l'Angleterre en 1811* (1811); *De la restauration de la monarchie des Bourbons et du retour à l'ordre* (1814); and *Histoire de France depuis 1825 jusqu'à 1830* (1839).

MONTGOMERIE, ALEXANDER (*c.* 1550–*c.* 1610), Scottish poet, son of Hugh Montgomerie of Hessilhead, Ayrshire, spent some part of his youth in Argyleshire and afterwards lived for a time at Compston Castle, in Galloway. He was in the service of the regent Morton; thereafter, on the regent's demission of office in 1578, in that of King James VI. In 1583 the grant by the Crown of a pension of 500 marks was confirmed; three years later he set out on a tour through France, Flanders and other countries. He appears to have been imprisoned abroad, and to have lost favour at the Scottish court, and (for a time) his pension. We have no record of his closing years.

Montgomerie's chief poem is the *Cherry and the Slae,* first printed in 1597 (two impressions). It was frequently reprinted in the 17th and 18th centuries, and appeared twice in Latin guise in 1631, in Dempster's *Cerasum et sylvestre prunum, opus poematicum.* It is included in the collected edition of Montgomerie's Poems, by David Irving (1821), and by James Cranstoun, for the Scottish Text Society (1887). A better text, from a ms. in the Laing collection in the University of Edinburgh, was prepared (1907) for the Scottish Text Society by Mr. George Stevenson. The poem, written in the complicated alliterative fourteen-lined stanza, is a confused allegory—the confusion being due to the fact that sections of the poem were written at different times—on Youth's choice between a richly laden cherry-tree on a high crag and a sloe "bush" at his feet. His other poems are: *The Flyting betwixt Montgomery and Polwart* (1629; 1st ed., 1621); a series of 70 sonnets; a large number of miscellaneous poems, amatory and devotional; and *The Mindes Melodie, Contayning certayne Psalmes of the Kinglie Prophete Dayvid, applyed to a new pleasant tune* (Edinburgh, 1605).

MONTGOMERY, GABRIEL, SEIGNEUR DE LORGES, COMTE DE (*c.* 1530–1574), French soldier, became a lieutenant in the king of France's Scottish guards, of which his father was captain. Having inadvertently caused the death of King Henry II. in a tournament (June 30, 1559) he was disgraced and retired to his estates in Normandy. He espoused the cause of the Reformers. In 1562 he allied himself with the prince of Condé, took Bourges, and defended Rouen from September to October 1562 against the royal army. In the third War of Religion he occupied Béarn and Bigorre (1569). Escaping from the massacre of St. Bartholomew, he went to England and returned

with a fleet for the relief of La Rochelle (1573), but soon had to withdraw to Cornwall. Returning to Normandy in 1574, he defended Domfront, which was being besieged by Marshal de Matignon, but was forced to capitulate on May 25. He was sentenced to death and beheaded in Paris on June 26, 1574.

See L. Marlet, *Le Comte de Montgomery* (Paris, 1890).

MONTGOMERY, JAMES (1771–1854), British poet and journalist, son of a Moravian minister, was born on Nov. 4, 1771, at Irvine in Ayrshire, Scotland. Part of his boyhood was spent in Ireland, but he received his education in Yorkshire, at the Moravian school of Fulneck near Leeds. He edited the *Sheffield Iris* for more than 30 years. As a journalist he advocated parliamentary reform, and was twice imprisoned (in 1795 and 1796). His *Wanderer of Switzerland* (1806), describing the French occupation, attracted the attention of Lord Byron, who declared, in a footnote to *English Bards and Scotch Reviewers,* that the book was worth a thousand "Lyrical Ballads." Montgomery wrote several volumes of verse, humanitarian and religious in sentiment. In *Pelican Island,* his last and best work as a poet, he evidently took Shelley as his model. His reputation now rests chiefly on his hymns, about 100 of which are still in current use. In 1835 Peel gave him a small pension. He died at Sheffield on April 30, 1854.

His poems were collected and edited by himself in 1841. The voluminous *Memoirs,* published in seven volumes (1856–58) by J. Holland and J. Everett, contain information on English provincial politics.

MONTGOMERY, RICHARD (1736–1775), American soldier, was born in Co. Dublin, Ireland, in 1736. Educated at St. Andrew's and at Trinity college, Dublin, he entered the British army in 1756, becoming captain six years later. He saw war service at Louisbourg in 1757 and in the Lake Champlain expedition of 1759, and as adjutant of his regiment he shared in the final threefold advance upon Montreal. Later he was present at Martinique and Havana. In 1772 he left the army, settled in New York, and married a daughter of Robert R. Livingston. Three years later he was a delegate to the first provincial congress of New York, and became brigadier-general in the Continental army. He was sent with Schuyler on the Canadian expedition, and, on Schuyler falling ill, the command devolved upon him. Hampered by the inclemency of the season and the gross indiscipline of the troops, he went forward, gaining a few minor successes and met Benedict Arnold's contingent at Point aux Trembles. They pushed on to Quebec barely 800 strong, but an assault was made on Dec. 31, 1775, and almost at the first discharge Montgomery was killed. The body of the American general was honourably interred by the Quebec garrison. Congress caused a memorial to be erected in St. Paul's church, New York, and in 1818 his remains were conveyed thither from Quebec.

MONTGOMERY, ROBERT (1807–1855), English poet, natural son of Robert Gomery, was born at Bath in 1807. He was educated at a private school in Bath, and founded an unsuccessful weekly paper in that city. In 1828 he published *The Omnipresence of the Deity,* which hit popular religious sentiment so exactly that it ran through eight editions in as many months. In 1830 followed *The Puffiad* (a satire), and *Satan.* His name was immortalized by Macaulay's famous onslaught in the *Edinburgh Review* for April 1830. This exposure did not, however, diminish the sale of his poems. *The Omnipresence of the Deity* reached its 28th edition in 1858. In 1830 Montgomery entered Lincoln college, Oxford; he took orders in 1835, and held various preferments. He died at Brighton in 1855.

MONTGOMERY, a town and district of British India, in the Punjab. The town has a station on the North-Western railway about half-way between Lahore and Multan. Pop. (1921), 14,601. It was founded in 1864 on the opening of the railway, and called after Sir Robert Montgomery, then lieutenant-governor. It was then situated in a desolate upland, and though not unhealthy was singularly comfortless until reached by irrigation from the Lower Bari Doab Canal in 1913.

The District of Montgomery lies in the Bari Doab, or tract between the Sutlej and the Ravi, extending also across the latter river. Area, 4,623 sq.m. The district which was formerly a barren wilderness is now, owing to the Lower Bari Doab irrigation, a well cultivated tract. The population in 1921 was 713,786. The principal crops are wheat, pulse, cotton and fodder. Camels are bred for export. The leading manufactures are of cotton and silk, and lacquered woodwork, and there are factories for ginning and pressing cotton.

From time immemorial the Bari Doāb formed the home of a wild race of pastoral tribes. The site of Harappa in this area contains archaeological matter of the highest interest, indicating a very early connection between Indian and Sumerian culture. British influence was first exercised in the district in 1847, when an officer was deputed to effect a summary settlement of the land revenue. Direct British rule was effected on the annexation of the Punjab in 1849. There was a general rising of the wild clans during the Mutiny of 1857, several actions being fought before order was restored.

MONTGOMERY, the capital city of Alabama, U.S.A., and the county seat of Montgomery county; at the head of navigation on the Alabama river, S.E. of the centre of the State. It is on Federal highways 31, 231 and 80; and is served by the Atlantic Coast Line, the Central of Georgia, the Louisville and Nashville, the Mobile and Ohio, the Seaboard Air Line and the Western of Alabama railways. Pop. (1920) 43,464 (46% negroes) and 66,079 in 1930 (Federal census). The city occupies an undulating site, around a sharp bend in the river, in the midst of rich farm lands. The capitol stands on an eminence at the head of the main business street, which (tradition says) was reserved for the purpose from 1819, though Montgomery did not become the capital until 1847. The high-domed central portion (erected 1851) of the present building is one of the finest examples of the classical Georgian architecture in America, and its rotunda was decorated in 1928 by Roderick D. MacKenzie with scenes from the history of the State. Here on Jan. 7, 1861, Alabama voted to secede from the Union; on Feb. 4 the Confederate States of America was organized by delegates from six States; and on the steps of the portico Jefferson Davis took his oath of office. The house occupied by Mr. Davis ("the first White House of the Confederacy") has been moved from its original site to grounds south of the capitol and is used as a museum. At the south-eastern edge of the city is the 62 ac. campus of the Woman's College of Alabama (Methodist Episcopal; 1909), and the State Normal school for negroes is located here. Maxwell field, 1·5 m. outside the city, is a station of the Army Air Corps. The city's assessed valuation of property for 1927 was $37,984,797. It has a commission form of government. Its morning paper, the *Advertiser,* has been published continuously since 1828.

Montgomery is an important concentration point and a market for cotton, mules, yellow pine and hardwood lumber; has a large jobbing and wholesale business; and is one of the principal centres in the country for the manufacture of commercial fertilizer. It has large railroad shops, and various other manufacturing industries, with an aggregate output in 1925 valued at $16,162,380. The hydro-electric developments on the Coosa and the Tallapoosa rivers are within 40 miles. Debits to individual accounts in the city's banks totalled $287,620,000 in 1926. The State fair is held here annually.

In Sept. 1540, De Soto spent a week at the Indian village of Towassi, within the present limits of Montgomery, to let his horses fatten on the green grass along the Alabama river, and a later village, Econchati, was visited by de Bienville and was a British headquarters in 1778. In 1817 Samuel Dexter of Massachusetts and Gen. John Scott of Georgia laid out towns called New Philadelphia and East Alabama, which (together with a third settlement, Alabama Town) were consolidated in 1819 under the present name, in honour of Gen. Richard Montgomery, and incorporated by the legislature sitting at Cahaba. The town was chartered as a city in 1837, became the State capital in 1847, and was the first capital of the Confederacy (until May, 1861) and the seat of Confederate military factories. On April 12, 1865, it was captured by Federal troops.

MONTGOMERY (Welsh *Drefaldwyn*), a municipal borough and the county town of Montgomeryshire (*q.v.*). Pop.

(1931) 918. It is a quiet market town, with a declining population, but its cattle market remains important and well-known. Had it not been for the attraction, via Welshpool, of the railway from Shrewsbury into Wales, the town, situated as it is at the meeting-place of two valley ways (via Minsterley and via Bishop's Castle) from England, would perhaps have renewed its life, and the question of rail connection with England via Craven Arms may be reopened. It is placed within a mile of the English border, marked here by Offa's Dyke, under a steep wooded cliff which dominates the lowland area where the river Camlad, flowing from England, joins the Severn. Above the town rises the Castle hill with the ruins of a castle, built, in the first instance, by the Norman Roger de Montgomery, from whose ancestral home the fortress took its name. The Welsh name (Baldwyn's Town) comes from that of the builder of the second castle on the site, Baldwyn de Boller, who held it for Henry I. The Crown gave it, in the 15th century, to the Herberts of Chirbury, one of whom, in 1644 surrendered it to the Parliamentarians, who dismantled it. The beautiful old parish church is dedicated to St. Nicholas.

MONTGOMERYSHIRE (Welsh *Sir Drefaldwyn*), a county of Wales, bounded N. by Denbigh, N.E. and E. by Shropshire, S. by Radnor and Cardigan, W. and N.W. by Merioneth. Its length from S.E. to N.W. is about 30 m., and from N.E. to S.W. about 35 m. The county occupies, in general, the valleys of the upper Severn and its many tributaries, collected from the plateau under the Berwyn mts. on the north-west by the river Severn, which flows to the north-north-east; while the valley of the Dovey opens on to Cardigan bay in the west. The dissected plateau of the north-west has heights varying from 1,500 ft. towards the Berwyns (which rise to 2,700 ft.) to 500 ft. in the east. In the south-west the county meets Cardigan on the Plynlymon moors (over 2,000 ft.) while Rhyd Hywel and the Kerry hills (1,700 ft.) form the boundary on the south. On the Shropshire border most of the conspicuous Breidden hills (1,324 ft.) are included, and also Corndon hill (1,684 ft.), which forms a part of the group of hill ridges of ancient rock including the Stiper stones and Long Mynd in Shropshire.

Along the eastern border the structure lines run north-east–south-west, and have resulted in three lowland ways from England, those of Llanymynech in the north, Middletown south of the Breidden hills, and of Minsterley between Long Mountain and Stiper stones. The fourth historic way is that of Bishop's castle, formed by a transverse valley (north-west–south-east) cutting across the "grain" of the country. In the Breiddens and in Corndon are large laccoliths of dolerite, quarried for road metal. On the edge of the forest of Clun the Old Red Sandstone crosses the Montgomeryshire border. For the rest the rocks are almost exclusively Ordovician and Silurian, with numerous metalliferous veins (lead, silver and zinc) which have been worked from time to time. The Silurian rocks are mainly Wenlock beds with a fringe of Llandovery rocks, and they lie in the form of a complex syncline down the centre of the county from Lake Vyrnwy to Llanidloes and Newtown.

The moorland plateau of north Montgomeryshire, from the Berwyn range to the Severn valley, is seamed by the deep tributary valleys of Tanat, Vyrnwy, Banwy and Rhiw. The line of the old Cambrian railway (now G.W.R.) from Welshpool, leaving the Severn at Caersws and thence following the Carno river through a low watershed to the upper Dovey valley, separates these moorlands from those of Plynlymon and Rhyd Hywel. The upper Wye valley is included in this corner of the county. The only important Welsh right bank tributary of the Severn, the Camlad, rises in England and joins the main river below Montgomery. Beyond Welshpool the valley opens out and at the Vyrnwy confluence the Severn leaves the county, its broad flood plain merging into the lowlands of north Shropshire.

Glacial deposits cover a large proportion of the county. For the most part the shales and grits of the hilly regions are grass grown, but frequently boggy in the flatter moorland areas. The low entrances from England, the Severn and Rea valleys, are floored with alluvium and, though fertile, are liable to floods.

History.—From the distribution of prehistoric tumuli and sites in the county we learn that the centres of habitation were the open moorlands of north-west, west and south. Finds of stray bronzes indicate that some use may have been made, as a trade and migration route, of the open hill line from the south Shropshire hills to the gap between the mountain ramparts of Plynlymon and Mawddwy and so to Cardigan bay. From the Early Iron Age Montgomeryshire occupied a more important place in prehistoric Wales, for here the hill-camps (which may, however, be of Romano-British construction) are specially thick. It is probably to the occupiers of these camps that we owe the introduction of Brythonic speech, some forest clearing and perhaps village settlement and the making of hillside tracks. The wedge of invasion thus indicated formed the basis for the geographical distinction of the future Powysland and the shire of Montgomery.

The Romans seem not to have occupied Wales in the sense that they occupied the border from Chester to Caerleon. Their stations in Wales were mainly military, though there were doubtless peaceful relations with the natives. In Montgomeryshire there are Roman camps in the notable lowland basins of the lower Vyrnwy (Clawdd Coch), of Montgomery (Caer Flos) and of Caersws, while there was probably a station at Machynlleth, or at any rate at Pennal, just in Merionethshire. Roads from Chester (Deva) and Viroconium met at Caer Flos (the Forden Gaer, excavated in 1927 and following years) and continued to Caersws (excavated in 1912). The large British camp on the Breidden hills (Craig Breidden) is claimed to be the scene of the defeat of the British leader, Caractacus, in A.D. 51.

The post-Roman centuries saw the coming of the Celtic Saints with their civilizing influence, and the foundation of numerous villages (Llan) dedicated to the local saint. The next landmark of importance was the building of Offa's Dyke (8th century), a long line of demarcation between the dominions of the Welsh princes and those of the invading Saxons (*see* Cyril Fox, "Offa's Dyke: A Field Survey," *Archaeologia Cambrensis,* 1926, etc.). Within the county it stretches from Carreghova to Castlewright, with the exception of three miles under the Breidden hills, where the Severn serves as dividing line. By the time of Domesday the English had crossed Offa's Dyke and established their valley villages in the plains of the Severn as far as the river, but the whole border strip remained a battle-ground for centuries, and, until the time of Elizabeth, probably had little population outside the castle towns and moated farms.

From the Welsh side we learn little until the death of Rhodri Mawr in 877, when out of the united Wales were carved three divisions, with Powys as the central part, including what later became Montgomeryshire. Powys castle (*see* WELSHPOOL) was founded in 1108. The Normans, pushing up the valley ways from England, built an outer and inner line of castles in the Marches. The two ways (*see* above) from Minsterley and Craven arms—the latter "Road of the Castles" past Stokesay and Bishop's castle being thronged with historic memories—meet in the basin of the Camlad, where Caer Flos, the Roman camp, was in a sense revived by the Norman castle at Montgomery (*q.v.*), built by Roger de Montgomery in 1074.

Another civilizing force came with the monasteries and other religious foundations of the middle ages, and under the guidance of the monks and that of the numerous Flemish families introduced in the 14th century Powysland became one of the leading wool-producing and manufacturing regions of Wales. The woollen goods were taken to the markets at Shrewsbury and Ludlow. By Tudor times something like order had been established in the Marches, and trade brought fame to the Welsh woollen fabrics The county of Montgomery, based on fundamental physical, linguistic and historic facts, was formed in 1535. English customs and ideas, *e.g.*, the half-timbered houses, spread up the valleys during the late 16th and succeeding centuries. The style eventually reached the western end of the county at Tyn-o-hir above the Dyfi estuary but did not spread into Cardiganshire. At the same time English speech, used at the markets, spread into the valleys replacing the Celtic tongue.

Trade and Communications.—The late 18th and early 19th

centuries witnessed a great development of means of communication, canals and coach roads within the county and trade increased rapidly. In 1794 the Montgomeryshire Canal act was passed, which provided for the construction of a branch canal from the Ellesmere canal to Welshpool, with a future extension to Newtown. Though the canal is now disused, it has carried a vast amount of agricultural produce and coal, timber, lime and flannel goods. The factory system and the new facilities for communication caused the flannel industry to gravitate to the larger centres *e.g.*, Welshpool, Newtown, Llanidloes and Machynlleth (*q.v.*), but it has since declined in all these places. The Cambrian railway, now G.W.R., crosses the county from Llanymynech to Machynlleth, following the Severn valley to Caersws and crossing the watershed to the Dovey valley at Talerddig. All sections of the railway were completed by 1863. From Buttington a joint G.W. and L.M.S. line follows the Middletown gap south of the Breiddens, to Shrewsbury; while from Moat Lane junction, in the Caersws basin, another line gives communication with central Wales via Llanidloes and Builth. Branch lines of the main railway run from Llynclys (in Shropshire) to Llangynog (Tanat valley), from Llanymynech to Llanfyllin, from Welshpool to Llanfair Caereinion, from Abermule to Kerry, from Caersws to the Van Mine, from Cemmaes Road to Dinas and from Machynlleth to Corris.

Another industry now in decay besides that of flannel manufacture is lead mining, formerly carried on extensively in the Llanidloes district in the south and in the neighbourhood of Llangynog in the north. The Van mines near Llanidloes were worth £1,000,000 in 1870. Attempts are being made to resuscitate some mines, and to get metal from the waste tips which disfigure many of the higher hill slopes. Slate quarrying is carried on at Llangynog and in the Machynlleth district, while hard stone for building and road mending is found in various parts. In general Montgomeryshire is a land of hill pastures, with small holdings having sheep rearing as their main occupation. The Kerry Hill breed of sheep, with characteristics embodying those of the Welsh and the Shropshire breeds, is justly famous. The eastern border and the valleys have much rich agricultural land, wheat and oats being the chief crops. Montgomeryshire is said to be the best wooded of all the Welsh counties, hedgerow timber being specially characteristic. The county was formerly a recognized source of oak timber for the navy. Since 1880 there has been much planting of soft woods on the hill slopes below 1,000 ft., the Kerry hills, reached by the branch railway from Abermule, being thickly timbered before 1914. Since then many acres, in part under Government supervision, are being planted each year.

Population.—The area of the administrative county is 510,110 ac., or 797 sq.m., with a population of 48,462 in 1931 (1901, for comparison, was 54,901). Much Welsh is spoken in the mountain regions of west and north, but the towns and lowlands (except the Dovey and upper Severn valleys) are almost exclusively English in speech. The county returns one member to parliament. Llanfyllin (1,449), Montgomery (918), Llanidloes (2,356), Welshpool (5,637) are municipal boroughs, while the urban districts are: Newtown and Llanllwchaiarn (5,152) and Machynlleth (1,892). The county is in the North Wales and Chester circuit, assizes being held alternately at Newtown and Welshpool. Welshpool borough has a separate commission of the peace, but no separate court of quarter sessions. The ancient county (in Bangor, Hereford and St. Asaph dioceses) has 59 ecclesiastical parishes or districts, with parts of 11 others.

MONTGOMERY WARD AND CO., INC., one of the largest mail-order firms and one of the foremost distributors of retail merchandise in the United States, was founded in 1872, by A. Montgomery Ward, the originator of the mail-order method of selling, and the first to put it into practice. The present company was formed in 1919 under the laws of Illinois to succeed a company which had been incorporated in New York (1913) as successor to an Illinois organization. Montgomery Ward and Co. with headquarters in Chicago, distributes goods, through various branches, all over the United States and also conducts an important export trade. The merchandise, of which almost 40,000 items are listed in the company's catalogue, is delivered to patrons by mail from central warehouses strategically situated. Each of these mail-order plants (nine in number, 1929) operates a retail department store where goods are sold over the counter to local residents at mail-order catalogue prices. The largest plant is in Chicago. Merchandise is bought from markets in practically every country in the world. For the production of many lines of goods, the company operates its own factories.

The mail-order business in general increased rapidly in the six years 1923–28, inclusive; during that time the sales of Montgomery Ward and Co. evidenced a greater growth than in all the preceding period of its existence, the number of customers increasing from 3,500,000 to more than 10,000,000. In 1928 approximately one out of every three families in the United States was served. In 1927 net sales passed the $200,000,000 mark for the first time, and in 1928 reached a total of $232,000,000. In 1926 Montgomery Ward and Co. established experimental display stores in several towns through the United States with the object of showing customers what they might order. These were soon converted into regular retail stores and the company embarked on a chain store programme. During 1928, 250 chain stores were opened in cities of over 5,000 population and plans laid gradually to increase the number to 1,500. In addition the company began the same year the establishment of a chain of retail department stores in the large cities. Sixteen such establishments had been opened by Jan. 1, 1929. (G. B. Ev.)

MONTH, originally the period between the two returns of the new moon, now generally called a *lunar month*. The *anomalistic month* is the mean time taken by the moon in passing from one perigee to the next; the *sidereal month* is the mean time in which the moon makes a circuit among the stars; the *tropical month* is the mean time in which the moon traverses 360° of longitude; the *nodical* or *draconic month* is the mean time taken by the moon in passing from one rising node to the next; the *solar month* is one-twelfth of a tropical year. The lengths of the various months are synodic = 29·53059 days; anomalistic = 27·55460, sidereal = 27·32166, tropical = 27·32156, nodical = 27·21222, solar = 30·43685. (For *calendar months* see CALENDAR.)

MONTHOLON, CHARLES TRISTAN, MARQUIS DE (1782–1853), was born at Paris. Entering the army in 1798, he joined the party of Bonaparte, who trusted him and gave him many important missions. He and his wife accompanied the ex-emperor to St. Helena. To Montholon chiefly, Napoleon dictated the notes on his career. With Gourgaud, who was no less vain and sensitive than himself, there was a standing feud, which would have led to a duel but for the express prohibition of Napoleon. Las Cases left the island in November 1816, and Gourgaud in January 1818; but Montholon stayed on at Longwood to the end of the emperor's life (May, 1821).

In 1840 he acted as "chief of staff" in the absurd "expedition" conducted by Louis Napoleon from London to Boulogne. He was condemned to imprisonment at Ham, but was released in 1847; he then retired to England and published the *Récits de la captivité de Napoléon à Ste Hélène*. In 1849 he sat in the Legislative Assembly. He died on Aug. 21, 1853.

See *Recueil de pièces authentiques sur le captif de Ste Hélène: suivi de lettres de MM . . . le Général Montholon, etc.* (1821); *Mémoires pour servir à l'histoire de France sous Napoléon* (ed. Gourgaud and Montholon, 1823; Eng. ed., 1823; new ed., Paris, 1905); *Récits de la captivité de l'empereur Napoléon à Ste Hélène* (2 vols., 1847). Also the Marquise de Montholon's *Souvenirs de Ste Hélène, 1815–16* (1901). Of Montholon's own writings the only one of note is *De l'Armée française* (1834). For the conversations of Montholon with Basil Jackson in 1828, *see* Lieut.-Colonel Basil Jackson, *Notes and Reminiscences of a Staff Officer* (1903). The *Lettres du comte et de la comtesse de Montholon* were edited by Connard (1906).

MONTH'S MIND, in mediaeval England a service and feast held one month after the death of anyone in his or her memory. Bede speaks of the day as *commemorationis dies*. These "Minding days" were of great antiquity, and were survivals of the Norse *minne* or ceremonial drinking to the dead (*see* HEALTH).

MONTILLA, a town of Spain, in the province of Cordova, 32 m. S. of the city of Cordova, by the Cordova-Bobadilla rail-

way. Pop. (1920), 14,868. The peculiar flavour of the pale dry light wine of Montilla gives its name to the sherry known as Amontillado. Montilla was the birthplace of "The Great Captain," Gonzalo or Gonsalvo of Cordova (1453–1515).

MONTLUC (or MONLUC), **BLAISE DE LASSARAN-MASSENCÔME,** SEIGNEUR DE (*c.* 1502–1577), marshal of France, was born at Condom (Gers). He served first as a private archer and man-at-arms in Italy, with Bayard for his captain, fought all through the wars of Francis I., and was knighted on the field of Cérisoles (1544), to which victory he had brilliantly contributed as adviser to the young duke of Enghien. His chief feat was the famous defence of Siena (1555), which he has told so admirably. When the religious wars broke out in France, Montluc, a staunch royalist, held Guyenne for the king. Henry III. made him in 1574 marshal of France, an honour which he had earned by nearly half a century of service and by numerous wounds. He died at Estillac near Agen in 1577. Montluc's eminence above other soldiers of his day is due to his *Commentaires de Messire Blaise de Montluc* (Bordeaux, 1592), in which he described his fifty years of service (1521–1574).

The *Commentaries* are in the collection of Michaud and Poujoulat, but the standard edition is that of the *Société de l'Histoire de France*, ed. by M. de Ruble (5 vols., 1865–72); a critical edition was published by P. Courteault (1911–14). *See* P. Courteault, *Blaise de Montluc, historien* (1908); J. J. de Broqua, *Le Maréchal de Monluc, sa famille et son temps* (1924).

MONTLUÇON, a town of France, capital of an arrondissement, and the most important industrial centre in the department of Allier. Pop. (1926) 35,274. It is on the Cher, 50 m. S.W. of Moulins by rail. The upper town has steep, narrow, winding streets with several buildings of the 15th and 16th centuries; the lower town, traversed by the Cher, produces glass, chemicals, sewing-machines, and iron and steel, and trades in grain, wood, chemicals, candles, earthenware, marble, glass, pneumatics and artificial silk and woollen goods. The Commentry coal-mines and Néris, a town with thermal springs, are to the south-east. Of the churches, Notre-Dame is of the 15th century and St. Pierre has a 12th century transept. The town-hall, with a library, occupies the site of an old Ursuline convent. There is also the castle rebuilt by Louis II., duke of Bourbon, and taken by Henry IV. during the religious wars. The town, which formed part of the duchy of Bourbon, was taken by the English in 1171, and by Philip Augustus in 1181; the English were beaten under its walls in the 14th century. It has a sub-prefecture, a tribunal of commerce, a chamber of commerce and a board of trade-arbitrators.

MONTMORENCY, the name of a French family, derived from Montmorency (Seine-et-Oise). MATTHIEU I., sire de Montmorency, received in 1138 the post of constable, and died in 1160. His first wife was Aline, the natural daughter of Henry I. of England; his second, Adelaide or Alice of Savoy, widow of Louis VI. and mother of Louis VII., and according to Duchesne, he shared the regency of France with Suger, during the absence of the latter king on the second crusade. MATTHIEU II. was made constable in 1218. During the reign of Louis VIII. he fought chiefly in the south of France (Niort, La Rochelle, Bordeaux). On the accession of Louis IX. he supported the queen-regent Blanche of Castile. He died in 1230. His younger son, Guy, in right of his mother, became head of the house of Montmorency-Laval. ANNE de Montmorency (*q.v.*), so named, it is said, after his godmother Anne of Brittany, was the first to attain the ducal title (1551). His eldest son, FRANÇOIS de Montmorency (1530–1579), was married to Diana, natural daughter of Henry II.; another son, HENRI I. de Montmorency (1534–1614), who became duc de Montmorency on his brother's death in 1579, had been governor of Languedoc since 1563. As a leader of the party called the *Politiques* he took a prominent part in the French wars of religion. In 1593 he was made constable, but Henry IV. showed some anxiety to keep him away from Languedoc, which he ruled like a sovereign prince.

HENRY II. (1595–1632), son of duke Henry I., succeeded to the title in 1614, having previously been made grand admiral. He also was governor of Languedoc. In 1625 he defeated the French Protestant fleet under Soubise, and seized the islands of Ré and Oléron, but the jealousy of Richelieu deprived him of the means of following up these advantages. In 1628–1629 he was allowed to command against the duke of Rohan in Languedoc; in 1630 he defeated the Piedmontese, and captured Prince Doria, at Avigliana, and took Saluzzo. In the same year he was created marshal. In 1632 he joined the party of Gaston, duke of Orleans, and placed himself at the head of the rebel army, which was defeated by Marshal Schomberg at Castelnaudary (Sept. 1, 1632); severely wounded, he fell into the enemy's hands, and abandoned by Gaston, was executed as a traitor at Toulouse on the 30th of October.

MONTMORENCY, ANNE, DUC DE (1493–1567), constable of France, was born at Chantilly, and was brought up with the future King Francis I., whom he followed into Italy in 1515, distinguishing himself especially at Marignano. In 1516 he became governor of Novara; in 1520 he was present at the Field of Cloth of Gold, and afterwards had charge of important negotiations in England. He was made marshal of France in 1522, accompanied Francis into Italy in 1524, and was taken prisoner at Pavia in 1525. Released soon afterwards, he was one of the negotiators of the treaty of Madrid, and in 1530 reconducted the king's sons into France. On the renewal of the war by Charles V.'s invasion of France in 1536, Montmorency compelled the emperor to raise the siege of Marseilles; he afterwards accompanied the king of France into Picardy, and on the termination of the Netherlands campaign marched to the relief of Turin. In 1538, on the ratification of the ten years' truce, he was rewarded with the office of constable, but in 1541 he fell into disgrace, and did not return to public life until the accession of Henry II. in 1547. In 1548 he repressed the insurrections in the south-west, particularly at Bordeaux, with great severity, and in 1549–50 conducted the war in the Boulonnais.

Soon afterwards Montmorency was fighting in the north-east. His attempt to relieve St. Quentin resulted in his defeat and captivity (Aug. 10, 1557), and he did not regain his liberty until the peace of Cateau-Cambrésis in 1559. Supplanted in the interval by the Guises, he was treated with coldness by the new king, Francis II., and compelled to give up his mastership of the royal household—his son, however, being appointed marshal by way of indemnity. On the accession of Charles IX. in 1560 he resumed his offices and dignities, and, uniting with his former enemies, the Guises, played an important part in the Huguenot war of 1562. He fell into the hands of the enemy at Dreux, and was not liberated until the treaty of Amboise (March 19, 1563). In 1567 he again triumphed at St. Denis, but was wounded, and died in Paris, on March 15, 1567.

See F. Decrue, *Anne de Montmorency* (1885), and *Anne, duc de Montmorency* (1889).

MONTMORENCY, a town of northern France in the department of Seine-et-Oise, 2½ m. from the right bank of the Seine and 11 m. N. of Paris by rail. Pop. (1926) 9,591. In the middle ages it was the seat of the family of Montmorency. There is a 13th and 16th century church. The town is a well-known resort of Parisians. To the north-east lies the fine forest of Montmorency. Bleaching and dyeing and the manufacture of lime plaster, bricks and tiles are carried on.

MONTORO, a town of southern Spain, in the province of Cordova, 27 m. E. by N. of the city of Cordova, on the Madrid-Cordova railway. Pop. (1920) 18,140. Montoro was the *Epora* of the Romans. It stands on a rocky peninsula on the south bank of the Guadalquivir, here crossed by a fine bridge of four arches dating from the 16th century. Oil is largely manufactured, and there is considerable trade in timber and agricultural products.

MONTPELIER, the capital city of Vermont, U.S.A., and the county seat of Washington county; 40 m. E.S.E. of Burlington, on the Winooski river, Federal highway 2, and the Central Vermont and the Montpelier and Wells River railways. The population was 7,125 in 1920 and 7,837 in 1930. It is in a region of great beauty, within 20 m. of many lakes and the finest scenery of the Green mts. The State house (first occupied in 1836, almost destroyed by fire in 1857, and subsequently rebuilt and enlarged) is of granite from the famous quarries at Barre, 6 m. S.E. The city has several factories and extensive interests

in the granite industry of the region. The town of Montpelier (named after Montpellier, France) was granted to a company of 60 proprietors in 1780. Settlement began in 1787. In 1805 it was chosen to be the capital of the State, and in 1808 the legislature met here for the first time. It was chartered as a city in 1894.

MONTPELLIER, a town of southern France, capital of the department of Hérault, 31 m. S.W. of Nîmes on the P.L.M. railway and 7 m. from the Mediterranean at Cette. Pop. (1926) 69,440.

Montpellier rose into importance after Charles Martel destroyed Maguelonne in 737. In the 10th century its two portions, Montpellier and Montpelliéret, were held from the bishops of Maguelonne by the family of Guilhem. The Guilhems were succeeded, through marriage, by the house of Aragon, a member of which in 1349 sold his rights to Philip of Valois, Montpelliéret having already in 1292 been ceded to the Crown by the bishops. In 1141 Montpellier acquired a charter afterwards materially extended, and the same century saw the rise of its school of medicine. Several of the ablest teachers of that school were members of an important Jewish colony established in the town. Its school of law dates from 1160, and its university was founded by Pope Nicholas IV. towards the close of the 13th century. Louis IX. granted to Montpellier the right of free trade with the whole of the kingdom. The bishopric of Maguelonne was transferred thither in 1536. In the wars of religion the Protestants captured it in 1567 and it supported the duc de Rohan, only submitting after a long siege (1622). The town-walls, except the royal citadel then just built (1624), were razed (1628). Louis XIII. made Montpellier the seat of one of the *généralités* of Languedoc, and the States of that province met there during the 17th and 18th centuries.

Montpellier, the chief town of Languedoc, stands in a fruitful plain near the right bank of the small river Lez. Features of the town are a fine terrace with views of the Mediterranean, the Pyrenees and the Alps, and the famous Botanical garden, founded in 1593. The 14th century Gothic cathedral, once the church of a Benedictine monastery, suffered severely during the religious wars, and the choir has been rebuilt in 13th century style. The monastery, after being converted into the bishop's palace, has since 1795 been occupied by the famous medical school. A gallery devoted to the portraits of professors since 1239 contains one of Rabelais. Close to the medical school is the Tour des Pins, the chief relic of the mediaeval fortifications. The Musée Fabre contains good collections of paintings and sculptures. Montpellier possesses old houses of the 15th and 16th centuries. The Lez is canalized so as to connect Montpellier with the canal du Midi and with the sea at Palavas. The town has a considerable trade in wine, brandy and fruit. Candles, soap, chemicals, casks, chocolate and liquorice are made. The town is the centre of an *académie* (educational division), of a bishop and a prefect, of courts of appeal and assizes, tribunals of first instance and of commerce, a chamber of commerce, a board of trade arbitrators, and the headquarters of the XVI. army corps.

MONTPENSIER, ANNE MARIE LOUISE D'ORLÉANS, Duchesse de (1627–1693), French memoir-writer, was born at the Louvre on May 29, 1627. Her father was Gaston of Orleans, "Monsieur," the brother of Louis XIII. Her mother was Marie de Bourbon, heiress of the Montpensier family. "La grande mademoiselle" was encouraged to look forward to the throne of France as the result of a marriage with Louis XIV. Ill-luck, or her own wilfulness, frustrated numerous plans for marrying her to persons of exalted station, including Charles II. of England, then prince of Wales. She sympathized with the Frondeurs, and in the new or second Fronde she took nominal command of one of the armies on the princes' side, and in her own person took Orleans by escalade. She had to retreat to Paris, where she practically commanded the Bastille and the adjoining part of the walls. On July 2, 1652, the day of the battle of the Faubourg Saint Antoine, between the Frondeurs under Condé and the royal troops under Turenne, Mademoiselle saved Condé and his beaten troops by giving orders for the gates under her control to be opened and for the cannon of the Bastille to fire on the royalists. She then installed herself in the Hôtel de Ville, and played the part of mediatrix between the opposed parties. She was for some years in disgrace, and resided on her estates. In 1657 she reappeared at court. She was now nearly forty, when a young Gascon gentleman named Puyguilhem, afterwards celebrated as M. de Lauzun (*q.v.*), attracted her attention.

In 1670, Mademoiselle demanded the king's permission to marry Lauzun. Louis at first gave his consent, but other members of the royal family prevailed on him to rescind it. Not long afterwards Lauzun, for another cause (*see* Lauzun) was imprisoned in Pignerol, and it was years before Mademoiselle was able to buy his release from the king by settling no small portion of her estates on Louis's bastards. They were then secretly married. But Lauzun tyrannized over his wife, and they were separated. She lived for some years afterwards, gave herself to religious duties, and finished her *Mémoires,* which extend to within seven years of her death (April 9, 1693). These *Mémoires* (Amsterdam, 1729) are to be found in the collection of Michaud and Poujoulat. Her *Eight Beatitudes* were edited by E. Rodocanachi as *Un Ouvrage de piété inconnu* (1908).

See the series of studies on La Grande Mademoiselle, by "Arvède Barine" (1902, 1905).

MONTREAL, a city of the Dominion of Canada, its leading seat of commerce and principal port of entry, as well as the centre of many of its important industries. It is situated on the south-east side of the island of Montreal, at the confluence of the Ottawa and St. Lawrence rivers, in the county of Hochelaga and province of Quebec. The observatory in the grounds of McGill University, in the city, has been determined to be in 45° 30′ 17″ N. lat., and 73° 34′ 40·05″ W. long. The city holds a fine position at the head of ocean navigation, nearly a thousand miles inland, and at the foot of the great system of rivers, lakes and canals upon which much of the commerce of the interior is carried to the Atlantic seaboard. The ship channel below Montreal, the deepening of which was begun in 1844, now permits the passage of ocean vessels drawing 30 ft. at low water. The Lachine canal, begun in 1821, has been enlarged and deepened from time to time. The depth is now 14 feet. This with the canals above opened the way for the shipping and commerce of the Great Lakes. The first Canadian railway, 1836, ran from Laprairie opposite Montreal to St. Johns, near the international boundary. All these public works owed their existence to the enterprise of Montreal citizens. In 1854 work was commenced upon the Victoria Bridge, completed in 1859, which in 1898 was replaced by the Victoria Jubilee Bridge. At the foot of Lake St. Louis the Canadian Pacific Railway crosses the river on a cantilever bridge. A new road-bridge from Montreal to the south shore was under construction in 1928. Montreal is the headquarters of both the great transportation systems, the Canadian National and Canadian Pacific. The latter has an imposing terminal station on Windsor Square, and the former is planning a very large terminal at the city end of the Mount Royal tunnel. During the season of navigation several lines of well-appointed steamers maintain communication with Liverpool, London, Glasgow and other British and European ports, as well as with the principal ports on the river and gulf of St. Lawrence and the Great Lakes.

Buildings.—Built originally along the water-front, Montreal has in the course of years swept back over a series of terraces—former levels of the river or of a more ancient sea—to the foot of Mount Royal. Held there, it has been forced around the mountain on either side. Mount Royal, from which the city derives its name and so much of its natural beauty, is a mass of trap-rock thrown up through the surrounding limestone strata to a height of 753 ft. above the level of the sea. Under the direction of Frederick Law Olmsted it was converted into a magnificent park. The city is substantially built, grey limestone, quarried from the mountain, predominating in the public and many of the private edifices. To the south of the Place d'Armes stands the parish church of Notre Dame, whose Gothic outlines form one of the striking features of the city. The church was built in 1824 to take the place of an earlier structure dating back to 1672. Beside the church stands the historic seminary of St. Sulpice, one of the few remaining relics of the days of French rule. The head office of the Bank of Mont-

real faces Notre Dame church, and several other of the leading banking institutions of the country have their headquarters in this city. In the Place d'Armes stands a striking figure in bronze erected to the memory of Maisonneuve, the founder of Montreal, and the work of a Canadian sculptor, Louis Philippe Hébert. The Roman Catholic Cathedral of St. James stands upon Dominion Square. It is an almost exact reproduction, reduced to one-half the scale, of St. Peter's at Rome. As this church owes its existence to the energy and enthusiasm of Archbishop Bourget, so Christ Church Cathedral, a fine example of the early English style of architecture, is associated with the name of the first resident Anglican bishop of Montreal, Dr. Francis Fulford.

The mixture of races and creeds, which is so striking a characteristic of Montreal life, has not only endowed the city with many beautiful churches, but also with varieties of philanthropic institutions. Each of the several national societies—St. George's, St. Andrew's, St. Patrick's, and that of the French Canadian patron saint, St. Jean Baptiste, to mention no others—looks after the welfare of its own adherents. Of the several hospitals, the most venerable is the Hôtel Dieu, founded in 1644 by Mme. de Bouillon, a French lady of high rank. The original building, in the early days of Ville Marie, stood without the fort, and was fortified to withstand the attacks of the Iroquois. The site is now covered by a block of warehouses on St. Paul Street. The present buildings, completed in 1861, contain both a hospital and nunnery. The Order of the Grey Nuns, founded by a Canadian lady, Mme. d'Youville, in 1737, cares for hundreds of foundlings and aged and infirm people in the great hospital on Guy Street. The Montreal General hospital was founded in 1819 by public subscriptions, and the Royal Victoria Hospital is a monument to the generosity of Lord Strathcona, Lord Mount Stephen and J. K. L. Ross. Besides these should be mentioned the Notre Dame, the Western and the Children's Memorial hospitals.

Schools.—Montreal provides for the education of its young people through two distinct systems of public schools, one for Roman Catholics, the other for Protestants, each governed by a board of commissioners. The schools are maintained by an annual tax based upon the assessment. Unlike the neighbouring province of Ontario, Quebec makes no provision for a state university. But James McGill (1744–1813) left property valued at the time of his death at £30,000 for the foundation of a college. A royal charter conferring university powers was obtained in 1821. During early years slow progress was made, but with the appointment of Sir William Dawson as principal, in 1855, the institution entered on a career of prosperity. It now embraces ten faculties, arts, applied science, law, medicine, dentistry, pharmacy, agriculture, music, commerce and graduate studies. The finely-equipped Macdonald scientific laboratories, with the Redpath Museum and University Library (275,000 vols. in 1928) form part of a noble group of buildings on the campus in Montreal. Two of these were destroyed by fire in 1907 but have since been rebuilt. The University of Montreal (French) embraces the faculties of arts, dentistry, law, medicine, philosophy, science and theology. The college library (50,000 vols. in 1928) has been enriched by a rare collection of Canadian books and manuscripts, bequeathed by Judge Louis François Georges Baby (1834–1906) of Montreal. The administrative buildings of this University were destroyed by fire in 1919. The University will be housed in new and much larger buildings at the foot of Mount Royal. Of other educational institutions in the city the most important is St. Mary's College, founded in 1848 by the Jesuits, and removed to the present building in 1855. The archives boast a notable collection of early Canadian manuscripts. Historical collections are housed in the Chateau de Ramesay, dating from 1704, and in the McCord Museum, McGill University.

Industries.—Montreal's position as the chief port for the trade of the Dominion, is largely due to the foresight of her great merchants. With the gradual opening up of the means of communication by land and water, and the development of her facilities for handling the exports and imports of the country, the city has increased rapidly in importance. In shipments of grain, as well as in dairy produce, Montreal has far outstripped all her rivals. The total grain receipts in 1928 were 217,316,874 bushels. Montreal now stands fifth among the great ports of the world. The port facilities are thoroughly up-to-date and keep pace with the rapidly growing needs of the city. There were 2,900 factories in the city in 1928 including very large flour mills.

Montreal is governed by a Mayor and 35 aldermen, elected every two years. The city returns 13 members to the Dominion House of Commons and 11 to the Provincial legislature of Quebec. The population of the city, according to the census of 1921, was 618,506; 1931, 818,577. With the suburbs, it was estimated at about 1,000,000, more than half French.

History.—The history of the town is steeped in romance. From that first remarkable scene, so graphically described by Francis Parkman, when, on the 18th of May 1642, Maisonneuve and his little band of religious enthusiasts landed upon the spot where the Montreal Customs House now stands, and planted, in the words of the saintly Dumont, a grain of mustard seed destined to overshadow the land, the history of the town was to be intimately associated with missionary enterprise and such heroism as the world has rarely seen. Montreal began as a religious colony, but its very situation, on the outer confines of civilization and at the door of the Iroquois country, forced it to become a military settlement, a fortified town with a military garrison. Similarly its position, even then an ideal one from a commercial point of view, made it the dominating centre of the fur trade. For a hundred years after its foundation these three influences held sway. Within another hundred years, they had become but atoms in a larger and more varied population. The fur trader of New France, merged after the conquest in the fur trader of the North West Company, remained for a time the one picturesque survival of earlier and more romantic days. Finally he too disappeared.

MONTREUIL, GERBERT DE (*fl.* 13th century), French *trouvère*, author of the *Roman de la violette*. He dedicated his poem (*c.* 1221) to the Countess Marie of Ponthieu, wife of Simon, count of Dammartin and a niece of Philip Augustus. The count Gerard de Nevers of the story stakes his domains on the fidelity of his wife Euriant. Lisiard by calumniating Euriant wins the wager, but in the end the traitor is exposed, and, after many adventures, Euriant is reinstated. Another version of the story is given in the *Roman du comte de Poitiers* and in the tale in the *Decameron* (ii. 9) on which Shakespeare founded *Cymbeline*. Lyrics are inserted in the narrative of the *Roman de la violette*, as they had been in the *Conte de la rose* (1200), known also as *Guillaume de Dole*. A prose version, dating from the early 15th century, provided Wilhelmine de Chézy with the material for her libretto of Weber's opera, *Euryanthe* (1823).

MONTREUIL-SOUS-BOIS, a suburb 7 kilometres east of Notre Dame de Paris in the department of Seine, on the slope and summit of a hill, about 1 m. N. of Vincennes. Pop. (1926) 58,425. Montreuil is specially noted for its extensive peach orchards. The manufactures include paint, oils and varnish, glass and chemical products, and biscuits.

MONTREUIL-SUR-MER, a town of northern France, capital of an arrondissement in the department of Pas-de-Calais, 24 m. S. by E. of Boulogne by rail. Pop. (1926), 2,532. The town with its citadel and ramparts stands on a hill on the bank of the Canche. The church of St. Saulve (12th to 16th centuries), a hospital founded in 1200 and rebuilt in the 19th century, with a fine chapel in the Flamboyant style, and the buildings of the old abbey of Ste. Austreberthe, founded in the 11th century, are interesting. Montreuil is the seat of a sub-prefect. The town owes its origin to a seventh century monastery established by St. Saulve,

bishop of Amiens.

The Château de Beaurepaire was the British G.H.Q. from March, 1916, to April, 1919, in the World War.

MONTREUX, a town in the Canton de Vaud, on the shore east of Lake Geneva, Switzerland, stretching from Clarens to Veytaux. The name includes the communes of the Châtelard and Planches. Pop. (1920) 16,721, mostly French-speaking. There are railway stations at Clarens (15 m. S.E. of Lausanne), Montreux and Territet. From Territet and Montreux a mountain railway runs past Glion and Caux nearly to the top of the Rochers de Naye (6,710 ft.), while from Montreux the Montreux Bernese Oberland railway proceeds via Les Avants through the Col de Jaman by tunnel to Zweisimmen in the Bernese Oberland.

MONTROSE, MARQUESSES AND DUKES OF, David Lindsay, 5th earl of Crawford (*c.* 1440–1495), was created duke of Montrose in 1488 (the first dukedom conferred in Scotland on a person not of royal blood), as a reward for loyalty to James III. during the rebellion of Angus and Prince James. He was deprived of his dukedom by James IV., but it was restored in 1489 for life only.

In 1505, William, 4th Lord Graham, whose wife was the duke's niece, was created earl of Montrose; and this title was held by his descendants till 1644, when James Graham, 5th earl, was created marquess of Montrose and earl of Kincardine. This was the celebrated marquess of Montrose (*q.v.*) of the Civil War, whose son, James (*c.* 1631–69), was known as "the Good Marquess." His grandson, the 4th marquess (d. 1742), was lord high admiral of Scotland in 1705, and lord president of the council in 1706. For his services in promoting the union of Scotland with England, he was created duke of Montrose and marquess of Graham in 1707, becoming in the same year one of the first representative peers of Scotland in the parliament of Great Britain. He was one of the regents of the kingdom on the death of Queen Anne, and was appointed a secretary of state by George I. After suppressing the Jacobite rising in 1715, he was made keeper of the great seal in Scotland. His son David was raised to the peerage of Great Britain with the title of Earl Graham. In 1853 James Lindsay, 24th earl of Crawford, claimed the title of duke of Montrose on the ground that the patent granted to his ancestor David Lindsay in 1488 had not been effectively rescinded, but his petition was dismissed.

MONTROSE, JAMES GRAHAM, MARQUESS OF (1612–1650), became 5th earl of Montrose (*see* above) in 1626. He was educated at St. Andrews, and at 17 married Magdalene Carnegie, daughter of Lord Carnegie (afterwards earl of Southesk). Not long after the outbreak of the Scottish troubles in 1637 he joined the party of resistance to Charles I., signed the Covenant in 1638, and successfully suppressed the opposition to the popular cause which arose in the north around Aberdeen and in the country of the Gordons, though he violated the safe conduct he had promised to Huntley, the leader of the rising, by taking him prisoner to Edinburgh. In 1639, after the signature of the Treaty of Berwick, Montrose was one of the Covenanting leaders who visited Charles. He wished that the clergy should confine themselves to their spiritual duties, and that the king, after being enlightened by open communication with the Scottish nation, should maintain law and order without respect of persons. In the Scottish parliament which met in September, Montrose found himself in opposition to Argyll, was opposed to Argyll's policy of making the three estates equal, thus making the middle classes and the Presbyterians a tool for his own ambition; but he failed to win the support of Charles.

Rather than give way, Charles prepared in 1640 to invade Scotland. Montrose, who was the leader of the royalist party known as the "Plotters," which had arisen within the ranks of the Covenanters, was of necessity driven to play something of a double part. In Aug. 1640 he signed the Bond of Cumbernauld as a protest against the "particular and direct practising of a few," in other words, against the ambition of Argyll. But he defended his country, and in the same month displayed his gallantry in the forcing of the Tyne at Newburn. After the success of the invasion, Montrose was summoned before the Committee of Estates charged with intrigues against Argyll, and in June was imprisoned in Edinburgh castle. After the king's visit to Scotland Montrose shared in the amnesty tacitly accorded to all Charles's partisans.

When the Civil War began in England (*see* GREAT REBELLION) Montrose constantly pressed Charles to allow him to make a diversion in Scotland. Hamilton's impracticable policy of keeping Scotland neutral for long stood in the way of Charles's consent. But in Feb. 1644, when a Scottish army entered England to take part against the king, Montrose, now created a marquess, was appointed lieutenant-general in Scotland. After his unsuccessful attempt in April to invade Scotland with about 1,000 men, disguised as a groom, he made his way in August to the Highlands, where the clans rallied to his summons. He defeated his opponents, with great military skill, at Tippermuir, Aberdeen, Inverlochy, Auldearn, Alford, Kilsyth and Dundee.

In the name of the king, who now appointed him lord-lieutenant and captain-general of Scotland, he summoned a parliament to meet at Glasgow with the object of organizing the Lowlands, on Oct. 20, but the parliament never met, for Charles had been defeated at Naseby on June 14, and Montrose was called to his help. David Leslie, the best of the Scottish generals, was promptly despatched against Montrose whom he discovered on Sept. 12, deserted by his Highlanders and guarded only by a little group of followers, at Philiphaugh. His conduct of the war had alienated the Lowlands. Montrose made his way to the Highlands; but he failed to organize an army. In Sept. 1646 he embarked for Norway. In 1647 he went to Paris, but could get no support from Henrietta Maria. Three years later, burning to revenge the death of the king, he was restored by the exile Charles II. to the now nominal lieutenancy of Scotland. Charles however did not scruple shortly afterwards to disavow his noblest supporter in order to become a king on terms dictated by Argyll and Argyll's adherents. In December 1650 Montrose sailed for the Orkneys with 1,200 men, but 1,000 of them were lost by shipwreck. Reaching Scotland, Montrose tried in vain to raise the clans, and on April 27, was routed at Invercarron. After wandering for some time he was surrendered by Macleod of Assynt, to whose protection, in ignorance of Macleod's political enmity, he had entrusted himself. On May 20, he was sentenced to death and was hanged on the 21st. To the last he protested that he was a real Covenanter and a loyal subject.

The principal authorities for Montrose's career are Wishart's *Res gestae, &c.* (Amsterdam, 1647; abridged trans. in the Stuart series, 1903); Patrick Gordon's *Short Abridgment of Britane's Distemper* (Spalding Club); Gardiner's *Great Civil War;* Napier, *Memorials of Montrose* (1856), containing Montrose's poetry, a selection of which has been edited by R. S. Rait (1901); H. Pryce, *The Great Marquis of Montrose* (1912) and J. Buchan, *The Great Marquis of Montrose* (1913).

MONTROSE, royal burgh, parish and seaport, Forfarshire, Scotland. It is 30¾ m. N.E. of Dundee by the L.N.E. railway and is also connected with the L.M.S. railway company's system by a branch to Dubton. Pop. (1931) 10,196. The town occupies a sandy peninsula, and is bounded by the North sea, the North and South Esk, and by Montrose Basin, a tidal lagoon about 7 m. in circuit. In the mouth of the channel of the South Esk lies the island of Rossie, or Inchbrayock, which is connected with the burgh by means of a suspension bridge and by a drawbridge with the south bank near the large fishing village of Ferryden. The harbour lies between the suspension bridge and the sea, and is provided with a wet dock. The links, with three golf-courses, are very fine, and Montrose is a popular resort. Flax and jute spinning, ship-building, fish-curing, brewing and iron founding are carried on, and there are flour and saw mills and rope-works. The fisheries are of considerable importance and there is a large trade, especially in timber (the chief import) and potatoes (the chief export). Montrose is governed by a provost, bailies and council, and unites with Arbroath, Brechin, Forfar and Inverbervie (the Montrose burghs) in returning one member to parliament, a district group that was represented for many years by John Morley. Montrose received its charter from David I., and was made a royal burgh in 1352. It was destroyed by fire in 1244

Here Edward I. accepted John Baliol's surrender of the kingdom on July 10, 1296. Sir James Douglas sailed from the port in 1330 bound for the Holy Land with the heart of Robert Bruce; and here, too, the Old Pretender embarked in 1716 for France. In 1745 the town threw in its lot with the Hanoverians.

MONT ST. MICHEL (LE), a rocky islet of France, off the coast of the department of La Manche, some 6 m. N. of Pontorson. Pop. (1926) 198. It forms a mass of granite about 3,000 ft. in circumference and 165 ft. in height, rising near the mouth of the Couesnon nearly a mile from the shore, to which it is united by a causeway. In the 8th century an oratory was established here by St. Aubert, bishop of Avranches, in obedience to the commands of an apparition of St. Michael. The place soon became a resort of pilgrims from France, Great Britain, Ireland and Italy. In 966 Richard I., duke of Normandy, founded in place of the oratory a Benedictine monastery. In 1203 the monastery was burnt by Philip Augustus, who afterwards furnished large sums for its restoration (La Merveille). St. Louis made a pilgrimage to Mont St. Michel, and afterwards supplied funds for the fortifications. During the last 30 years of the Hundred Years' War the abbey persistently resisted the English. In 1469 Louis XI. instituted the Order of St. Michel which held its meetings in the salle des chevaliers. During the Wars of Religion, the Huguenots were not able to take the fortress, which opened its gates to Henry IV. in 1595 after his abjuration. In 1622 the Benedictine monks of Mont St. Michel were replaced by monks of the Congregation of St. Maur. In the 18th and 19th centuries until 1863 the abbey was used as a prison for political offenders. The fortress-abbey crowns the more precipitous side of the islet towards the north and west, the sloping portion towards the east and south being occupied by houses. A machicolated and turreted wall surrounds the upper part of the rock. The northern and oldest portion of the ramparts dates from the 13th century; on the south they are pierced by a single 15th century gateway. The single street curves from the gateway up to the abbey, ending in flights of steps leading to the donjon or châtelet. It is bordered by old houses, among which is one built by Bertrand du Guesclin in 1366, and contains a 15th century parish church. Limitations of space led to building of the abbey in three storeys. The floor of the church, partly on the rock, partly upon foundations, and, at the east end, over a crypt, is on a level with the uppermost storey of the monastic buildings. North of and below the apse is the building known as Belle-Chaise. It comprises the châtelet (15th century), a square machicolated entrance structure, the adjoining guard-room (15th century) with the salle des officiers above it, and behind all the Tour Perrine. The Merveille (1203–64) on the north consists of two continuous buildings of three storeys, on the east, one above the other, the hospitium (*aumônerie*), refectory and dormitory, on the west, the cellar, knights' hall (salle des chevaliers) and cloister. Of the fine Gothic apartments the chief are the refectory, divided down the centre by columns and lighted by large embrasured windows, and the superb knights' hall, with a vaulted roof supported on three rows of cylindrical pillars. The 13th century cloister is surrounded by double lines of columns carrying pointed arcades, between which floral designs are carved. The exterior wall of the Merveille, 108 ft. high, is supported by 20 buttresses. The church, high above the other buildings, consists of transepts and four bays of the nave of Romanesque architecture and of a choir (1450–1521) in the Flamboyant Gothic style with a triforium surmounted by windows. In 1776 three of the seven bays of the nave were pulled down, and soon after the incongruous western front was added. The finest part of the exterior is the choir, ornamented with carved pinnacles and balustrading. The central tower terminates in a Gothic spire surmounted by a statue of St. Michael.

BY COURTESY OF G.W.H. BRITT

THE STAIRWAY TO THE ABBEY OF MONT ST. MICHEL

MONTSERRAT, an island in the British West Indies, one of the five presidencies in the colony of the Leeward Islands. Pop., mostly negroes (1921), 12,120. It lies 27 m. S.W. of Antigua, in 16° 45′ N. and 62° 7′ W.; is 11 m. long and 7 m. broad, and has a total area of 32½ sq.m. The island is a serrated range of volcanic peaks rising from the Caribbean Sea, their summits clothed with forests; the still active Soufrière (3,000 ft.) in the south being the highest point. The average temperature is 81° F, the hottest weather being usually tempered by cool sea breezes; the rainfall averages 94 in. per annum. Water is plentiful, and the roads are macadamized and well graded. The principal products are cotton and raw and concentrated lime-juice. The legislature of six crown-nominees sends representatives to the general legislature of the colony. Education is compulsory, and the majority of the schools are managed by the Church of England, to which most of the people belong: the Wesleyans and the Roman Catholics also support schools. Plymouth (pop. 1,532), the chief town, stands on an open roadstead.

The island was discovered by Columbus in 1493, who named it after Monserrado, a mountain in Spain. It was colonized by the British under Sir Thomas Warner in 1632, and was taken by the French in 1664. Restored to the British in 1668, it capitulated to the French in 1782, but was again restored in 1784.

MONTSERRAT, a mountain and monastery in Spain, 30 m. N.W. of Barcelona. The mountain is of grey conglomerate; its main axis trends from west-north-west to east-south-east, and its circumference is about 18 miles. The loftiest point is the Turó de San Jeronimo, also called Mirador and La Miranda (4,070 ft.). On the east the base of the Montserrat is washed by the river Llobregat. The Montserrat consists of jagged pinnacles and spires (*peñascos*) rising abruptly from the base of the mass, which is cloven by ravines, and abounds with precipices. It is the *mons serratus* of the Romans, the *monte serrado* of the Spaniards, and is thus named either in allusion to its jagged appearance, or because it is split, as if sawn by the vast fissure of the Valle Malo. This occurred, say the Spanish legends, at the time of the Crucifixion, when the rocks were rent.

The monastery stands 2,910 ft. high on the edge of the Valle Malo. It owes its existence to an image of the Virgin, said to have been carved by St. Luke and brought to Barcelona by St. Peter in A.D. 30. When the Moors invaded the province in 717 the image was taken to Montserrat and hidden in a cave. In 880 Gondemar, bishop of Vich, was attracted to the cave by sweet sounds and smells, and there found the image, which he determined to take to Manresa. But at a certain spot on the mountain the image refused to proceed farther; there it was consequently deposited, and a chapel was erected to contain it. Round the chapel a nunnery was built, and in 976 this was enlarged and converted into a second Benedictine convent. During the Napoleonic wars (1808–14) it was despoiled of treasures. In 1835, as a result of the Carlist insurrection, the convent was deprived of its estates and the number of monks reduced to about 20. In 1874 the convent, which by a grant of Pope Benedict XIII. had been an independent abbey since 1410, was made subject to the bishops of Barcelona.

Nuestra Señora de Montserrat, Patrona de Cataluña ("Our Lady of Montserrat, Patron Saint of Catalonia"), is one of the most celebrated images in Spain, and her church is visited annually by more than 60,000 pilgrims. The image is small, black, and carved of wood, but possesses magnificent robes and jewels.

MONTT, MANUEL (1809–1880), Chilean statesman, was born on Sept. 5, 1809. He had a distinguished career as a scholar, and was introduced into public life during the presidency (1831–41) of Arieto by Diego Portales. Montt distinguished himself by his courage in the crisis that followed upon Portales' assassination in 1837, though only holding a subordinate post in the government. Afterwards he held several ministerial offices, and during the presidency (1841–51) of Bulnes he became minister of justice and public instruction, and later of the interior. He was elected president in 1851 and again in 1856. Though the Liberals chafed

under his rule, and two revolutions, in 1851 and 1859, took place during his administration, he governed Chile with an energy and wisdom that laid the foundation of her material prosperity. He was ably assisted by his minister of the interior Antonio Varas, and it was from the union of the two statesmen that the well-known ultra-conservative faction, the Montt-Varistas, took their name. His presidency was marked by the establishment of railways, telegraphs, banks, schools and training-colleges. On giving up his post in 1861 he became president of the supreme court of justice, a position which he held up to his death on Sept. 20, 1880. His son Jorje (b. 1846) was president of Chile in 1891–96, and a younger son, Pedro (d. 1910), in 1906–10.

MONTT, PEDRO (1848–1910), Chilean statesman, son of Manuel Montt (*q.v.*), was born in Santiago, Chile, in 1848. He graduated in law at the *Instituto Nacional* in 1870, and four years later entered political life. In 1876 he was elected a member of the chamber of deputies, and in 1885 he became its president. During this period began his powerful influence in the public administration and also in the direction of the National party which Manuel Montt had founded. He voyaged to Europe to study the political institutions of the leading European nations. In 1886 he was appointed minister of justice and public instruction and in 1887 minister of industry and public works. In spite of holding these two cabinet offices in the government of President Balmaceda, Montt figured in the parliamentary opposition to him in 1890, and in 1891 took a very active part in the revolution which put an end to his power. He went to the United States first as agent of the Revolutionary Junta and, after the recognition of the new government, remained as Minister of Chile. In 1901 he was an unsuccessful candidate for the presidency, but in 1906, as the candidate of the National Union ticket and supported by all important elements, he was elected by a large majority. During his term he helped to prevent armed conflict between Chile and Argentina, fostered railway development, worked for sound finances and for sanitation and health projects. He was greatly interested in education and during all his political career was a member of the council of public instruction. His interest in books led him to acquire a private library, the largest in Chile at the time of his death. In 1910, his health failing, he went to Europe to seek treatment and died on Aug. 16, at Bremen, Germany.

MONTUCLA, JEAN ÉTIENNE (1725–1799), French mathematician, was born at Lyons on Sept. 5, 1725. In 1754 he published an anonymous treatise entitled *Histoire des recherches sur la quadrature du cercle,* and in 1758 the first part of his *Histoire des mathématiques,* the first history of mathematics worthy of the name. In 1778 he re-edited Jacques Ozanam's *Récréations mathématiques,* afterwards published in English by Charles Hutton (4 vols., London, 1803). He died on Dec. 18, 1799. His *Histoire* was completed by J. J. Le F. de Lalande, and published at Paris in 1799–1802 (4 vols.).

MONTÚFAR, LORENZO (1823–1898), Guatemalan statesman and author, was born in Guatemala city on March 11, 1823 He studied law at the University of Guatemala and joined with other youthful leaders in publishing the radical periodical *Album Republicano.* Opposition to General Carrera led to forced suspension of the publication. Montúfar went to San José, Costa Rica, where he was named a magistrate of the Supreme Court. After being deprived of this office by force, he took his doctor's degree in law and obtained a professorship at the University of Costa Rica. During the presidency of Juan Ramón Mora he was minister of foreign relations in Costa Rica. He was later named rector of the University of Costa Rica. Afterwards he was forced to fly to San Salvador, which government made him minister to Peru. When Carranza became president of Costa Rica he returned to take the position of minister of foreign relations which he retained also during the presidency of Guardia. As minister he negotiated a number of treaties, notably the treaty delimiting the frontier with Colombia. He was later named envoy extraordinary and minister plenipotentiary of Guatemala to Spain. He was distinguished both as a writer and as a jurist. His most important work is the *Reseña histórica de Centro-America* (7 vol., 1878–81). He also wrote *Apuntamientos sobre economia politica* (1887); *Walker en Centro-America* (1887) and was editor of the advanced periodical *Quincenal Josefino.* In 1891 he was an unsuccessful candidate for the presidency of Guatemala.

The *Discursos del Doctor Lorenzo Montúfar* (R. Montúfar, ed.) was published in 1923.

MONTYON, ANTOINE JEAN BAPTISTE ROBERT AUGET, Baron de (1733–1820), French philanthropist, was born at Paris on Dec. 23, 1733. He rose rapidly in the legal profession, and held several important offices of State. He is best remembered for the numerous prizes which he established, and for the Montyon "prix de Statistique" founded in his honour. Though dealing with economic problems, his books are written mainly from the point of view of the philanthropist, and contain little that is of scientific value. During his life he spent his money freely in the alleviation of suffering, and at his death bequeathed 10,000 francs to each of the Parisian hospitals. His most important works are:—*Recherches et considérations sur la population de France* (1778); *Quelle influence ont les diverses espèces d'impôts sur la moralité, l'activité et l'industrie des peuples* (1808); and *Particularités et observations sur les ministres des finances de France, les plus célèbres de 1690 à 1791* (1812).

See Lacretelle, *Discours sur M. Montyon* in *Recueil de l'académie* (1820–29); Quérard, *La France littéraire,* vol. vi. (1834); F. Labour, *M. de Montyon d'après des documents inédits* (1880); G. Dumoulin, *Montyon* (1884); and L. Guimbaud, *Auget de Montyon* (1909).

MONUMENT, a word whose many meanings are all related to its original root, which signifies a memorial. Thus, in surveying, any natural or artificial object to which the description of a boundary is referred, is known as a monument, and any building or other work of art may be referred to as a monument of a certain style or period. The term is also loosely applied to a gravestone or tomb. More specifically, in architecture, a monument is a structure, erected for the primary purpose of commemorating a person or event. (*See* Religious and Memorial Architecture.)

MONUMENTS, PRESERVATION OF (Lat. *monumentum* or *monimentum;* from *monere,* to advise, bring to mind, remind; the German equivalent is *Denkmal*), literally, that which serves to keep alive the memory of a person, an event, or a period. The word is thus applied to a column, statue or building erected for that particular purpose; to all the various memorials which man throughout the ages has raised over the buried dead, the barrows and cairns of prehistoric times, the representation of the living figure of the dead, brasses, busts, etc., or the varying forms, allegorical or otherwise, taken by the tombstones of the modern cemetery. In a wider sense "monument" is used of all survivals of prehistoric man—dolmens, menhirs, remains of lake dwellings, stone circles and the like, buildings large and small, with cities, castles, palaces, and examples of domestic architecture which have any interest, historic or artistic, as well as movable artistic or archaeological treasures either existing in private or public collections or newly discovered by excavation, etc. In a more restricted sense the word "monument" is also applied to a comprehensive treatise on any particular subject—such as the *Monumenta typographica,* or an historical collection such as the *Monumenta Germaniae historica.* In the English law of conveyancing a "monument" is an object fixed in the soil, whether natural or artificial, and referred to in a document, and used as evidence for the delineation of boundaries or the situation of a particular plot of land, etc.

For a description of various kinds of monuments *see* such articles as Archaeology; Stone Monuments, Primitive; Effigies, Monumental; Sculpture; Barrow; Cromlech; etc.; many particular monuments such as Stonehenge, are treated under their respective names, or in the articles on the towns, etc. in which they stand; while the preservation of monuments in various countries is dealt with under the different headings of those countries, *e.g.,* Egypt, Greece.

The present article deals with the preservation, by government action, local or central, of the evidences and remains of past history and civilization; for reference to similar action extended to sites and places of natural beauty and interest, which are known in Germany as *Naturdenkmäler* (natural monuments), consult

Meyers Lexicon, s.v. In 1897 was issued a report (C. 8443, *Miscell. Reports, 2*) from British representatives abroad as to "the statutory provisions existing in foreign countries for the preservation of historical buildings"; while in 1905 *The Care of Ancient Monuments,* by G. Baldwin Brown was published containing an ample bibliography for each country and giving many references to various periodicals in different languages: reference may also be made to *The Care of Natural Monuments* (Cambridge, 1909) by H. Conwentz, Prussian State Commissioner for the Care of Natural Monuments.

The chief question at issue is, how far does the national artistic or historic interest of a monument, in the widest sense of the word, justify the interference of the State with the right of a private owner, whether corporate body or individual, to do what he likes with his own? Nearly every European country has given a decided answer to this question, and it may be noticed, as showing the extreme reluctance to State interference in Great Britain, that a clause, laying on an owner of a monument scheduled under the Monument Act of 1882 the obligation of offering it for purchase to the State if he wished to destroy it, was struck out of that Act.

The main lines followed by legislation or regulation for the preservation of monuments may be briefly indicated. Central organizations of commissions and conservators, with a staff of architects, inspectors, and archaeological or artistic experts for consultation, are established. These may have wide legal powers of enforcing their decisions, or may act chiefly by advice or persuasion. The national treasures are catalogued and scheduled, and the value estimated in an exhaustive inventory, in many cases supplemented by local inventories, a course of procedure that has to a large extent prevented the continuance of the destruction of valuable monuments through ignorance of their value.

The Classement System.—A special form of inventory, carrying with it legal consequences, is that known as the *classement* system; of this form the French is the typical example. In this only the outstanding monuments find a place, and such either become national property altogether, or the protection and preservation is undertaken by the State, or may be left in the hands of the private owner; but in any case the monument cannot be destroyed, restored or repaired without the consent of the central authority. The *classement* system has been criticized as tending to depreciate the consideration paid to such monuments as do not appear in the list—*monuments non-classés.* Great Britain adopted a narrow kind of *classement* in the schedule attached to the 1882 Act. Most States have powers of expropriation or compulsory purchase of private property on grounds of public utility, and English law is no exception—as in the case of the compulsory purchase of land for railways—and now the majority of States have made the protection of monuments a matter of public utility. Further, the exportation of artistic or historic treasures, *i.e.,* movable monuments, has been controlled by the State, notably in the case of Italy and Greece, Turkey and Egypt.

Connected with this side of the question is the control by the State of excavations undertaken by private persons, even on their own property. In Germany considerable protection is effected by the powers given to municipalities to make by-laws, respecting not only the preservation of the monuments, but also the erection of new buildings that may interfere with the monuments or with the general characteristic appearance (*Stadtbild*) of the town. This is also the case in Italy, where there are frequent regulations as to town-planning (*piano regolamento*).

The following is a brief account of the measures adopted in the principal countries of the world for the preservation and protection of their artistic and historic treasures.

Great Britain.—In Great Britain the existing law is contained in the Ancient Monuments Consolidation and Amendment Act, 1913. This Act consolidated the provisions of the previous Acts passed in 1882, 1900 and 1910. The act of 1882, due primarily to Lord Avebury, then Sir John Lubbock, provided that a list of monuments in Great Britain and Ireland should be made to which the Act was to apply; the number of these monuments, the names of which will be found in an appendix to Sir R. Hunter's *Lecture on the Preservation of Places of Interest and Beauty* (1907), was 68, all being of the kind known as prehistoric (barrows, stone-circles, dolmens, etc.) An owner of one of these scheduled monuments might by deed place it in the guardianship of the Commissioners of Works, who were then responsible for its preservation and could protect it even against the owner. The Commissioners might purchase any of the scheduled monuments, but only by agreement, the compulsory clauses of the Lands Clauses Consolidation Acts being expressly excluded, though any purchase was to be made under those acts. An owner of any monument other than those scheduled might place it in the care of the commissioners. The funds for the working of the act were to be provided by parliament, and an inspector of ancient monuments was appointed. General Pitt-Rivers, the first inspector, found that without compulsory powers the act was useless, and for many years did not draw his official salary, while after his death in 1900 the office was left unfilled until 1910. In an Act applying only to Ireland, which was passed in 1892, the commissioners of public works in Ireland were given powers—only to be exercised with the consent of the owner—of applying the act of 1882 to any monument possessing such public interest as might render it worthy of preservation. It is to be noticed that after the disestablishment of the Irish Church certain unused churches of artistic or historic interest were placed in the charge of the Commissioners as national monuments, with a sum of £50,000 to defray expenses. The Irish Commissioners have therefore monuments in their care other than those scheduled in the Acts, and may apply towards the expenses of the preservation of the scheduled monuments any surplus over from the fund above mentioned. The act of 1900 applied the Irish act to Great Britain, and also gave the powers of the Act of 1892 to county councils, allowed the authorities, local or central, to make arrangements for the preservation of monuments with owners or others, including societies, and to receive subscriptions for the same object, and also provided for public access to such monuments as are in the guardianship of the Commissioners under the Act. The Acts of 1892 and 1900, though allowing buildings of historic or other interest to be placed under the care of the commissioners, excluded buildings occupied as a dwelling-place by any person other than a caretaker and his family. The act of 1910 gave to the Commissioners of Works power to acquire by *bequest* buildings of historic or architectural interest. The act of 1900 had given power to acquire such by gift or purchase, and the act of 1882 had given power by bequest also, but only referred to prehistoric remains. The London County Council possesses powers of purchasing by agreement any building of historic or other interest under a General Powers Act of 1898, and exercised these in 1899 by purchasing, in conjunction with the City Corporation, the 17th century house in Fleet Street in which is the room known as "Prince Henry's Council-chamber."

Under the Consolidating Act of 1913 Ancient Monuments Boards were set up for England, Scotland and Wales whose duty is to advise the Commissioners of Works with reference to the treatment of monuments and to report to the Commissioners when they have reason to believe that any monument of national importance is in danger of destruction or removal, or danger from neglect or injudicious treatment. A "monument" or "ancient monument" is defined as including any structure or erection (except an ecclesiastical building for the time being used for ecclesiastical purposes) the preservation of which the Commissioners of Works consider to be a matter of public interest because of its historic, architectural, traditional, artistic, or archaeological importance. The Commissioners, however, may not accept the guardianship of, or issue a preservation order relating to, any monument occupied as a dwelling-house by any person other than the caretaker thereof. They are bound to prepare and publish a list of all monuments the preservation of which is reported by any of the Ancient Monuments Boards to be of national importance, and to inform the owners of their intention to include them and of the penalties incurred for injury or defacement. This is called "scheduling" a monument. The owner of such a monument is

thereafter bound to give the Commissioners one month's notice before he proceeds to demolish, remove (either whole or in part), alter structurally, or make any addition to the monument. Failure to give such notice renders him liable on summary conviction to a fine not exceeding £100, or to imprisonment for three months, or to both.

The Commissioners of Works, or any local authorities within the meaning of the Act, have power (1) to acquire ancient monuments by purchase; (2) to accept the ownership of an ancient monument under a deed of gift or a will; (3) to assume the guardianship of any ancient monument offered to them by the owners.

Where the Commissioners or a local authority acquire or accept a monument they become the legal owners of the buildings and the land on which they stand. Where the Commissioners only assume guardianship, the ownership remains vested in the original owners, though the Commissioners or the local authority, as the case may be, have powers of control and maintenance over it as an ancient monument apart from the owner. The Commissioners of Works may, in the case of any monument of which they are not owners or where they are not guardians, issue a preservation order if the Ancient Monuments Board concerned reports to them that any monument which the Board consider to be of national importance is in danger of destruction, removal or damage from neglect. In very urgent cases the Commissioners may make such an order without receiving a report. A preservation order has effect only for eighteen months unless within that time the order has been confirmed by Parliament, and while it is in force the monument must not be demolished or removed, nor may any additions or alterations be made without the Commissioners' written consent. If no confirmation is made, no further order with regard to the monument can be made for five years. The Commissioners of Works are bound to afford public access to any monument of which they are the owners; but where they are only guardians the public are not entitled to access without the owner's consent, if the deed of guardianship so provides. Persons injuring or defacing any monument of which the Commissioners or a local authority are guardians or which is subject to a Preservation Order, may, on summary conviction, be fined a sum not exceeding £5 and be ordered to repay the cost of repairing the damage, or imprisoned with or without hard labour, for a term not exceeding one month.

Towards the making of a national inventory the first step taken was the appointment in 1908 of three royal commissions, for England, Scotland and Wales respectively, "to make an inventory of the ancient and historical monuments and constructions connected with or illustrative of the contemporary culture, civilization and conditions of life of the people from the earliest times" to the year 1700 in the case of England and 1707 in that of Scotland (for Wales no date is specified), and "to specify those which seem worthy of preservation." The Housing Town-planning Act and the Development and Road Improvement Funds Act (both 1909), excepted the sites of ancient monuments or of other objects of historical interest from compulsory acquisition for the purposes of those Acts. The Finance Act of 1896 granted a qualified exemption from estate duty to pictures, prints, books, mss., works of art, scientific collections and other things not yielding income, as appear to the Treasury to be of national, scientific or historic interest; this exemption only extends where such property is settled to be enjoyed in kind in succession by different persons; if the property is sold or is in the possession of a person competent to dispose of it, it becomes liable to estate duty. The Finance Act of 1909 extended the exemption to legacy and succession duty, removed the restriction to settled property and added "artistic" to "national and historic interest."

Apart from the numerous national and local (usually county) archaeological societies whose proceedings contain invaluable accounts of practically every monument of interest throughout the kingdom, there are three societies directly formed with the object of monument preservation in its widest sense, the Society for the Protection of Ancient Buildings, founded in 1877, the Ancient Monuments Society, with headquarters at the John Rylands Library, Manchester, and the National Trust for Places of Historic Interest or Natural Beauty, which was founded in 1895 with the object of generally promoting the preservation—and particularly the acquisition by gift or purchase—of places of historic interest or natural beauty and holding them in trust for the nation. The last-named was incorporated by the National Trust Act in 1907 and was by that Act empowered to acquire by gift, purchase or devise, sites and buildings to be held in perpetuity for the benefit of the public. It possesses more than 150 properties, amounting to nearly 30,000 acres, and including 30 interesting buildings, among which are the Joiners' Hall at Salisbury, the Old Court House at Long Crendon (Bucks), the Coleridge Cottage at Nether Stowey, and Duffield, Kanturk, Bodiam and Tattershall castles.

In 1926 the Government of Northern Ireland passed an Act modelled very largely on the British Act of 1913.

In the Report of the Ancient Monuments Advisory Committee issued in 1921, it is stated that "legislation for the protection of national monuments in this country [Great Britain] is a thing of very modern growth, as may be realized from the fact that 20 years ago the State could only exercise a very ineffective control over a limited class of prehistoric monuments, while for the care of the great architectural monuments of the country there was no State provision of any kind. The Acts of 1910 and 1913 have considerably improved the position. But even at the present day the conception of the nation's interest in, and consequent duty towards, national monuments is far behind what is embodied in the legislation of other countries, and numbers of monuments of the very first importance are entirely without protection, as far as statutory powers are concerned. The existence, however, of these Acts is in itself a recognition of the principle that the nation has an interest in Ancient Monuments apart from, and in some respects superior to, the interests of the legal owners of the monuments." In the summary of their conclusions, the members of the Advisory Committee said, "It appears that while the definition of a monument is everywhere much the same, a distinction is made in practice between monuments in private ownership and those belonging to public or corporate bodies. The British distinction between monuments in use and those no longer used is not recognized [on the Continent], and we are of the opinion that on logical and practical grounds the advantage is with the Continental conception. Other provisions which are not found in the British law are (1) control of movable objects, (2) preservation of scenery where it affects the amenities of a monument, (3) financial help to private owners for the preservation of monuments in their possession and (4) compensation."

It is of interest to compare the protective measures adopted by certain other countries with those in force in Great Britain.

France.—In France a monument is defined as any movable or immovable object the preservation of which is of public interest from an historical or artistic point of view. If a monument is in danger and the owner will take no action to preserve it, it may be placed under the direct control of the State. This function is termed scheduling and is performed by the Ministry of Fine Arts, becoming immediately operative on notification. If the owner objects, the scheduling must be confirmed by a decree of the Council of State, and compensation is payable if considered due. The owner must lodge his objection within six months. A scheduled monument, if belonging to a public body, may not be alienated without permission, and whether public or private may not be in any way damaged. Penalties are provided.

The Ministry of Fine Arts, or Departments or Communes, may, if it seems to them necessary, expropriate monuments of public interest at an agreed price; but confirmation of this is necessary within six months by a decree of the Council of State declaring public benefit.

Germany.—In Germany, all objects are included which are characteristic of their times, are of value for the understanding of art and its historical development and of history in general or serve to record important historical events. Monuments may be movable or immovable, and everything which is not the property of private persons may come under the law, including all churches and public buildings and the property of universities

and other corporate bodies recognized by the State. Private property is dealt with under the general laws governing building, the State inspectors having to take care that no scheme for new buildings, or building operations of any importance, shall cause damage or disfigurement to ancient monuments. Grants of money are sometimes made to public or private owners to assist them in preserving their monuments, the State reserving, in such cases, a certain amount of control and supervision over the monument for the future. The principal German society is the Gesamtverein der deutschen Geschichts- und Altertumvereine, founded in 1852. This is a general association of all the various societies throughout Germany. There are also many societies in the various towns, as well as local associations more directly concerned with the practical protection and preservation of monuments. The chief periodical—perhaps one of the most important of any dealing with the subject in Europe—is *Die Denkmalpflege,* first published in 1899.

India.—The Archaeological Survey of Upper India was established in 1862, with a director-general at its head, and surveys for other parts of India were also begun later. The chief object of these was the making of an inventory, and the preservation of the monuments was neglected. In 1878 a curator of ancient monuments was appointed. A period of activity with regard to monument preservation set in during the Viceroyalty of Lord Curzon (1899–1904); this culminated in the Ancient Monuments Preservation Act (1904). Besides establishing and placing on a permanent footing the seven "Archaeological Circles" into which British India is now divided this Act empowered the local government of any province to declare any monument to be a "protected monument within the meaning of the Act," and provided that when any monument was thus scheduled no one might injure, remove or alter it under penalty of a fine or imprisonment. Power of expropriation is accorded by the Land Acquisition Act in any case in which a monument is threatened with destruction or injury, or if an owner refuse to come to an agreement with the authority for its guardianship. The Act includes movable antiquities, and the governor-general in Council can prohibit their exportation; control over excavations is also given.

Bibliography.—Besides the Reports and works by G. Baldwin Brown, H. Conwentz, Sir Robert Hunter, and others to which reference is made in the text, *see* the seven *Lists of Scheduled Monuments* issued from the office of H. M. Commissioners of Works, *The Ancient Monuments Consolidation and Amendment Act,* ed. by Henry Jenner, F.S.A. (1913), and the publications of the Royal Commission on Historical Monuments. (S. H. H.; X.)

United States.—With regard to the remains of prehistoric man, earthworks, barrows, etc., some of those States, such as Ohio, which are especially rich in such monuments, have particular laws protecting individual remains, *e.g.,* the earthworks in Warren county. The State exercises control over other remains of interest, *e.g.,* the Eagle earthworks in Licking county. There is also an archaeological and historical society, partly maintained by the State, with the object of the better preservation of the evidences of the prehistoric occupation. In North Dakota a State historical commission was created in 1895 "to collect and preserve the records and relics pertaining to the early history, settlement and development of North Dakota." The sites of the battlefields and statues, etc., erected in commemoration of the War of Independence or the Civil War, are preserved by various methods—by State or municipal regulations, by the action of incorporated bodies or trustees, etc. Most of the States rely on statutory prohibitions of malicious damage to protect their monuments. The Federal Government has set aside various natural features and historic spots as national monuments. *See* National Parks and Monuments, The.

MONVEL (1745–1812), French actor and dramatic writer, whose real name was Jacques Marie Boutet, was born in Lunéville on March 25, 1745. He was a small, thin man without good looks or voice, and yet he became one of the greatest comedians of his time. He made his début in 1770 at the Comédie Française in *Mérope* and *Zénaïde;* he was received *sociétaire* in 1772. For some reason unknown Monvel secretly left Paris for Sweden about 1781, and became reader to the king, a post which he held for several years. At the Revolution he returned to Paris, embraced its principles with ardour, and in 1791 joined the theatre in the rue Richelieu (the rival of the Comédie Française), which, under Talma, with Dugazon, his sister Mme. Vestris, Grandmesnil (1737–1816) and Mme. Desjardins, was soon to become the Théâtre de la République. After the Revolution Monvel returned to the reconstituted Comédie Française with all his old companions, but retired in 1807. Monvel was made a member of the Institute in 1795. He wrote six plays (four of them performed at the Comédie Française), two comedies, and 15 comic operas, seven with music by N. Dezède (1740–92), eight with music by Nicolas d'Alayrac (1753–1809). He also published an historical novel, *Frédégonde et Brunehaut* (1776). He was professor of elocution at the Conservatoire. His two daughters (Mlles. Mars, *q.v.*) were well-known actresses.

MONZA (locally *Monscia*), city, Lombardy, Italy, in the province of Milan, by rail, 8 m. N.N.E. of Milan, with which it is also connected by both steam and electric trams. It lies on the Lambro, a tributary of the Po, 532 ft. above sea-level. Pop. (1921), 42,988 (town); 57,060 (commune). Near the Porta d'Agrate is the nunnery in which the nun of Monza (*see* Manzoni's *Promessi sposi*) was enclosed. The cathedral (590) was enlarged at the close of the 13th century, and the black-and-white marble façade was erected in the 14th by Matteo da Campione. On the left is the brick tower, 278 ft. high (1592–1606). Within the church are the iron crown of Lombardy, supposed to have been beaten out of one of the nails used at the Crucifixion, and the treasury containing the relics of Theodelinda (*see* Lombards), comprising her crown, fan and comb of gold, and the golden hen and seven chickens, representing Lombardy and her seven provinces, and crosses, reliquaries, etc., of the Lombard and Gothic periods. The church of Santa Maria in Istrada (1357) has a rich terra-cotta façade of 1393. The communal palace has pointed arches and a square tower. The royal palace of Monza (1777) lies not far from the town, on the banks of the Lambro, and is used for art exhibitions. A motor-racing track has been constructed in the park.

Monza (anc. *Modicia*) was a village until the time of Theodoric. During the period of the republics Monza was sometimes independent, sometimes subject to Milan. The Visconti built a castle in 1325. Monza has stood 32 sieges, and was repeatedly plundered—notably by the forces of Charles V. At Monza King Humbert I. was assassinated on July 20, 1900; an expiatory chapel was dedicated in 1910.

MONZONITE, the group-name of a type of rocks which have acquired it from their most celebrated occurrence, that of Monzoni in Tirol. The rocks are of granitic appearance, usually rather dark grey in colour and fine to moderately coarse grained. The special characteristic which distinguishes them from granites and ordinary syenites is the presence of basic plagioclase and orthoclase felspars in nearly equal amounts. Labradorite and andesine are present, usually in well-shaped crystals, often zoned; orthoclase forms large irregular plates in which the other minerals are embedded. There is rarely any considerable amount of quartz, though in a few of these rocks this mineral occurs (the quartz-monzonites). Other features are the abundance of augite, and of large bronze-coloured plates of biotite which are of quite irregular shapes and full of enclosures. Hypersthene or bronzite is less common, but hornblende is sometimes abundant. Olivine also may be present; when the rock contains this in notable quantity it may be called an olivine-monzonite.

The monzonites of Tirol show a great variability in appearance, structure and the relative proportions of their minerals. They tend to pass into iolesites and gabbros, and near the margins of the outcrop occur facies very rich in pyroxene (pyroxenites).

Rocks of monzonitic facies occur also in Norway, where they have been described as åkerites. They contain quartz, orthoclase and plagioclase, augite and biotite; hornblende and hypersthene also may be present. Some of them have porphyritic rather than granitic texture, especially near the margins of the laccoliths. From a study of these and other occurrences Brögger proposed to define the monzonites as orthoclase-plagioclase

rocks in which the two chief classes of felspar occur in nearly equal quantities (as distinguished from the orthoclase rocks or granites and syenites and the plagioclase rocks or diorites and gabbros).

At Yogo Peak and Beaver Creek, Montana, there are masses of granitoid rock which bear a close resemblance to the monzonites of Tirol. Two main types occur: (*a*) yogoite, which differs little from monzonite, and (*b*) shonkinite, which is a more basic rock richer in plagioclase and augite; this rock contains olivine and in places passes into dark pyroxenites. In shonkinite also a little nepheline may be present. In the west of Scotland intrusive bosses are known which consist of an olivine-bearing rock closely related to monzonite. It has been called kentallenite because it is quarried at Kentallen in Argyllshire.

The following analyses show the chemical peculiarities of the principal rocks of the monzonite group:—

	SiO_2	Al_2O_3	Fe_2O_3	FeO	MgO	CaO	K_2O	Na_2O
Monzonite, Monzoni .	54·20	15·73	3·67	5·40	3·40	8·50	4·42	3·07
Yogoite, Yogo Peak .	54·42	14·28	3·32	4·13	6·12	7·72	4·22	3·44
Kentallenite, Argyllshire .	52·09	11·93	1·84	7·11	12·48	7·84	3·01	2·04

(C. E. T.)

MOODKEE or **MUDKI,** a town in the Ferozepore district of the Punjab, India. It is situated 26 m. S. of the Sutlej, on the old road from Ferozepore to Karnal, and is notable as the scene of the first battle (Dec. 18, 1845) in the first Sikh war (*q.v.*).

MOODY, DWIGHT LYMAN (RYTHER) (1837–1899), American evangelist, was born in the village of East Northfield, Mass., on Feb. 5, 1837. His father died in 1841, and young Dwight, a mischievous, independent boy, got a scanty schooling. At 17 he became a salesman in a shoe-store in Boston; in 1855 he was "converted"; and in 1856 he went to Chicago and started business there. Beginning with a class gathered from the streets, he opened (1858) a Sunday school in North Market hall, which, largely as a result of his enthusiasm and devotion, grew into a church. He was a man of extraordinary energy and of never failing belief in the power of the Lord to provide. In 1860 he gave up business and devoted himself to city missionary work, and during the Civil War to labours among the soldiers. In 1865–69 he was president of the Chicago Young Men's Christian Association. Ira David Sankey (1840–1908) joined him in Chicago in 1870 and helped him greatly by the composition and sympathetic rendering of the Moody and Sankey *Gospel Hymns*. In a series of notable revival meetings in England and America these two men carried on their campaign, which, according to Moody's admirers, "reduced the population of hell by a million souls." In 1879 Moody opened the Northfield seminary for young women at Northfield, Mass., and in 1881 the adjacent Mount Hermon school for boys; in each a liberal practical education centred about Bible training. In 1889 he opened in Chicago the Bible institute, and there trained Christian workers in Bible study and in practical methods of social reform; he was also the founder of the Bible (or Christian Workers') conference, first held at Northfield in 1880, and the Students' (or College Men's) conference, first held in 1887. He died at Northfield on Dec. 22, 1899. His sermons were colloquial, simple, full of conviction and point. In his theology he laid stress on the Gospel, not on sectarian opinions. His intense sympathy for, and insight into the individual, his infinite practical skill and tact, his genius for organization, his honesty, his singular largeness and sweetness of spirit and his passion for mending and winning souls made him, in spite of his scholastic defects, one of the greatest of modern evangelists.

See the (official) *Life of Dwight L. Moody* (1900), by his son, W. R. Moody; Henry Drummond, *Dwight L. Moody: Impressions and Facts* (1900), with an introduction by G. A. Smith; and Gamaliel Bradford, *D. L. Moody, a Worker in Souls* (1927), which contains a bibliography.

MOODY, WILLIAM VAUGHN (1869–1910), American poet and playwright, was born at Spencer (Ind.), July 8, 1869. After the death of his parents he worked his way through preparatory school and Harvard, where he acted as assistant in English in 1894–95. From 1895 to 1903 he was an instructor at the University of Chicago and, after 1901, an assistant professor. Teaching, the editing of Milton's poems and other classics, and the compilation with Robert M. Lovett of *A First View of English and American Literature* (1902), he endured only as they enabled him to help his family and to secure the leisure he coveted for creative work. He died at Colorado Springs, Oct. 17, 1910. For a time *The Great Divide* (1907) was hailed as "the great American drama," and it still ranks high. His second prose play, *The Faith Healer* (1909), although the material was interesting, was less successful dramatically. His remaining output was verse—a number of short pieces collected first in 1901 and the poetic dramas *The Masque of Judgment* (1900) and *The Fire-Bringer* (1904). The last of the trilogy *The Death of Eve* was left incomplete at his death. Moody had a genuine gift for song, which he carefully cultivated. The richness of his rhythms and the fineness of his lyric sense gave him a high place in American literature.

In 1912 Moody's complete works in three volumes were edited with an admirable introduction by J. M. Manly. *Some Letters of William Vaughn Moody* (1913), edited by D. G. Mason, forms the best possible revelation of his brilliant gifts, of his moods, and of his life during his working years.

MOON, in astronomy, the name given to the satellite of any planet, specifically to the satellite of the earth (a common Teutonic word, *cf.* Ger. *Mond,* Dut. *maan,* Dan. *maane,* etc., and cognate with such Indo-Germanic forms as Gr. *μήν*, Skt. *mās,* Irish *mī,* etc.; Lat. uses *luna, i.e., *lucna,* the shining one, *lucere,* to shine, for the moon, but preserves the word in *mensis,* month; the ultimate root for "moon" and "month" is usually taken to be *me-*, to measure, the moon being a measurer of time).

The Apparent Motion of the Moon.—It is convenient to give first a general idea of the motion of the moon as seen by an observer on the earth. The sidereal month is 27·32 days and in this interval the moon makes, on the average, a complete revolution relative to the stars. In the meantime, the earth is moving in its orbit round the sun and it is not till after the lapse of an additional 2·21 days that the moon is in the same position relative to the sun's direction; the synodic month being 29·53 days.

The moon being an opaque body, shining by reflected light, only that portion of the hemisphere which is illuminated and turned towards the earth can be seen. At new moon, M^1, the hemisphere turned towards the earth is wholly unilluminated by sunlight, while at full moon, M^5, the fully illuminated hemisphere is turned towards the earth. At intermediate phases the hemisphere turned towards the earth is only partially illuminated. Near new moon (on both sides) the moon appears as a narrow crescent with the horns turned away from the sun; near full moon the defective edge is that farthest from the sun's direction, *i.e.*, before full moon the eastern side (left in northern hemisphere) and after full moon the western side. In the diagram the plane of

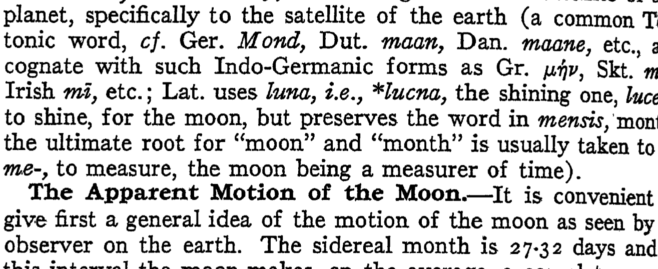

DIAGRAM OF THE PHASES OF THE MOON (M), SHOWN IN EIGHT POSITIONS

The part shown white is illuminated by sunlight, and the phase of the moon is determined by the position of the illuminated hemisphere relative to the direction of the line joining the moon and the earth (E)

the paper may be taken as that of the earth's motion round the sun. The moon's orbit does not lie exactly in this plane but is inclined to it at an angle of about 5°. If this were not so the moon would eclipse the sun at every new moon and would itself be eclipsed by the earth at every full moon. The line NN^1 may be taken as representing the line of intersection of the two planes. This line, known as the line of nodes, is in slow rotation, making about one revolution against the arrows in about 18·6 years. At two seasons each year the sun is near the direction of NN^1 as seen from the earth, and at these seasons eclipses occur. (*See*

THE MOON AND ITS CRATERS

These illustrations show the craters (presumably similar to the earth's volcanic craters) with which the moon is pitted, and the dark plains which are called "seas" although actually there is no water on the moon's surface. 1. Moon at first quarter. 2. South Pole and Mare Nubium. 3. Mare Imbrium. 4. The crater Copernicus, showing radiating faults

illustrations and article ECLIPSE.)

To understand the positions in which to expect the moon at any time it is most convenient to consider its position relative to the sun. When the moon is new it is in the same direction as the sun. Consequently it rises and sets with the sun, crosses the meridian with the sun and cannot be seen from the earth. Relatively to the stars the sun moves eastward about 1° per day, while the moon moves about 13° in the same direction. The moon, therefore, appears about 12° farther east of the sun day by day, and 13° farther east of the stars in its neighbourhood. When the moon is one day old it will lie about 12° east of the sun, it will be due south about 48 minutes after the sun and it will describe in the sky the same arc as the sun will do about 12 days later, if it is assumed, as is approximately true, that the orbital planes of the sun and the moon coincide. Similarly when the moon is at first quarter or 90° east of the sun it will be due south 6 hours after the sun and it will describe in the sky the same arc as the sun will describe in three months' time. Consider the case of a moon a week after new on March 21. On that day the sun will rise six hours before noon and set six hours after. At sunset the moon is due south and in the position occupied by the sun at noon on June 21. Consequently, for observers in the northern hemisphere, it will be more than 12 hours above the horizon, rising more than 6 hours before it souths. In the latitude of London it will rise about 8½ hours before it souths, *i.e.*, about 9.30 A.M., and it will not set till about 2.30 the next morning. As is well known, in fairly high north latitudes, the moon near the full rises at nearly the same hour for several nights in the autumn, giving rise to the phenomenon of the harvest moon. The explanation of this is very simple. The full moon in the autumn is in the same part of the sky as the sun is in the spring. Now, in the spring, the time the sun is above the horizon is steadily increasing from day to day. This is happening for the autumn full moon 13 times as fast. Consequently, although on the average the moon is 48 minutes later day by day in southing, its rising is not retarded by anything like this amount. In the spring the phenomenon is reversed, and the rising of the full moon is delayed by more than 48 minutes from day to day. Referring to the diagram, it will be seen that when the moon is near the position M^1 although the hemisphere turned towards the earth is not illuminated directly by sunlight it is illuminated indirectly by light from the illuminated hemisphere of the earth. This light must be about 12 times as bright as the full moon and consequently near the time of new moon, after twilight, the whole hemisphere of the moon can be seen faintly illuminated by "earthshine." This phenomenon can be seen very well in a small telescope.

The moon always presents nearly the same face to the earth, from which it follows that, when referred to a fixed direction in space, it revolves on its axis in the same time in which it performs its revolution. The rate of actual rotation is substantially uniform, while the arc through which the moon moves from day to day varies somewhat. Consequently, the face which the moon presents to the earth is subject to a corresponding variation, the globe, as seen from the earth, slightly oscillating in a period nearly equal to that of revolution. This apparent oscillation is called *libration* and its amount on each side of the mean is commonly between 6° and 7°. There is also a libration in latitude, arising from the fact that the axis of rotation of the moon is not precisely perpendicular to the plane of its orbit. This libration is more regular than that in longitude, its amount being about 6° 44′ on each side of the mean. The other side of the moon is invisible from the earth, but in consequence of the libration about six-tenths of the lunar surface may be seen at one time or another, while the remaining four-tenths are forever hidden from view. It is found that the direction of the moon's equator remains nearly invariable with respect to the plane of the orbit, and therefore revolves with that plane in a nodal period of 18·6 years. This shows that the side of the moon presented to observation is held in position, as it were, by the earth, from which it also follows that the lunar globe is more or less elliptical, the longer axis being directed toward the earth. The amount of the ellipticity is, however, very small.

MOON'S SURFACE

The surface of the moon has been a subject of careful and continuous telescopic study from the time of Galileo. The early observers seem to have been under the impression that the dark regions might be oceans; but this impression must have been corrected as soon as the telescope began to be improved, when the whole visible surface was found to be rough and mountainous. The work of drawing up a detailed description of the lunar surface and laying its features down on maps has from time to time occupied telescopic observers. The earliest work of this kind, and one of the most elaborate, is the *Selenographia* of Hevelius, a magnificent folio volume. This contains the first complete map of the moon. Names borrowed from geography and classical mythology are assigned to definite regions and features. A system was introduced by Riccioli in his *Almagestum novum* of designating the more conspicuous smaller features by the names of eminent astronomers and philosophers, while the great dark regions were designated as oceans, with quite fanciful names: *Mare imbrium, Oceanus procellarum,* etc. This nomenclature has been retained. With the improvement of the telescope more extended maps based on drawings and measurements were constructed by J. H. Schröter of Lilienthal, and by W. Beer and J. H. Mädler in the nineteenth century. The application of photography to astronomy has greatly simplified the recording of lunar formations. Pioneer work was done by J. W. Draper of New York as early as 1850 followed by Bond at Harvard, De la Rue in England and Rutherford in New York. Excellent photographs have been taken at a number of observatories including Lick and Paris. A whole volume of Harvard *Annals* (vol. LI.) is devoted to photographs of the moon showing different portions with varying illumination.

The moon as seen by the naked eye is a beautiful object with bright and dark patches, but as seen in even a small telescope it is magnificent and the various formations stand out as in the photographs. The most interesting time to watch the moon with a telescope is near half moon. The boundary between the bright and dark portions, known as the terminator, then shows a very rugged appearance and even a short stay at the telescope enables one to watch the sun's light catch new mountain peaks. On account of the nearness of the moon it is possible with large telescopes to see objects less than a mile in diameter. The most striking formations on the moon are the craters, which are of all sizes up to 100 miles or more in diameter and are scattered over the surface with great profusion, frequently overlapping. These craters in appearance closely resemble the volcanic craters on the earth, and it is possible that they have a similar origin. They have, however, often so large a diameter compared with height that the analogy may not be so close as at first appears. The typical crater has a surrounding ring rising to anything up to 20,000ft. above the general level. The floor of the crater may be higher or lower than the outside level. Often there may be a central peak or peaks within the crater. The darker areas which are not so much covered by craters have been considered to be seas of lava which have spread over the moon's surface at a later date than that of the formation of most of the craters. Other striking features on the moon are streaks or rays which radiate from a number of craters to many hundreds of miles.

As the moon is devoid of air and water there can be no meteorological variations of the kind experienced on the earth. Changes on the moon's surface could therefore be produced only by the direct action of the sun's rays. It is at once evident that there must be an enormous range in the temperature of the surface rocks of the equatorial regions of the moon which are alternatively exposed to 15 days of solar radiation and then to 15 days of darkness. During the last century attempts were made by Lord Rosse, S. P. Langley and others to measure the moon's heat, but the apparatus available was not sufficiently sensitive. Recently, however, bolometers of sufficient sensitivity have been constructed to measure not only the total heat from the moon, but that in different wave-lengths.

Brightness of the Moon.—Many attempts have been made to estimate the brightness of the moon in comparison with the sun and the stars. The results obtained by Sir John Herschel,

Bond, Zöllner, Pickering and others show a range of over 20%; but the mean result indicates that the sun is about 465,000 times brighter than the average full moon. On account of the varying distance of the moon from the sun and the earth there must be a real variation of over 20%. The variation of the brightness of the moon with its phase is complicated by the nature of the surface and the varying angle of incidence of the sun's light. Although at first quarter half of the hemisphere turned towards the earth is illuminated, it appears only $\frac{1}{8}$ to $\frac{1}{9}$ as bright as full moon and at third quarter it is only $\frac{1}{10}$ as bright. This is only partly due to the fact that near the terminator the sun's rays strike the surface very obliquely. The greatest cause of the relative faintness of the half moon must be the unevenness of the moon's surface so that an important fraction of the surface is in the shadow. The amount of sunlight reflected by the moon is only about one-fourteenth of the total sunlight falling on it. This is a small fraction compared with that for cloud-bound planets, but it is of the order to be expected from a body with no atmosphere and with a rocky surface. Of course, this is only an average value and different areas of the moon differ widely in reflecting power. E. C. Pickering in America was the first to determine the relative brightness of different parts of the moon, and his work has been continued by European observers. They find that the darkest parts of *oceanus procellarum* and *mare crisium* reflect only $\frac{1}{8}$ as much as the very bright crater *Aristarchus.*

The total brightness of the moon is reckoned as equal to about one-quarter of a meter-candle, equal, that is, to a 100 candle-power lamp at a distance of 22 yards.

Constants of the Moon's Size and Motion.—

Synodic month (relative to sun)	29·53059 days

LUNAR THEORY

Historical.—In ancient times the moon was a very important body for night illumination and a great deal of attention was given to its motions. The observations made were of an exactitude far in advance of those in other physical sciences. Hipparchus (2nd century B.C.) discovered the eccentricity of the moon's orbit and the motion of the apse. The inclination of the orbit to the ecliptic and the motion of the node were also determined by him. He explained the motion of the moon as uniform in a circular orbit with the earth placed eccentrically and this was amply sufficient for the observations of that time. The numerical values were derived from observations of eclipses. For fixing the quantities which require the lapse of long intervals of time for their accurate evaluation he made use of the oldest eclipse observations available. At the times of eclipses the inequality in longitude due to eccentricity cannot be separated from an important solar perturbation called the evection. Consequently, he got a value of the eccentricity in longitude (true value 6° ·29) erroneous by the amount of the evection (1°·27). The latter inequality was discovered by Ptolemy (fl. A.D. 140). No great improvement in the knowledge of the moon's motion was made, except for slightly improved accuracy in the mean motions till Tycho Brahe (1546–1601) discovered another inequality due to solar attraction, called the variation, which has greatest effect when the moon is 45° or 135° distant from the sun on either side. The coefficient of this term is 0°·66. The explanation of all these inequalities and the construction of an adequate theory of the moon's motion had to wait the discovery of universal gravitation.

Gravitational Theory.—Newton's theory of gravitation was based largely on the comparison of the motion of the moon with bodies falling freely on the earth. The portion of the *Principia* which specially refers to the motion of the moon is contained in propositions 22, 25–35 of book iii. Newton succeeded in proving that the principal periodic inequalities as well as the mean motions of the perigee and node were due to the sun's action, and he added some other inequalities which had not been deduced previously from observation. The result which he obtained for the mean motion of the perigee was only about half the observed value, but it appears from manuscripts that are extant that he succeeded later in explaining the observed motions within 8%. Newton's results were given in a geometrical form but he probably first obtained them by the method of fluctions. No substantial advance was made on Newton's work till Clairaut developed his analytical theory 60 years later. Clairaut's work was followed by that of d'Alembert and Euler in the eighteenth century. A new epoch in the theory was then opened by the work of Laplace.

The analytical methods which have been developed may be divided into three classes.

(1) Laplace and his immediate successors, especially Plana, effected the integration by expressing the time in terms of the moon's true longitude. Then, by inverting the series, the longitude was expressed in terms of the time.

(2) By the second general method the moon's co-ordinates are obtained in terms of the time by the direct integration of the differential equations of motions, retaining as algebraic symbols the values of the various elements. Most of the elements are small numerical fractions: e the eccentricity of the moon's orbit, about 0·055; e', the eccentricity of the earth's orbit, about 0·017; γ, the sine of half the inclination of the moon's orbit, about 0·046; m, the ratio of the mean motions of the earth and moon, about 0·075. The expressions for the longitude, latitude and parallax appear as infinite trigonometric series, in which the coefficients of the sines and cosines are themselves infinite series proceeding according to the powers of the above small quantities. This method was applied with success by Pontécoulant and Sir John Lubbock and afterwards by Delaunay.

(3) The third method seeks to avoid the difficulty by using the numerical values of the elements instead of their algebraic symbols. This method has the advantage of leading to a more rapid and certain determination of the numerical quantities required. It has the disadvantage of giving the solution of the problem only for a particular case, and of being inapplicable in researches in which the general equations of dynamics have to be applied. It leads, however, to the most accurate results for the motion of the moon.

Amongst the applications of the third method an outstanding place is occupied by the researches of P. A. Hansen. His first work, *Fundamenta nova* appeared in 1838 and contained an exposition of his methods. During the twenty years following he devoted a large part of his energies to the numerical computation of the lunar inequalities, the re-determination of the constants of the motion and the preparation of new tables for computing the moon's position. The importance of these tables was impressed upon the British Government by Airy and they were published by the Admiralty in 1857. The theory was published in *"Darlegung der theoretischen Berechnung der in den Mondtafeln angewandten Störungen."* A peculiarity of Hansen's method is that the angular perturbations in the plane of the orbit are added to the mean anomaly in an auxiliary ellipse. The tables were

brought into use for computing the positions of the moon for the *Nautical Almanac* in 1862 when they replaced Burckhardt's Tables (Paris, 1812). They remained in use till 1922, but Newcomb's corrections were introduced in 1883. These corrections were partly theoretical and partly observational. Amongst the general theories of the second class the most noteworthy is that due to C. E. Delaunay.

A completely new theory and set of tables have been constructed by Professor E. W. Brown of Yale during the present century. The method employed may be briefly indicated. The four small quantities, e, $\acute{e}$, γ and m, have been mentioned. The moon's co-ordinates have to be expressed in terms of the powers and products of these. Euler conceived the idea of starting with a preliminary solution of the problem in which the orbit of the moon was supposed to lie in the ecliptic and to have no eccentricity; while that of the sun was circular. This solution being reached, the additional terms were found which depended on the first power of the eccentricities and of the inclination. Then the terms of the second order were found, and so on to any extent. In a series of remarkable papers published in 1877–1888 G. W. Hill improved Euler's method, and worked it out with much more rigour and detail than Euler had been able to do. His most important contribution to the subject consisted in working out by extremely elegant mathematical processes the method of determining the motion of the perigee. J. C. Adams determined the motion of the node in a similar way. The numerical computations were worked out by Hill only to the first approximation. The work of constructing a complete lunar theory by this method was undertaken by Brown who published his results in the Memoirs of the Royal Astronomical Society during the years 1901 to 1908. Thereafter he determined the numerical constants by comparison with the Greenwich meridian observations for the years 1750 to 1910 as worked up by G. B. Airy and P. H. Cowell. The values finally adopted were published in a series of papers published in the *Monthly Notices* of the Royal Astronomical Society during the years 1913 to 1915. Professor Brown, assisted by H. B. Hedrick, then proceeded with the calculation of the tables which were printed by the Cambridge University Press and published by Yale University Press in three volumes in 1919. By the use of various devices the tabulation was simplified so that although the number of terms included is about 1,500 or about five times that of Hansen's Tables the task of calculating an annual ephemeris is no greater. The effect of every known sensible term is included and many terms are also included which must be classed as insensible in comparison with the best modern observations. The principal constants determined by Brown (*Monthly Notices* of the Royal Astronomical Society, vol. lxxv., p. 510) are given below. The epoch is 1899, Dec. 31, Greenwich mean noon, from which T is computed in Julian centuries of 36,525 days; r denotes a revolution or 360°.

$$\begin{aligned}
\text{Mean longitude} &= 270^\circ 26' 11''.71 \\
&\quad + 1336^r\ 307^\circ 53' 26''.06\ T \\
&\quad + 7''.14\ T^2 + 0''.0068\ T^3 \\
\text{Empirical term} &+ 10''.71 \sin(240^\circ.7 + 140^\circ.0\ T) \\
\text{Longitude of perigee} &= 334^\circ 19' 46''.40 \\
&\quad + 11^r\ 109^\circ 2' 2''.52\ T \\
&\quad - 37''.17\ T^2 - 0''.045\ T^3 \\
\text{Longitude of node} &= 259^\circ 10' 59''.79 \\
&\quad - 5^r\ 134^\circ 8' 31''.23\ T \\
&\quad + 7''.48\ T^2 + 0''.008\ T^3
\end{aligned}$$

Eccentricity ·054900489, corresponds to the coefficient 22639″·550 in the principal elliptic term; and sine of half the inclination ·044886967, corresponds to the coefficient 18461″·400 in the principal term in latitude.

The following are all the periodic terms in the moon's longitude as given in Brown's Tables with a coefficient over 212″. The parallactic term is added because of the attention it has attracted. The largest of the planetary terms, due to Venus, has a coefficient of 14″·27 and a period of 273 years. The next largest planetary terms are two or three of the order of 1″. The planetary terms usually have periods of about a month or a few years. The notation is as follows: l, l' are the mean anomalies of the moon and sun, D the excess of the moon's mean longitude over the sun's, F the argument of latitude.

$$\left.\begin{array}{l} +22639''.500 \sin l \\ +\quad 769.016 \sin 2l \end{array}\right\} \quad \text{Largest terms in equation of centre.}$$

$-\ 4586.426 \sin(l-2D)$	Evection.
$-\ 125.154 \sin D$	Parallactic inequality.
$+\ 2369.902 \sin 2D$	Variation.
$-\ 668.111 \sin l'$	Annual equation.
$-\ 411.608 \sin 2F$	Reduction to ecliptic.

In compiling the constants which could be derived directly from observation or by theory from other astronomical constants, the latter method generally has been followed. The term $7''\cdot 14\ T^2$ in the mean longitude was derived from pure theory, but it was known to be too small to fit ancient eclipse observations. The existence of a secular term in the moon's motion had been discovered by Halley. No explanation could then be given as to its origin. Lunar theory then took no account of planetary perturbations and gave no inequality in the moon's motion with a period exceeding 18·6 years. The first explanation of the secular term was given by Laplace who, from the secular change in the earth's orbit, computed a secular term with a coefficient of 10″ in the moon's motion. This agreed with the results derived from ancient eclipses. Laplace's immediate successors, amongst whom were Hansen, Plana and Pontécoulant, found a larger value, Hansen obtaining the value 12″·5. This value was found by himself and Airy to represent fairly well several ancient eclipses. But in 1853 Adams showed that these calculations were only a rough first approximation and that the rigorous theoretical value was only half as large. For some time there was considerable controversy on the subject but finally Adams's result was fully confirmed by Delaunay. The question then arose again as to the reason for the difference between observation and theory. It was pointed out independently by W. Ferrel in 1856 and a few years later by Delaunay that the attraction of the moon on the tidal wave must produce a frictional force tending to slow down the earth and apparently to accelerate the moon.

It will be seen that Brown has introduced one empirical term with a period of about 260 years into his tables in order to make them fit the observations from 1750 onwards more accurately than they otherwise would. When this is done there still remain residuals amounting to ±4″. These cannot be satisfied by one additional periodic term, but they can be satisfied very closely by two periodic terms in a variety of ways. In the *Monthly Notices* of the Royal Astronomical Society (vol. lxxxiii., p. 359) Sir Frank Dyson and Dr. A. C. D. Crommelin have analysed the residuals and found terms with coefficients of 3″·09 and 1″·66 and periods of about 70 years and 59 years respectively. It is not supposed, however, that these periodic terms will succeed in predicting accurately the moon's motion in the future.

It thus appears that the gravitational theory does not exactly explain the moon's motion. Searches for inequalities of long period produced by the action of planets have been carried out very thoroughly. It is now believed that the cause of the difference between prediction and observation lies in a variation of the earth's rate of rotation. If the earth rotates more slowly, the moon appears to go faster. Careful comparison of the observed and predicted positions of the other bodies in the solar system seem to indicate similar irregularities. The cause of a variable rotation of the earth has not yet been cleared up. If due to the action of the moon it will affect the mean motion of the moon so that other bodies in the solar system will not show the same proportional change as the moon; if due to a change in the earth's moment of inertia all bodies will show the same proportional change.

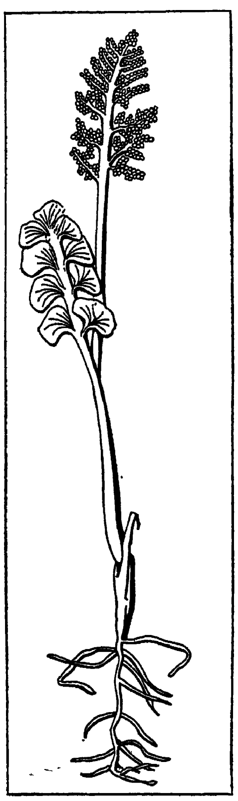
MOONSEED, in botany, a common name for *Menispermum* (family Menispermaceae), a genus of climbing deciduous shrubs, containing one species in North America and another in Eastern Asia. The former, the Canada moonseed (*M. canadense*), found from Quebec to Manitoba and southward to Georgia and Arkansas, is a handsome plant, with large reniform peltate leaves and yellowish flowers borne in profusion on long pendulous racemes.

MOONSTONE, a variety of orthoclase (*q.v.*) exhibiting a bluish-white or milky opalescence, whence its value as a gem stone. This optical phenomenon is probably connected with a perthitic intergrowth, the colours being interference colours from the enclosed lamellae of albite. The reflecting planes are submicroscopic and crystallographically near $\bar{8}01$ to $\bar{6}01$. Nearly all the moonstone of commerce comes from Ceylon, principally from the Dumbara district, occurring both in acid granulites and pegmatites and in gem gravels. X-ray analysis of a Ceylon moonstone ($Or_{73.5}Ab_{23.9}An_{2.6}$) shows that the schillerization is to be ascribed to the existence of an heterogeneous crystal structure on a minute scale. The system of double spots observable at ordinary temperatures in Laue photographs indicate an intergrowth of two space lattices. With rise of temperature these are seen gradually to approach and become coincident at 1060°, indicating that albite has been reabsorbed in solid solution in the orthoclase. (C. E. T.)



FROM STRASBURGER, "LEHRBUCH DER BOTANIK" (GUSTAV FISCHER)

MOONWORT (BOTRYCHIUM LUNARIA), A SMALL FERN HAVING THE SPORANGIA ARRANGED IN SMALL CRESTED CLUSTERS, WHICH FORM A LONG, LOOSE SPIKE

MOONWORT or **MOON-FERN,** in botany, the popular name of a small fern (*Botrychium Lunaria*), belonging to the family Ophioglossaceae. (*See* FERNS.) It has a tuberous rootstock and a stout fleshy glabrous frond 3 to 6 in. long, with a sterile and fertile portion; the former bears several pairs of close-set, semi-circular or moon-shaped pinnae, the latter is pinnately branched and covered, on the face opposed to the sterile portion, with small globose spore-cases which burst transversely. It is a widely distributed plant in the north and south temperate and cold zones, and is found in pastures and grassy banks in Great Britain and largely throughout northern North America, from Newfoundland to Alaska southward to Connecticut, Michigan, Colorado and British Columbia.

MOORCROFT, WILLIAM (*c.* 1770–1825), English traveller, was born in Lancashire, about 1770, and practised in London as a veterinary surgeon. He became inspector of the Bengal stud of the East India company in 1808. In this capacity he undertook a journey into Central Asia to obtain a stock of Turkoman horses. With Captain William Hearsey he left Josimath, well within the mountains, on May 26, 1812. Crossing the frontier pass of Niti, they struck the main upper branch of the Indus near its source, and on Aug. 5 arrived at the sacred lake of Manasarowar. Returning by Bhutan, he was detained some time by the Ghurkas, and reached Calcutta in November. Moorcroft set out on a second journey in Oct. 1819. On Aug. 14 the source of the Beas (Hyphasis) was discovered, and subsequently that of the Chenab. Leh, the capital of Ladakh, was reached on Sept. 24, and a commercial treaty was concluded with the Government of Ladakh, by which the whole of Central Asia was virtually opened to British trade. Kashmir was reached on Nov. 3, 1822, Jalalabad on June 24, 1824, Kabul on June 20, and Bokhara on Feb. 25, 1825. At Andkhui, in Afghan Turkestan, Moorcroft was seized with fever, of which he died on Aug. 27, 1825, his companion, George Trebeck, surviving him only a few days. But according to the Abbé Huc, Moorcroft reached Lhasa in 1826, and lived there 12 years, being assassinated on his way back to India in 1838. In 1841 Moorcroft's papers were obtained by the Asiatic Society, and published, under the editorship of H. H. Wilson, under the title of *Travels in the Himalayan Provinces of Hindustan and the Punjāb, in Ladakh and Kashmir, in Peshawur, Kabul, Kunduz and Bokhara, from 1819 to 1825.*

See Graham Sandberg, *The Exploraton of Tibet* (1904).

MOORE, ALBERT JOSEPH (1841–1893), English decorative painter, was born at York on Sept. 4, 1841. He was the youngest son of William Moore, of York, a painter of portraits and landscape, three of whose sons John Collingham Moore, Henry Moore, R.A. and Albert were artists. Albert studied under his father and he was a student in the Royal Academy schools for a few months. From 1858 to 1870, he executed decorative work of various kinds, and painted, in 1863, a series of wall decorations at Coombe abbey, the seat of the earl of Craven; in 1865 and 1866 some elaborate compositions: "The Last Supper" and "The Feeding of the Five Thousand" on the chancel walls of the church of St. Alban's, Rochdale; and in 1868 "A Greek Play," an important panel in tempera for the proscenium of the Queen's theatre in Long Acre. His first large canvas, "Elijah's Sacrifice," was completed in Rome at the beginning of 1863. A still larger picture, "The Shunamite relating the Glories of King Solomon to her Maidens," was exhibited in 1866. He died in London on Sept. 25, 1893. Several of his pictures are now in public collections; among the chief are "Blossoms," in the National Gallery of British Art; "A Summer Night" in the Liverpool Corporation Gallery; "Dreamers" in the Birmingham Corporation Gallery; and a watercolour, "The Open Book," in the Victoria and Albert Museum, South Kensington. Artistically he lived in a world of his own creation, a place peopled with robust types of humanity of Greek mould, and gay with bright-coloured draperies and brilliant-hued flowers.

See A. L. Baldry *Albert Moore* (1894).

MOORE, EDWARD (1712–1757), English dramatist and miscellaneous writer, the son of a dissenting minister, was born at Abingdon, Berkshire, on March 22, 1712. He was the author of the domestic tragedy of *The Gamester,* originally produced in 1753 with Garrick in the leading character of Beverley the gambler. He produced clever imitations of Gay and Gray, and with the assistance of George, 1st Lord Lyttelton, Lord Chesterfield and Horace Walpole, conducted *The World* (1753–57), a weekly periodical

on the model of the *Rambler*. Moore collected his poems under the title of *Poems, Fables and Plays* in 1756. He died in Lambeth on March 1, 1757. His *Dramatic Works* were published in 1788.

MOORE, GEORGE (1852–), novelist, eldest son of George Henry Moore, M.P. for Mayo, and his wife Mary Blake, was born at Moore Hall, Co. Mayo, on Feb. 24, 1852. He was at school at Escott, but, like many other great artists, did not take kindly or long to formal education. At the age of 18 he had already decided that art in some form or another was his vocation, and in the year 1870, on the death of his father, he entered the art schools at Paris. Though he was not destined to become a painter, those early years left a permanent mark on his artistic consciousness. Not only did he acquire that penetrating knowledge of pictures which has always distinguished him, but he learned both from the study of line, and from the brilliant painters and writers who became his friends, that relentless integrity of style, which gives each of his paragraphs something of the copper certainty of an etching. While in Paris and while still seeking for his medium he attempted poetry in *Flowers of Passion* (1878), and *Pagan Poems* (1882). Here again, though verse was not to be his method of expression, he still further prepared himself for his relentless economy of manner, more often found in poetry than prose.

Gradually, however, his true bent began to reveal itself, and he returned to England with the avowed intention of liberating English fiction from its Victorian shackles. *A Mummer's Wife* (1885) was in its way as startling a challenge to the contemporary novel as had been the first volume of "Poems and Ballads" to the poetry of its time. Moore took his place immediately as a rebel with a torch, not of an incendiary, but of a new luminary.

In his next considerable work *Confessions of a Young Man* (1888, latest ed. 1908), he took the first step on the path which was to lead to *Avowals* (1919 and 1926), *Hail and Farewell* (3 vols., 1911–14) and *Conversations in Ebury Street* (1924), no less than the gift of a new form to English prose. He turned from that to the three great novels of his prime: *Esther Waters* (1894), *Evelyn Innes* (1898), and *Sister Teresa* (1901). In these with quiet certainty he established the claim he had made in *A Mummer's Wife*. He believed that he had transplanted the French "philosophical" novel. What he had in fact done was to restore the Fielding tradition. He had given back honesty and clarity of vision, and an English almost flawless in its severe simplicity.

He had in the meantime also continued to express his artistic gospel in critical articles which were collected and published in 1891 and 1893 respectively. But the next landmark in his life was the return to Ireland in 1901, a return dictated in part by his detestation of the Boer War. He remained in Ireland until 1910, and though that period was not immediately productive (the only books in that time being *The Untilled Field* (1903), *The Lake* (1905) and *Memoirs of my Dead Life* (1905) it renewed his artistic youth. Imemdiately on his return to London he began the publication of *Hail and Farewell*—those entrancing dialogues which are regarded (wrongly) in certain quarters as his masterpiece. They are not that, but they would have been a masterpiece for anyone but the author of *The Brook Kerith* (1916, 7th revised ed. 1927) and *Heloise and Abelard* (1921). What turned Moore's mind to the gospel story as a subject for treatment is not clear, but at any rate in order to prepare himself for no less a task than re-creating the story of Jesus he visited Palestine. A record of that pilgrimage almost in his own words may be found in *Dialogues and Monologues* (Humbert Wolfe). The result of the journey was *The Brook Kerith* which, with *Heloise and Abelard,* touches a point of almost flawless artistry and nobility that has rarely been reached before in the history of English prose. In both these books he has reconstructed a period, and though to say so is almost hyperbole, in neither is his genius unworthy of its subject. Below these peaks, there were lesser though charming eminences in 1918 with *A Story-Teller's Holiday,* in 1924 with a version of *Daphnis and Chloe,* and in 1926 with an Irish story of the Middle Ages *Ulick and Soracha.* All these, like a note-book of Rembrandt, are full of convincing glimpses of the master.

Having tried painting, poetry, dialogue and the novel, he was not content till he had also attempted the drama. *The Coming of Gabrielle* (1920) was produced, but it was not till 1928, with *The Making of an Immortal* that he had a success in the theatre.

(H. Wo.)

BIBLIOGRAPHY.—His other works are: *A Modern Lover* (1883); *A Drama in Muslin* (1886); *A Mere Accident* (1887, "John Norton," in *Celibates* is a re-writing of this book); *Parnell and his Island* (1887); *Spring Days* (1888); *Mike Fletcher* (1889); *Vain Fortune* (1890); *Impressions and Opinions* (1891); *The Strike at Arlingford* (1893, a play); *Modern Painting* (1893); *Celibates* (1895); *The Bending of the Bough* (1900, a comedy); *Reminiscences of the Impressionist Painters* (1906); *Elizabeth Cooper* (1913, a comedy); *Lewis Seymour and Some Women* (1917. Re-writing of *A Modern Lover*); *The Pastoral Loves of Daphnis and Chloe* (done into English by George Moore, 1924. Later ed., 1927); *see* Susan L. Mitchell, *George Moore* (1916); I. A. Williams, *Bibliography of the Works of George Moore* (1921); J. Freeman, *Portrait of George Moore* (1922).

MOORE, GEORGE FOOT (1851–), American biblical scholar, was born in West Chester, Pa., Oct. 15, 1851. He graduated at Yale College in 1872 and at Union Theological seminary in 1877. In 1878 he was ordained and until 1883 was pastor of the Putnam Presbyterian church, Zanesville, Ohio. He was Hitchcock professor of the Hebrew language and literature in Andover Theological seminary in 1883–1902. In 1902 he became professor of theology and in 1904 professor of the history of religion at Harvard university. His chief critical work dealt with the *Hexateuch,* and more particularly the *Book of Judges* (commentary, 1895; text, translation and notes, 1898; text with critical notes, 1900). He was also the author of *The Literature of the Old Testament* (1913), *History of Religions* (2 vol., 1913–19), *Metempsychosis* (1914) and *Judaism in the First Centuries of the Christian Era* (2 vol., 1927).

MOORE, HENRY (1831–1895), English painter, the ninth son of William Moore, of York, and brother of Albert Joseph Moore, was born in York on March 7, 1831. His artistic education was supervised by his father; he attended the York school of design, and, for a short time the Royal Academy schools. He first exhibited at the Academy in 1853, and was a constant contributor to its exhibitions till his death. At the outset of his career he occupied himself mostly with landscapes and paintings of animals, executed with extraordinary detail in imitation of the prevailing taste of the Pre-Raphaelite Brotherhood; but in 1857, while on a visit to the West of England, he made his first attempts as a sea-painter. His success was immediate, and it had the effect of diverting him almost entirely from landscapes.

Among his most important canvases must be reckoned, "The Newhaven Packet" (bought by the Birmingham Corporation) and "Catspaws off the Land" (bought by the Chantrey Fund trustees) in 1885, "Mount's Bay" (bought by the Manchester Corporation). He was elected A.R.A. in 1885, and R.A. in 1893. He died at Margate on June 22, 1895. He had a rare understanding of wave-form and colour and the subtleties of atmospheric effect.

MOORE, SIR JOHN (1761–1809), British general, the son of John Moore, was born at Glasgow on Nov. 13, 1761. By the duke of Hamilton's influence he obtained an ensigncy in the 51st foot (1776), learned his drill at Minorca, and in 1778 was appointed captain-lieutenant in a new regiment raised by Hamilton for service in the American War. Moore remained in America to the peace of 1783, after which the Hamilton regiment was disbanded. In 1784 he was returned by the Hamilton interest as member of parliament for the united boroughs of Lanark, Selkirk, Peebles and Linlithgow. In parliament, though he never spoke, he seems to have taken his duties very seriously, and to have preserved an independent position, in which he won the friendship of Pitt and the respect of Burke, and (more important still) the friendship of the duke of York. In 1787 he became major in the 60th (now King's Royal Rifles), but in the following year he was transferred to his old corps, the 51st. In 1792 Moore sailed with his corps to the Mediterranean. He was too late to assist at Toulon, but was engaged throughout the operations in Corsica, and won particular distinction at the taking of Calvi, where he was wounded. Soon after this he became adjutant-general to Sir Charles Stuart, with whom he formed a close friendship. After the expulsion of the French Moore became

very intimate with many of the leading Corsican patriots, which intimacy was so obnoxious to Sir Gilbert Elliot (later Lord Minto) that Moore was eventually ordered to leave the island in forty-eight hours, though Elliot wrote in warm terms of his ability. Pitt and the duke of York thought still more highly of Colonel Moore, who was soon sent out to the West Indies in the local rank of brigadier-general. Here he came under the command of Sir Ralph Abercromby, whose most valued adviser and subordinate Moore soon became. In the Santa Lucia expedition he won further distinction by his conduct at the capture of La Vigie and Morne Fortuné, and when Sir Ralph left the island he appointed Moore governor and military commander. In 1798 he accompanied Abercromby to Ireland as a major-general, and during the rebellion was actively engaged in command of a corps in the south, defeating a large force of the Irish, and saving Wexford from destruction after the battle of Vinegar Hill (June 21). His services were in universal request, and Abercromby had him appointed to the command of a brigade destined for the expedition to Holland. At the action of Egmont-op-Zee, on the 2nd of October 1799, his brigade lost very heavily, and he himself was wounded for the fourth time, on this occasion severely. On his return from Holland he was made colonel of the 52nd regiment, with which he was connected for the rest of his career, and which he made one of the finest regiments in Europe.

Throughout the Egyptian expedition he commanded the reserve. The 28th and 42nd regiments in this corps gained great distinction at the battle of Alexandria, where Moore himself was again wounded. He returned to duty, however, before the surrender of the French forces to General Hutchinson, and added so much to his reputation by his conduct in this brilliant campaign that after the short peace came to an end he was appointed to command the force assembled at Shorncliffe camp (1803) as a part of the army intended to meet the projected invasion of Napoleon. Here were trained some of the best regiments of the service, amongst others the 43rd, 52nd and 95th Rifles, the regiments which afterwards formed the famous "Light Division" and won in the Peninsula an unsurpassed reputation, not only for the skilful performance of the duties of light troops, but also for invincible steadiness in the line of battle. These corps (now represented in the army by the 1st and 2nd battalions of the Oxfordshire Light Infantry and the Rifle Brigade) bore the impress of Moore's training for thirty years and more, and as early as 1804, on account of the "superior state" of the 52nd, the king granted the officers exceptional promotion (August 29, 1804).

While at Shorncliffe he renewed his intimacy with Pitt, who was then residing at Walmer Castle, and his close friendship with Lady Hester Stanhope led to the erroneous belief that he was betrothed to her. On his return to office Pitt caused Moore to be made a Knight of the Bath, and about the same time came his promotion to the rank of lieutenant-general. Fox, when he succeeded to office, showed the same appreciation of Moore, and in 1806 sent him to the Mediterranean as second-in-command to his brother, General H. E. Fox. In the various minor expeditions of the time Moore had a share, at first as a subordinate, but soon, when Fox went home on account of ill-health, as commander-in-chief of the British army employed in the Mediterranean.

In 1808 Moore was ordered to the Baltic, to assist Gustavus IV., king of Sweden, against Russia, France and Denmark. The conduct of the king, who went so far as to place Sir John Moore under arrest when he refused to acquiesce in his plans, ruined any chance of successful co-operation, and the English general returned home, making his escape in disguise. He was at once ordered to proceed with his division to Portugal, where he was to be under the command of Sir Hew Dalrymple and Sir Harry Burrard. To Moore, as a general of European reputation, who had held a chief command, the appointment of two senior officers to be over him appeared as a bitter insult, though his resentment did not divert him from his duty. He met his reward, for when, in the excitement caused by the convention of Cintra, Dalrymple and Burrard were ordered home, Moore was left in command of the largest British army that had been employed since the commencement of the war.

It was not long before the Spaniards summoned Sir John Moore's army to assist them against the advance of Napoleon, and the troops were marched into Spain, Salamanca being their rendezvous. There Moore remained for a month, calling up Sir David Baird's corps from Corunna to assist him. Soon, however, the overwhelming success of the emperor's attack threatened to isolate Moore, and it was then that he formed the magnificent resolution of marching northwards against the French line of retreat. The bold and skilful operations which followed this step will be found outlined in the article Peninsular War. Moore's advance paralysed the emperor's victorious armies. Napoleon himself turned against the British army, which was soon in grave danger, but Spain was saved. Under these circumstances took place the famous retreat on Corunna. The indiscipline of a large proportion of the troops made it painful and almost disastrous, but the reserve under Edward Paget, in which served Moore's old Shorncliffe regiments, covered itself with glory in the ceaseless rearguard fighting which marked every step of the retreat. The march ended with the glorious battle of Corunna (Jan. 16, 1809), where, early in the day, Sir John Moore received his death wound. He would not suffer his sword to be unbuckled, though the hilt galled his wound, and so he was borne from the field. His last hours were cheered by the knowledge of victory, and his only care was to recommend his friends, and those who had distinguished themselves, to the notice of the government. He died with the name of Lady Hester Stanhope on his lips. By his own wish he was buried, before dawn on the 17th, in the ramparts of Corunna. The poem by the Rev. Charles Wolfe, "The Burial of Sir John Moore," became one of the most popular in the language.

For many years controversy, largely political, raged over the events of the Corunna campaign, and only at a later period has any examination of Sir John Moore's merits and services been made in a dispassionate spirit. Mistakes were doubtless made in the retreat, but it is sufficient to accept Napoleon's view that they were probably inseparable from the difficulties with which Moore was surrounded. His greatest claim to renown is, however, independent of his conduct of armies in the field. He was the finest trainer of men that the British army has ever known. He had the true gift of the great man, judgment of character. While Wellington, whose work would have been vain but for Moore's achievements, perpetually complained of his officers and formed no school, Moore's name is associated with the career of all who made their mark. The history of the Light Division is sufficient in itself to indicate the results of Moore's training on the rank and file. In opposition to the majority, who regarded the lash and the gallows as the source of discipline, he sought always and by every means to develop the moral qualities no less than the physical. Of the senior officers Hope, Graham, Edward Paget, Hill and Craufurd all felt and submitted to his ascendancy. The flower of the younger generation, Colborne, Hardinge and the Napiers, though they gained their laurels under Wellington and in chief command, were ever proud to call themselves "Sir John Moore's men."

See, besides the works mentioned in the article Peninsular War, J. C. Moore, *Life of Sir John Moore* (1834); *The Diary of Sir John Moore* (ed. by Sir J. F. Maurice, 1904) and the Records of the 52nd (Oxfordshire Light Infantry).

MOORE, JOHN (1729–1802), Scottish physician and writer, was born at Stirling in 1729, the son of a clergyman. After taking his medical degree at Glasgow, he served with the army in Flanders, then proceeded to London to continue his studies, and eventually to Paris, where he was attached to the household of the British ambassador. His novel *Zeluco* (1789), a close analysis of the motives of a selfish profligate, produced a great impression at the time, and indirectly, through the poetry of Byron, has left an abiding mark on literature. Byron said that he intended Childe Harold to be "a poetical Zeluco." Moore's *Journal during a Residence in France* (1793) is the careful record of an eye-witness of the Revolution and is frequently referred to by Carlyle. He died in London on Jan. 21, 1802, leaving five sons, the eldest of whom was General Sir John Moore. James Moore (1763–1834) who wrote Sir John's *Life,* was also an author of medical works.

MOORE, JOHN BASSETT (1860–), American jurist, was born at Smyrna, Del., on Dec. 3, 1860. He graduated at the University of Virginia in 1880, studied law in an office in Wilmington, Del., and was admitted to the Delaware bar in 1883. Two years later he entered the Department of State as a law clerk, and in 1886 was appointed third assistant secretary of State. He was secretary to the conference on Samoan affairs in 1887 and U.S. secretary at the conference on North Atlantic fisheries, 1887–88. He was appointed professor of international law and diplomacy at Columbia university, 1891, frequently being granted leave of absence to accept appointments in the national interest. On the outbreak of the war with Spain in 1898 he was appointed assistant secretary of State, and he acted as secretary and counsel to the U.S. peace commissioners at Paris at the close of the war. Among the later official positions which he filled were those of U.S. agent before the United States and Dominican Arbitration Tribunal, 1904; U.S. delegate to the fourth International American conference at Buenos Aires, 1910; special U.S. plenipotentiary to the Chilean Centenary, 1910; U.S. delegate to the International commission of jurists, Rio de Janeiro, 1912; counsellor to the Department of State, 1913–14; a member of the Permanent Court of Arbitration at The Hague, 1913; U.S. delegate to the Pan-American financial congress, 1915. He was appointed in 1921 a judge of the Permanent Court of International Justice from which he resigned on April 29, 1928, to edit a comprehensive historical collection of treaties. He was also U.S. delegate and chairman of the International Conference on rules for aircraft and radio in time of war held at The Hague, 1922–23.

Moore's publications include *Extradition and Interstate Rendition* (1891); *History and Digest of International Arbitrations* (1898); *American Diplomacy: Its Spirit and Achievements* (1905); *Digest of International Law* (1906); *Four Phases of American Development* (1912); *Principles of American Diplomacy* (1918); *International Law and Some Current Illusions* (1924); and *The Permanent Court of International Justice,* a pamphlet (1924).

MOORE, THOMAS (1779–1852), Irish poet, was born in Dublin on May 28, 1779. His father was John Moore, a prosperous grocer and wine merchant, and his mother's maiden name was Anastasia Codd. In 1793 Tom Moore's name first appeared in print, as a contributor of some verses "To Zelia," to a Dublin periodical, the *Anthologia Hibernica.* In the same year Roman Catholic students began to be admitted to Trinity college, Dublin, and in 1794 Moore's name was entered on the books, curiously enough, as a Protestant. At Trinity he made friends with Robert Emmet, and was nearly dragged into the plots of the United Irishmen. The events of 1798 and the execution of Emmet in 1803 made a deep impression on him. The words of Emmet's address to his judges, asking the charity of silence—"Let no man write my epitaph"—are enshrined by Moore in one of his lyrics, "Oh, breathe not his name!" (*Irish Melodies,* 1808.) The next song in the same collection—"When he who adores thee"—also owes its inspiration to Emmet's fate, and the conscientious orientalism of *Lalla Rookh* does not conceal the pre-occupation of the writer with the United Irishmen when he writes of "The Fire Worshippers," and with Emmet and Sarah Curran when he describes the loves of Hafed and Hinda, especially in the well-known song, "She is far from the Land where her young Hero sleeps." In 1798 Moore graduated, and in the next year left for England to keep his terms at the Middle Temple.

He was a social success in London. He had brought with him from Ireland a translation of the *Odes of Anacreon,* and the prince of Wales accepted its dedication. It was issued in 1800 with notes and a list of distinguished subscribers. Moore's social successes involved him in expenses far beyond his means. His publisher had advanced him money, and he resolved to pay his debt by the anonymous publication of his juvenile poems, *The Poetical Works of the Late Thomas Little, Esq.* (1801), a collection of love poems which Moore afterwards regretted. Through Lord Moira's influence he was, in 1803, appointed registrar of the admiralty prize-court at Bermuda. But he soon tired of the monotonous life, and in 1804, after appointing a deputy, returned to England by way of the United States and Canada. In 1806 he published *Epistles, Odes and other Poems,* chiefly dealing with his impressions of travel. The volume contained the "Canadian Boat Song" ("Faintly as tolls the evening chime"), and some love poems of the same kind as those connected with the name of "Mr. Little."

The success of the satirical epistles in the 1806 volume encouraged Moore to produce further work of a similar kind, *Corruption and Intolerance, Two Poems* (1808), and *The Sceptic: a Philosophical Satire* (1809), but the heroic couplet and the manner of Pope did not suit his talents. At the end of 1806 he went to Dublin, and, with the exception of about six months in 1807 spent at Donington Park, the next three years were spent in Ireland. Here he met Miss Elizabeth Dyke, an actress, who became his wife in March 1811. They lived at first in London, but soon removed into the country, to Kegworth, near Lord Moira's seat, and then to Mayfield Cottage, near Ashbourne, Derbyshire. Moore had to spend much of his time in London, for the popularity of his songs led to an agreement with his publisher to increase the success of these by singing them himself at great houses. The inception of his *Irish Melodies* dates from 1807, and many of the best were written during the three years of his Irish visit. He had already published separate songs, some of them set to music of his own, when William Power suggested to him in 1807 the task of fitting words to a series of Irish airs supplied by Sir John Stevenson. He could not have found a task more exactly suited to his powers, and for a quarter of a century he enjoyed a regular income of £500 a year from Power for writing words to music. The first number of the *Irish Melodies* appeared in 1808, and contained some of his best and most popular work. The rest appeared between 1808 and 1834. In 1816 Stevenson and Moore published *Sacred Songs,* followed by a second number in 1824. The first number of *National Airs* (Melodies from other Nations) appeared in 1818, and was followed by others in 1820, 1822, 1826 and 1827.

After 1812 he broke ground in a new field—political squib-writings. His first butt was the prince regent, once his friend and patron, whose foibles, fatness, love for cutlets and curaçao, for aged mistresses and practical jokes, were ridiculed with the lightest of clever hands. His earlier political poems appeared in the *Morning Chronicle,* but in 1813 he published a thin volume of *Intercepted Letters: The Twopenny Post Bag.* Other volumes of squibs, most of which passed through several editions, followed: *The World at Westminster* (1816), *The Fudge Family in Paris* (1818), *The Journal of a Member of the Pococurante Society* (1820), *Fables for the Holy Alliance* (1823), *Odes on Cash, Corn, Catholics and other Matters* (1828), *The Fudge Family in England* (1835). The only failure among his satirical writings was *Tom Crib's Memorial to Congress* (1819) for which he had made an elaborate study of thieves' argot.

In 1814 he contracted with the firm of Longmans, for 3,000 guineas, to supply a metrical romance on an Eastern subject. Moore retired to a cottage in the neighbourhood of Donington Park, where with the help of Lord Moira's library he read himself slowly into familiarity with Eastern scenery and manners. But he was forestalled by Byron in *The Giaour* and again in *The Bride of Abydos.* The publication of *Lalla Rookh* was deferred until 1817. It was an immediate success. After the completion of *Lalla Rookh,* Moore removed with his family to Sloperton Cottage, Wiltshire, where he was close to Bowood, Lord Lansdowne's country seat. Moore's plans were interrupted by the embezzlement of some £6,000 by the deputy he had left in Bermuda, for whose default he was fully liable. To avoid a debtors' prison Moore retired to the Continent. He visited Byron in Italy, and in Oct. 1819 received from him the first part of the *Memoirs.* The continuation was sent to Moore in Paris the next year, with Byron's suggestion that the reversion of the ms. should be sold. Moore did not remain long in Italy, but made his home in Paris, where he was joined by his wife and children. He was not able to return to England until 1822, when the Bermuda affair was compromised by a payment through Longmans of £1,000.

During his exile he had written another oriental poem, *The Loves of the Angels* (1822), which was hardly less popular than *Lalla Rookh.* He became a contributor of satirical verse to *The*

Times, the connexion lasting until 1827. He now wrote his *Memoirs of the Life of Sheridan,* first contemplated in 1814, which appeared, after some delay, in 1825. The *Memoirs of Captain Rock* (1824), in which he gives a humorous but convincing account of English misgovernment in Ireland, was the result of a tour with Lord Lansdowne in western Ireland. His prose tale, *The Epicurean,* appeared in 1827, and the *Legendary Ballads* in 1830. In 1831 he completed his *Life and Death of Lord Edward Fitzgerald,* probably his best piece of prose work.

The death of Byron in 1824 raised the question of the publication of his *Memoirs.* Moore had parted with them in 1821 to John Murray for £2,000. After they had come into Murray's possession, Moore began to have doubts about the propriety of publishing them, and an arrangement was therefore made that the £2,000 should be regarded as a loan, to be repaid during Byron's lifetime, and that the ms. should be retained as a security. When Byron died the *Memoirs* were still unredeemed, and the right of publication therefore rested with Murray. Moore now borrowed the money from Longmans and induced Murray to give up his claim. The money was paid, and, after a heated discussion with Byron's executors, the ms. was burnt. It was partly the pressure of the debt thus contracted, and partly the expressed wish of Byron, that induced Moore to undertake for Murray *The Letters and Journals of Lord Byron, with Notices of his Life* (1830).

In 1830 he undertook to write a *History of Ireland* which he left unfinished. After the death of his last child in 1845, Moore became a total wreck, but he lived until Feb. 25, 1852. He left sufficient provision for his wife in the *Diary* which he kept chiefly on her behalf.

His other works are, *A Letter to the Roman Catholics of Dublin* (1810); *A Melologue upon National Music* (1811); an operetta, *M.P. or The Blue Stocking* (1811); *A Set of Glees* (1827); *The Summer Fête* (1831); *Evenings in Greece* (1826–32); *Travels of an Irish Gentleman in Search of a Religion; Alciphron, a Poem* (1839).

See *Memoirs, Journal and Correspondence of Thomas Moore* (8 vols., 1853–56), ed. by Lord John Russell, which contains an immense quantity of biographical material; *Tom Moore's Diary* (1925); *The Poetical Works of Thomas Moore, Collected by Himself* (10 vols., 1840–42); also *Notes from the Letters of Thomas Moore to his Music Publisher, James Power* (1854); and *Prose and Verse, Humorous, Satirical and Sentimental by Thomas Moore, with suppressed passages from the memoirs of Lord Byron . . .* (1878), which includes Moore's contributions to the *Edinburgh Review* (1814–34). Among modern editions of Moore's *Poetical Works* may be mentioned that by Charles Kent (the Centenary ed., 1879), and that by W. M. Rossetti (1880). Memoirs of Moore are prefixed to these editions. There are many contemporary references to him, especially in the journals and letters of Byron. There is an excellent life, by Stephen Gwynn, *Thomas Moore* (1905), written for the "English Men of Letters Series."

MOORE, THOMAS STURGE (1870–), English poet, art critic and engraver, was born at Hastings, on March 4, 1870. Besides many collections of poetry he published studies of Altdorfer, Dürer, Correggio and others, and several volumes of essays.

His publications include: Poetry, *Vinedresser and other Poems* (1899), *Aphrodite against Artemis* (1901), *Absalom,* a play (1903), *The Little School* (1905, enlarged edition 1917), *Marianne* (1911), *The Sea is Kind* (1914), *Danaë* (1920), *Aforetime* (1920); Essays, *Art and Life* (1910), *Hark to these Three* (1915), *Some Soldier Poets* (1919), *Blind Thamyris,* a prose idyll (1920), *Judas* (1923).

MOORHEAD, a city of western Minnesota, U.S.A., on the Red River of the North, at an altitude of 907 ft., opposite Fargo (N.D.) and 250 m. N.W. of Minneapolis; the county seat of Clay county. It is on Federal highways 10N, 10S and 75 and the main lines of the Great Northern and the Northern Pacific railways. Pop. (1920) 5,720 (21% foreign-born white, largely from Norway, Sweden, Germany and Canada); 7,651 in 1930 by the Federal census. It is the seat of a State Teachers' college (established 1888) and of Concordia college (Norwegian Lutheran, 1891) which together increase the population by 1,000 students during 10 months of the year. Moorhead is a pleasant residential city, a general trading centre, and an important distribution point for potatoes, of which the county produced 4,000,000 bu. in 1926. There are several manufacturing industries, including a creamery which uses $3,000,000 worth of dairy and poultry products annually. Moorhead was founded in 1871 and was named after a member of the first board of directors of the Northern Pacific Railway. It was chartered as a city in 1881.

MOOR-HEN or Water-Hen, one of the *Rallidae* and a common bird throughout the Old World. One species, *Gallinula chloropus,* is about the size of a bantam hen, dark olive-brown above, iron-grey below, with white tail coverts which are conspicuous as it swims, and a scarlet frontlet in both sexes. It haunts rivers, streams, lakes and ponds, building a nest of flags, reeds, etc., on a clump of rushes, in or under a bush or on a tree, usually near the water, but occasionally some distance from it. The eggs, 7 to 11 in number, are dull buff with reddish spots. The bird swims well but in a jerky fashion, runs fast and, though taking wing with difficulty, is capable of prolonged and rapid flight. The American *G. galeata,* distinguishable by its larger frontal helm, is closely allied, and other species inhabit Africa, Asia and Australia. *G. nesiotis* of Tristan da Cunha has lost the power to fly. The purple water-hens or sultanas (*Porphyrio*) are an allied genus, species of which inhabit Europe, Africa, S. America and Australasia. The flightless *Notornis hochstetteri* of New Zealand and the purple gallinule or mud-hen (*Ionornis martinicus*) of S. and Central America and southern U.S.A. are other relatives.

MOORING MAST: *see* AERODROME.

MOORS (MAURES), a long-headed, fine-featured people of medium height with oval faces, hooked noses and slender, supple limbs, inhabiting Mauritania and the Northern Sudan, and descended from the Zenaga Berbers of southern Morocco who occupied Adrar and Tagant and later Hodh and Azaouad. In the 11th century they formed the Almoravide sect which conquered Morocco and Spain.

In the 16th century Kounta Arabs placed the southern tribes in subjection. Later, the Beni Hassan Arabs subjugated Tagant, Hodh and then the right bank of the Sénégal. Principal tribes in Mauritania are the Trarza, Brakna and Oulad Mbarck; in the Sudan, the Kounta, Berabich, Regeïbat, Mejdouf, Oulad Delim and Oulad Nassen. Fanatical Muslims, they obey Koranic law. Polygamy is rare, and divorce frequent; marriage is between members of the same caste. The following castes can be distinguished: (*a*) warriors or Hassane, descendants of the Arab invaders; (*b*) Marabout priests, commentators on the Koran, traders, doctors; (*c*) Zenaga, descendants of the early Berbers; (*d*) Harratine or liberated captives. They are nomads practising very little agriculture, and are held to be treacherous, thieves and redoubtable raiders.

See P. Marty, *L'Emirat des Trarzas* (1919); *Les Brakna* (1920); *Études sur l'Islam et les Tribus Maures* (1921).

MOOSE, the North American name of the elk (*q.v.*).

MOOSEJAW, a city and electoral division of Saskatchewan, Canada. Pop. (1931) 21,299. It is situated on a divisional point of the Canadian Pacific railway, about 400 miles W. of Winnipeg, and owes its importance chiefly to its railway connections. The principal industries include lumber and flour mills, iron works and the manufacture of agricultural implements. *See* SASKATCHEWAN.

MOOT, the common term for the assemblies of the hundred, borough, etc., in the history of early English institutions, and especially for the national assembly or council, the Witenagemot. The name survives in "moot hall," the term still applied to town-halls and council buildings in some English towns. From its meaning of assembly, the word was applied to a debate or discussion, in particular to the discussion of hypothetical cases by law students at the Inns of Court.

MOPLAH, a fanatical Mohammedan sect found in Malabar. They are believed to be descended from Arab immigrants who settled on the western coast of India and married local women, in the 9th century A.D. They are remarkable for the fanaticism displayed in attacks upon Hindus. The last rising was in 1925.

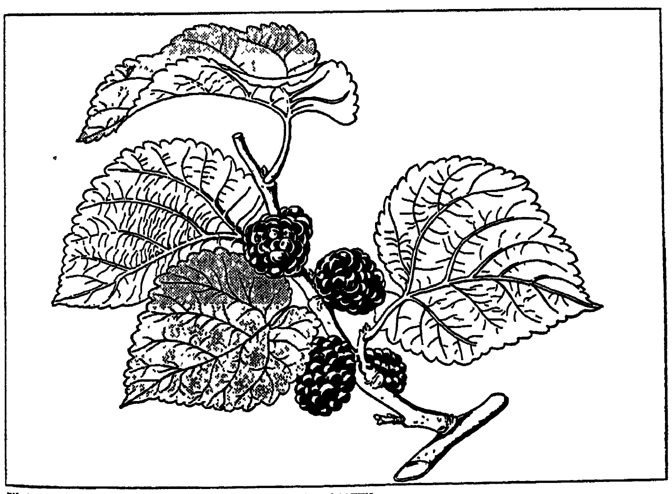
See *Tribes and Castes of Southern India* (1909).

MOPSUS, (1) Son of Ampyx (or Ampycus) and the nymph Chloris, a Lapith of Oechalia in Thessaly. He took part in the Calydonian boar hunt, and accompanied the Argonauts as their

prophet. He died from the bite of a serpent. He was afterwards worshipped as a hero and an oracle was consecrated to him. (2) Son of Rhacius (or Apollo) and Manto, daughter of Teiresias. Calchas is said to have died of chagrin because Mopsus outdid him in a contest of divination. Mopsus founded Mallus in Cilicia with the help of Amphilochus; he also is said to have built Colophon and his name is preserved in the place names Μόψου Ἑστία Μόψου Κρήνη. He was worshipped as a god by the Cilicians, and had two famous oracles at Colophon and Mallus.

MOQUEGUA, a maritime province of southern Peru, with the prerogatives of a department, bounded on north and east by the departments of Arequipa and Puno, south by Tacna Libre and west by the Pacific. Area 5,550 sq.m.; estimated population, (1920), 42,694. It includes the valley of the Moquegua river and the upper tributaries of the Tambo, the rest of the province consisting of barren *sierra* with great volcanic peaks and steep, narrow gorges, and the desert coast area. The vineyards and olive orchards of Moquegua, formerly famous, are giving way to cotton plantations. Other crops, maize, fruits and vegetables find local markets. Livestock is raised to a limited extent. Mineral resources are undeveloped. In fact, in spite of historical importance and great natural resources, the province is the most isolated and least developed of any on the coast. It possesses no system of roads except in the immediate vicinity of the capital, Moquegua. There is one railway which gives weekly service from Moquegua to its small though excellent port, Ilo, 63 m. distant, the most southerly of Peru. The capital, Moquegua, an Inca and colonial city (estimated pop. 5,680), in the valley of the Moquegua, 4,500 ft. above sea-level, a primitive town with excellent climate, has never recovered from its destruction by Chilean soldiers in 1881.

MORACEAE, in botany, a family of dicotyledons, belonging to the series *Urticales,* to which belongs also the nettle family (Urticaceae, *q.v.*). It contains about 55 genera with about 800 species, mostly trees or shrubs, widely distributed in the warmer parts of the earth. The largest genus, *Ficus* (the fig, *q.v.*), contains 800 species spread through tropical and sub-tropical regions, and includes the common fig of the Mediterranean region (*Ficus carica*), the banyan (*F. benghalensis*), and the india-rubber plant (*F. elastica*); many of the species are epiphytic, sometimes clinging so tightly round the host-plant with their roots as to strangle it.



BY COURTESY OF THE ROYAL HORTICULTURAL SOCIETY
BLACK MULBERRY (MORUS NIGRA), SHOWING BRANCH WITH FRUIT

Morus (mulberry, *q.v.*) contains ten species of trees or bushes in north temperate regions and in the mountains of the tropics. *Artocarpus,* including *A. incisa* (bread-fruit, *q.v.*), and *A. integrifolia* (jack-tree), has forty species, chiefly natives of the Indian Archipelago. The plants are rich in latex which may be very poisonous, as in *Antiaris toxicaria,* the Upas tree (*q.v.*) of Java, or sweet and nutritious as in *Brosimum Galactodendron,* the cow-tree (*q.v.*) of Venezuela. The latex often yields caoutchouc as in species of *Ficus* (*e.g., F. elastica*), *Cecropia* (*q.v.*), a tropical American genus with thirty to forty species, and others. In eastern United States the family is represented by *Morus* (mulberry) and one species of *Maclura* (osage orange), the latter being much planted for hedges. In the western United States (Rocky Mountain region) there are no native representatives of the family.

From the evidence of leaf-fossils, it is probable that the genus *Ficus* existed as far north as Greenland in the Cretaceous era and was generally distributed in North America and Europe in the Tertiary period up to Miocene times.

MORADABAD, a city and district of British India, in the Bareilly division of the United Provinces. The city (pop. 82,671 in 1921), on the right bank of the river Ramganga, was founded in 1625 by Rustam Khan, who built the fort which overhangs the river bank, and the fine Jama Masjid or great mosque (1631). The town has a special industry in ornamental brassware, sometimes plated with lac or tin, which is then engraved. Cotton weaving and printing is also carried on.

The DISTRICT OF MORADABAD lies east of the Ganges and west of the Rampur state. Area, 2,285 sq.m. It is traversed by the Ramganga and Sot. The eastern tract is submontane. The central portion consists of a level central plain descending at each end into the valleys of the Ramganga and Sot. The western section has a gentle slope towards the Ganges, with a rapid dip into the lowlands a few miles from the bank of the great river. In addition to Moradabad the principal towns are Amroha (*q.v.*), Sambhal (41,585) and Chaudausi (25,164).

For the early history of Moradabad *see* BAREILLY. It passed into the possession of the British in 1801. The population in 1921 was 1,198,653. Mohammedans are more numerous than in any other district of the province, forming more than one-third of the total population. Crops include wheat, rice, millet, pulse, sugar-cane and cotton.

MORAES, FRANCISCO DE (*c.* 1500–1572), Portuguese romance writer, was treasurer of the household to King John III., and he is first found in Paris in the suite of the Portuguese ambassador, D. Francisco de Noronha, who had gone there in 1540. He was a commander of the Order of Christ, and was called *O Palmeirim* on account of his authorship of the famous romance of chivalry, *Palmeirim de Inglaterra;* in 1572 he was assassinated at Evora. He appears to have written his book in France (perhaps in Paris) in 1544, dedicating it to the Infanta D. Maria, daughter of King Manoel, but the first extant Portuguese edition only came out in 1567. The *Palmeirim de Inglaterra* belongs to another branch of the same cycle as the *Amadis de Gaula;* the two romances are the best representatives of their class, and for their merits were spared from the *auto da fé* to which Cervantes condemned other romances of chivalry in *Don Quixote*. It has a well-marked plot, clearly drawn characters, and an admirable style, and has been reckoned a Portuguese classic from the time of its issue.

BIBLIOGRAPHY.—The *Palmerin of England,* by W. E. Purser (Dublin, 1904), contains an exhaustive study of the romance and the controversy concerning its authorship, with a sketch of the plot.

MORAINE, a term adopted from the French for the rocky material carried downwards by a glacier, and according to the position of the moraine on the glacier different names are applied to it. The *lateral* moraine occurs at the glacier side as a long mound, and when two glacial valleys converge into one valley two lateral moraines unite and form a *median* moraine in the resultant broader glacier. The material carried by the glacier is deposited where the glacier ends, and forms the *terminal* moraine, frequently in the form of a crescentic dam across the valley. The material pushed forward beneath the glacier is sometimes called the *ground* moraine. (*See* GLACIER.)

MORALE IN WAR: *see* ARMY, *Morale in War*.

MORALES, LUIS DE (*c.* 1509–1586), Spanish painter, called El Divino because of his emotional religious paintings, which appealed to the people. His favourite subjects, "Ecce Homo," "Pietà," "Christ at the Column," "Mater Dolorosa" were repeated many times and often copied. He was the first Spanish artist of pronounced national character, and one of the few Spanish painters who were summoned by Philip II. to help in the decoration of the Escorial; but his picture "Christ carrying the Cross" did not please the king, and was removed to the church of S. Jeronimo at Madrid. The story goes that the king

met the artist again at Badajoz in 1581, a few years before his death, and seeing that he was old and poor allowed him a pension. Morales' chief works are 20 panels with scenes from the life of Christ, painted for the church of Arrogo del Puerco (1563–68). One of his finest and most moving pictures is "Pietà" in the Academy at Madrid. The Hispanic Society in New York has three of his works. Others are at Dresden, London, Dublin, Paris.

MORALITY, PRIMITIVE. We know nothing of the beginnings of the moral life of man, nothing of the transition from animal behaviour to human conduct. In animal behaviour there is not a rudimentary morality but rather the material which, in human life, intelligence fashions into morality. The only source of knowledge available is the mind of the modern savage, with those relics of primitive ways of thought which survive in the folklore and superstitious practices of higher races. The basic needs which must be subserved if life is to endure are self-preservation and the preservation of the race. It is by food and the production and survival of offspring that these needs are satisfied, and round them the body of primitive morality is built up. Universally among primitive peoples there are tabus ("it is forbidden") in connection with food. As to the other great instinctive process, the preservation of the race, we find everywhere a close knit body of custom. Pregnancy, birth, puberty, menstruation, marriage, death, all are crises in which man comes into contact with the "sacred," all are bound up with the preservation of the race, so round them gathers a body of tabus and regulations.

Undoubtedly bravery is approved and cowardice condemned by primitive races; love is shown for spouse and children, and generosity is often considered a high social virtue. Again "oversexed" persons are regarded with a contempt which approaches moral reprobation, while in barter the whole system depends on the reliance to be placed on the good faith of both parties. But we find Society all-powerful, the individual wholly subordinate. Yet, in those early, hard days the assertion of man's individuality would only have procured his extinction. Life and the handing on of life were the vital interests of the individual as of society. "The individual, tended and cared for throughout his childhood, grows up accustomed to expect from others what he comes to find that they expect from him. So he comes to see himself as others see him when he is praised or blamed for acts that he has long been ready to approve or disapprove in them. In a word his self-consciousness becomes conscience: he seems to hear two voices within his breast, and one speaks with the authority of law: it is his 'tribal self'." (Ward, *Psychological Principles.*) If man is to live, he must so live that others may live also, thus he passes on himself moral judgment in the name of the community. But all the moral innovators down the ages have been those who, in some degree at least, have outgrown the "tribal self," primitive morality, and been inspired themselves and inspired others with an "Enthusiasm of humanity."

MORAL SENSE: *see* Ethics, History of.

MORAN, EDWARD (1829–1901), American artist, was born at Bolton, Lancashire, on Aug. 19, 1829. He emigrated with his family to America at the age of 15 and settled in Philadelphia, where after having followed his father's trade of weaver he became a pupil of James Hamilton and Paul Weber. In 1862 he became a pupil of the Royal Academy in London; he established a studio in New York in 1872, and for many years after 1877 lived in Paris. He was a painter of marine subjects, and examples of his work are in many prominent collections. Among his canvases are 13 historical paintings, intended to illustrate the marine history of America from the time of Leif Ericsson to the return of Admiral Dewey's fleet from the Philippines in 1899. He died in New York city on June 9, 1901. His sons (Edward) Percy Moran (b. 1862) and Léon Moran (b. 1864), and his brothers Peter Moran (b. 1842) and Thomas Moran (*q.v.*) also became prominent American artists.

MORAN, PATRICK FRANCIS (1830–1911), cardinal archbishop of Sydney, was born at Leighlinbridge, Ireland, on Sept. 16, 1830. He was educated in Rome, from the age of 12, at the Irish college of St. Agatha, where he later became principal (1856–66). He was ordained a priest on March 19, 1853. From 1866 to 1872 he was secretary to his uncle, Cardinal Cullen, archbishop of Dublin. In 1873 he became bishop of Ossory, and in 1884 archbishop of Sydney. He was consecrated cardinal at Rome in August 1885. He paid many visits to Rome, and as primate of Australia presided over the plenary councils of 1885, 1895 and 1905. He died on Aug. 16, 1911, at Manby Palace, Sydney. His uncompromising attitude on religious questions provoked much controversy, but he did good work in the educational sphere, and arranged for the building of many schools, as well as churches and hospitals. He was active in Australian politics, and a supporter of Australian federation.

His most important works are the *History of the Catholic Archbishops of Dublin* (Dublin, 1864) and *Spicilegium Ossoriense* (3 series, Dublin, 1874–84).

MORAN, THOMAS (1837–1926), American artist, was born at Bolton, Lancashire, on Jan. 12, 1837, and emigrated with his parents to America in 1844, the family settling in Philadelphia. After having been apprenticed for some years to a wood-engraver he studied under his brother Edward and under James Hamilton in Philadelphia, and later studied in London, Paris and Italy. In 1871 he accompanied Prof. F. V. Hayden's exploring expedition to the Yellowstone, and in 1873 he went down the Colorado with Major J. W. Powell's famous exploring party; and on these two trips he made sketches for two large pictures, "The Grand Cañon of the Yellowstone" and "Chasm of the Colorado River," both of which were bought by the U.S. Government and are now in the Capitol at Washington. He became a member of the National Academy of Design in 1884 and of the American Water Color Society. He died at Santa Barbara, Calif., on Aug. 26, 1926.

MORAND, PAUL (1888–), French novelist, was born on March 13, 1888. He studied law and political science, and joined the diplomatic service, serving as attaché in London, Rome and Paris. He was then appointed chief of section of the *service des oeuvres françaises a l'étranger.* Morand made a European reputation by a series of arresting stories of life in different parts of post-war Europe.

His best-known books are *Tendres stocks* (2nd ed. 1921); *Ouvert la Nuit* (26th ed. 1922); *Fermé la Nuit* (1923); *Lewis et Irène* (1924); *L'Europe Galante* (1925).

MORANT, SIR ROBERT LAURIE (1863–1920), British civil servant, was born at Hampstead on April 7, 1863. He was educated at Winchester and at New college, Oxford, and on leaving the university was for a few years a schoolmaster. Later he went to Siam as educational adviser, and was entrusted by King Chulalongkorn with preparing a scheme of education for the whole country. In a few years he returned to England, and after some experience of social work in the east end of London, was appointed in 1895 to assist in the direction of the office of special inquiries and reports in the board of education. He became private secretary to successive ministers, and on him devolved a great deal of the preparation of Balfour's Education Act of 1902. In 1903 he was appointed permanent secretary of the Board of Education. In this capacity he proved himself a most efficient administrator, and in 1907 he was created K.C.B. In 1912, on the introduction of the National Insurance bill, Morant was appointed chairman of the Insurance Commission, a position which led naturally to his appointment as secretary to the Ministry of Health on its formation in 1919. He died in London, after a few days' illness, on March 13, 1920, leaving a name in the civil service as one of the greatest administrative officials of his time.

MORAT (Ger. *Murten*), a small town on the east shore of the Lake of Morat, in the Swiss canton of Fribourg, and 14 m. N. of Fribourg or 18¼ m. W. of Bern by rail. Morat is also connected

by rail to Solothurn, Neuchâtel, Yverdon and Lausanne. In 1920 its population was 2,175, of whom 1,812 were German-speaking and 1,889 were Protestants. In 1264 it exchanged its position as a free imperial city (enjoyed since 1218) for the rule of the count of Savoy. In 1475 it was taken by the Swiss at the commencement of their war with Charles the Bold, duke of Burgundy, whose ally was the duchess of Savoy; in 1476 it was besieged by Charles (*see* SWISS WARS). Morat was ruled in common from 1475 to 1798 by Bern and Fribourg, being finally annexed to Fribourg in 1814. The Lake of Morat has an area of 10½ sq.m., and is connected with that of Neuchâtel by way of the Broye canal. On its shores many lake dwellings have been found. It is overlooked by the 13th century castle and the tower of the *Rathhaus,* while it is still surrounded by its 15th century walls that are studded at intervals with watch towers.

MORATA, OLYMPIA FULVIA (1526–1555), Italian classical scholar, was born at Ferrara. Her father knew all the learned men of the day, and she grew up in the atmosphere of classical learning. She was summoned to teach Anne, daughter of the duchess of Ferrara, when she was not much more than 12 years old, but had to leave owing to her father's conversion to Protestantism, which was later followed by her own. About the end of 1550 she married Andrew Grunthler, of Schweinfurt, Bavaria, and went to Schweinfurt with him. They were besieged by the Protestants when Albert of Brandenburg occupied the place, and finally escaped to Heidelberg in 1554. Here she died on Oct. 25, 1555.

BIBLIOGRAPHY.—The scanty remains of her works—letters, dialogues, Greek verses—were collected and published by Celio Secundo Curione (1558). Monographs by Caroline Bowles, wife of Robert Southey the poet (1834), J. Bonnet (1850; Eng. trans., Edinburgh, 1854), and R. Turnbull (Boston, 1846); *see* also Caroline Gearey, *Daughters of Italy* (1886).

MORATÍN, LEANDRO FERNÁNDEZ DE (1760–1828), Spanish dramatist and poet, the son of N. F. de Moratín. Appointed secretary to Cabarrús on a special mission to France in 1787, he was ordained on his return to Spain in 1789, and presented with a sinecure benefice and a pension, which was continued until 1816. He then adopted a literary career and succeeded Samaniego as official translator to the foreign office—a post for which his travels in England, the Low Countries, Germany and Italy eminently fitted him. An ardent admirer of Molière, he preserved, notwithstanding, his own originality, and in such plays as *El viejo y la niña* (1786), *La comedia nueva* (1792), *La Mogigata* (1804) reveals himself a subtle satirist, a delicate versifier and a master of concise dialogue. His crowning triumph in original comedy was *El Sí de las Niñas* (1806), which was performed night after night to crowded houses, ran through several Spanish editions in a year and was soon translated into a number of foreign languages. Involved in the fall of Godoy, Moratín accepted (1811) the office of royal librarian under Joseph Bonaparte—a false step, which alienated from him all sympathy and compelled him to spend his last years in exile.

MORATORIUM, a term used to express a legal authorization postponing for a specified time the payment of debts or obligations. The term is also sometimes used to mean the period over which the indulgence or period of grace stretches, the authorization itself being called a moratory law.

MORAVIA, a province of Czechoslovakia, covers an area of 8,616 sq.m. In physical structure it is a large basin, drained mainly by the Morava and its tributaries but in part by the upper Oder. North and west of a line from Znojmo through Brno to the source of the Oder it is part of the mountainous plateau which slopes southward from the Vrchovina Českomoravská, and beyond the Olomouc bay of the Morava, of the Jeseník heights (Praděd, 4,887 ft.). Both these plateaux consist of old crystalline rocks and pre-Permian, notably Devonian limestones and Carboniferous strata. South and east of the line mentioned above Tertiary and Recent deposits, *e.g.,* loess, form a fertile, undulating territory with isolated hills, rising beyond the Morava to the outer ranges of the Bílé Karpaty and the West Beskids. The most important ranges of this downland run parallel to the Carpathians and include the Chřiby (1,915 ft.) west of the Morava and its continuations the Hory Vizovské and spurs of the West Beskids, east of the river. The bay of Olomouc projects a tongue of Recent deposits and their typical human responses into the eruptive zone, where small outcrops of Cretaceous strata reproduce conditions found in the neighbouring basin of the Elbe.

The accidented relief of Moravia gives rise to great varieties of climate which in association with the different geological formations diversify its agriculture. Thus on the high western plateau the cultivated crops grade from hardy cereals, flax and potatoes through wheat and rye to maize, sugar-beet and vine in the lower sheltered valleys where conditions resemble those of the Bohemian plain. Beyond the Morava the passage is from the last-named group through cereals to fodder crops and pasture on the pervious *flysch* and limestones of the Carpathian flanks. The province contains some 16% of the acreage under wheat in Czechoslovakia, and 30% of that devoted to sugar-beet. Other crops of importance are hops (Tršice), hemp in the warm lowlands, vegetables (Znojmo and Olomouc), chicory, fruit and tobacco. Forestry is well-developed and the raising of stock includes an esteemed breed of horses from the plain of the Hana, excellent sheep in the Carpathians and fine cattle along the north-eastern border. The mineral wealth, consisting chiefly of coal and iron, is considerable. The former is mined principally in the district of Moravská Ostrava, part of the Silesian field, but smaller quantities are obtained from the Rosice-Oslavany region, west of Brno; lignite is mined at Hodonín. Iron-ores are extracted in the Moravian-Silesian borderlands, Blanskó and Rosice. Other mineral products of lesser importance are graphite (Mohelnice and Staré Město), clay and slates.

Industrially Moravia is advanced. It shares the important iron and steel working of Silesia, possessing foundries at Vitkovice and has smaller works at Rosice. Machinery is manufactured at Brno and Blanskó; much of this is for domestic use in agriculture, agricultural industries and textile manufacture. The hops and barley of Olomouc supply large breweries with a flourishing export trade, while other distributed and thriving industries arising from local agriculture are distilling and sugar-refining, and along the mountain borderland of the west starch and glucose are prepared. The cloth industry dates from the 14th century and has its powerful centre at Brno, silks are manufactured in northern Moravia, hats at Prostejov and Novy Jičín and leather goods at Brno, Prostejov and Jihlava. Other activities include saw-milling, the manufacture of furniture (Brno and Třebič) and clay products (Znojmo).

The population of Moravia in 1921 numbered 2,662,884, 78·2% being Czechoslovaks, 21% Germans and 0·6% Jews. The German element is strongest at the northern and southern ends, for Moravia has always been a great thoroughfare for movements between Vienna and south-eastern Germany, and in several of the larger towns the proportion of Germans is fairly high. By religion its people are 91% Roman Catholic, 3·2% Protestant, 2·3% Czechoslovak church and 1·8% without any confession. Educationally the standard is high and reflects both the prosperity of the province and the cultural influence of its German contacts during a long association with Austria. For administrative purposes the province is included with Silesia and the two are divided into six electoral areas for representation in the Chamber of Deputies and three for the Senate. A large measure of provincial autonomy is granted, the provincial capital being Brno.

History.—The earliest recorded inhabitants of Moravia were the Celtic Boii, who have perpetuated their name in Bohemia, and Cotini. These were succeeded about 15–10 B.C. by the Germanic Quadi, a Suabian tribe. The Germanic races were pushed back from the Middle Danube with the coming of the Avars (*q.v.*) in A.D. 567. The exact date of the arrival of the Slavs in Moravia, as in Bohemia, is uncertain; but by the late 8th century Moravia was filled with Slavonic settlers, who acknowledged no particular tribe but took the general name of Moravians (Ger. Mehranen

or Mähren) from the river Morava. When Charlemagne destroyed the Avar empire (*c.* 796), Moravia became tributary to the German empire; but its princes enjoyed much independence, repeatedly making war on the empire. It was probably for political reasons that Duke Rastislaus of Moravia invited two missionaries from the coast of Constantinople, SS. Cyril (Constantine) and Methodius, to teach Moravia Christianity (863); but in 864 Rastislaus was defeated by King Louis, and Moravia came under the Church of Rome. Having rebelled in 869, Rastislaus was defeated, blinded and banished to a monastery; but his nephew and successor Sviatopluk regained his independence (874) and founded an extensive kingdom of "Great Moravia" reaching to the Oder and Vistula and including Bohemia. After a savage war against the empire, which allied itself with the Magyars, Sviatopluk was killed (894), and Moravia "wholly destroyed" by the Magyars in 907–8. After long being disputed between Poland, Hungary and Bohemia, Moravia was incorporated in Bohemia, in 1029, thus becoming part of the German empire. In 1182 it was made a separate margravate, but was still treated in practice as a fief and secondogeniture of the king of Bohemia, who was nearly always invested with it. In 1526 Moravia, like Bohemia and Silesia, came under Habsburg rule, which its diet, unlike that of Bohemia, accepted readily. Thereafter it shared the fortunes of Bohemia (*q.v.*) with the difference that the Czech national movement was usually more moderate, partly owing to the higher proportion of German settlers, introduced at various periods. In 1849 Moravia was made a separate Austrian crownland. In Nov. 1918 it became part of Czechoslovakia (*q.v.*), being created a federated province of that State under the law of 1927.

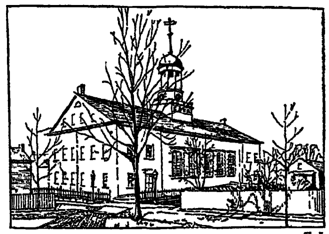
MORAVIAN BRETHREN or Moravian Church, a Christian communion founded in the east of Bohemia. For some years after the death of John Huss (1415), the majority of his followers were split into two contending factions. Some were pacified by concessions, and were recognized by the pope as the national Church of Bohemia (1433); but with this result some of Huss's followers, who wished to preserve his spiritual teaching, were not content. They laid great stress on purity of morals; and convinced that the official Church was morally corrupt, they founded a number of independent societies in Moravia and Bohemia. At this crisis Peter of Chelcic became the leader of the advanced reforming party. In ethics he anticipated much of the teaching of Tolstoy; in doctrine he often appealed to the authority of Wycliffe; and in some of his views it is possible to trace the influence of the Waldenses. He interpreted the Sermon on the Mount literally, denounced war and oaths, opposed the union of Church and State, and declared that the duty of all true Christians was to break away from the national Church and return to the simple teaching of Christ and His apostles. His followers were known as the Brethren of Chelcic, and wore a distinctive dress. His most famous supporter was John Rockycana, archbishop-elect of Prague, under whose influence the new community was founded and settled in the deserted village of Kunwald. Fresh recruits came streaming in, not only from the little societies already assisting, but also from the Waldenses, the national Church at Königgratz, and the university of Prague. They called themselves Jednota Bratrska, *i.e.*, the Church or Communion of Brethren; and this is really the correct translation of their later term, *Unitas fratrum.* At the Synod of Lhota (1467), they broke away entirely from the papacy, elected ministers of their own, and had Michael Bradacius consecrated a bishop by Stephan, a bishop of the Waldenses. At the synod of Reichenau (1495), they rejected the authority of Peter of Chelcic, and accepted the Bible as their only standard of faith and practice. In doctrine they were generally broad and radical. They taught the Apostles' Creed, rejected Purgatory, the worship of saints and the authority of the Catholic Church, practised infant baptism and confirmation, held a view on the Sacrament similar to that of Zwingli, and, differing somewhat from Luther in their doctrine of justification by faith, declared that true faith was "to know God, to love Him, to do His commandments, and to submit to His will." With the Brethren, however, the chief stress was laid, not on doctrine, but on conduct. For this purpose they instituted a severe system of discipline, divided their members into three classes—the Perfect, the Proficient, and the Beginners. They made great use of the press. In 1501 Bishop Luke of Prague edited the first Protestant hymn-book; in 1502 he issued a catechism, which circulated in Switzerland and Germany and fired the catechetical zeal of Luther; in 1565 John Blahoslaw translated the New Testament into Bohemian; in 1579–1593 the Old Testament was added; and the whole, known as the Kralitz Bible, is still in use. The constitution was practically Presbyterian. The growth of the Brethren was rapid; and by 1609, when Rudolph II. granted the *Letter of Majesty,* they were half the Protestants in Bohemia and more than half in Moravia.

At the very height of their power, however, they were almost crushed out of existence. The cause was the outbreak of the Thirty Years' War (1618). At the battle of the White Hill (1620) the Bohemian Protestants were routed; and for a hundred years the Brethren were almost extinct. But their bishop, John Amos Comenius (1592–1672), held them together. With an eye to the future, he published their *Ratio disciplinae,* and collected money for the "Hidden Seed" still worshipping in secret in Moravia. Of the "Hidden Seed" the greater number were Germans; they were probably descended from a colony of German Waldenses, who had come to Moravia in 1480 and joined the Church of the Brethren; and, therefore, when persecution broke out afresh they naturally fled to the nearest German refuge. With Christian David, a carpenter, at their head, they crossed the border into Saxony, settled down near Count Zinzendorf's estate at Berthelsdorf, and, with his permission, built the town of Herrnhut (1722–1727). But under Zinzendorf the history of the Moravians took an entirely new turn. He was a fervent Lutheran of the Pietist type, and a follower of Spener; and now he tried to apply these ideas to the Moravian refugees. For some years he had a measure of success. Instead of reviving Moravian orders at once, the settlers attended the Berthelsdorf parish church, regarded themselves as Lutherans, agreed to a code of "statutes" drawn up by the count, accepted the Augsburg Confession as their standard of faith, and, joining with some Lutheran settlers in a special Communion service in Berthelsdorf (Aug. 13, 1727), had such a powerful unifying experience that modern Moravians regard that day as the birthday of the renewed Moravian Church. They desired the re-establishment of their ancient church. In form the Moravian Church was soon restored. Before long persecution broke out against Herrnhut; the count sent a band of emigrants to Georgia; and as these emigrants would require their own ministers, he had David Nitschmann consecrated a bishop by David Ernest Jablonsky, grandson of Comenius (1735). In this way the Moravian orders were maintained; and yet, on the other hand, Zinzendorf's type of Lutheranism hampered the Brethren's progress in Germany. Instead of aiming at Church extension, they built settlements on the estates of friendly noblemen, erected Brethren's and Sisters' houses, and cultivated a quiet type of spiritual life. It is true that they evangelized all over Germany; but this part of their work was known as the Diaspora (1 Pet. i. 1); and the idea underlying this word is that the Brethren minister to the "scattered" in other Churches without drawing them into the Moravian Church. In Germany, therefore, the importance of the Moravians must be measured, not by their numbers, but by their influence upon other Christian bodies. It was from the Moravians that Schleiermacher learnt his religion, and they even made a passing impression on Goethe; but both these men were repelled by their doctrine of the substitutionary sufferings of Christ.

In reply to the very natural question why the Moravians began their work in England, the answer given by history is that John Wesley, on his voyage to Georgia (1735) met some Moravian emigrants; that on his return he met Peter Boehler, who was on his way to North Carolina; that through Boehler's influence both John and Charles Wesley were "converted" (1738). For a few years they took an active share in the Evangelical Revival (1738–

1755); but Zinzendorf's "ecclesiola" policy prevented their growth, and not till 1853 did the English Moravians resolve to aim at "the extension of the Brethren's Church." In 1749 the British Parliament recognized them as "an ancient protestant episcopal church." In foreign missions the distinctive feature about the Moravians is, not that they were so early in the field (1732), but that they were the first Protestants to declare that the evangelization of the heathen was the duty of the Church as such. Hitherto it had been a part of colonial policy. It was this that made their missions so influential.



BY COURTESY OF THE BETHLEHEM CHAMBER OF COMMERCE
MORAVIAN CHURCH BUILT AT BETHLEHEM, PA., IN 1803

Present Condition.—I. *Enterprises:* (1) Foreign missions in Labrador, Alaska, Canada, California, West Indies, Nicaragua, Demerara, Surinam, Cape Colony, Kaffraria, German East Africa, North Queensland, West Himalaya. (2) Leper Home near Jerusalem (1867). (3) Diaspora in Germany, Switzerland, France, Denmark, Norway, Russia, Poland. (4) Church extension in Germany, Great Britain, North America. (5) Boarding Schools: German province, 14; British, 7; American, 5. (6) Church Revival in Bohemia and Moravia, begun in 1869, and sanctioned by the Austrian government (1880). In Germany the official title of the Church is *Evangelische Brüder-Unität;* in Austria, *Evangelische Brüder-Kirche;* in England and America, *Moravian Church.*

II. *Doctrine.*—At the General Synod of 1909 they reaffirmed their old fundamental principle that "the Holy Scriptures are our only rule of faith and practice"; but at the same time they declared that their interpretation of Scripture agreed substantially with the Nicene Creed, the Westminster and Augsburg Confessions, and the Thirty-nine Articles. Since 1879 their leading doctrines have been formulated as follows: (1) the total depravity of man; (2) the real Godhead and real humanity of Christ; (3) justification and redemption through the sacrifice of Christ; (4) work of the Holy Spirit; (5) good works as fruits of the Spirit; (6) fellowship of believers; (7) second coming of Christ; (8) resurrection of the dead to life or judgment.

III. *Ceremonies.*—At morning worship the service consists of a litany, scripture lessons, sermon, singing, extempore prayer. At the evening service a litany is rarely used. The Communion is celebrated once a month. Infant Baptism is practised. There are three modes of admission to membership: in the case of the unbaptized, adult baptism (not immersion); in other cases confirmation or reception.

IV. *Church Policy.*—It is now held by some Moravians that their Church offers a *via media* between Anglicanism and Dissent. At the meeting of the Lambeth Conference in 1907 some overtures, on certain conditions, were made for (*a*) joint consecration of bishops, (*b*) joint ordination of ministers, (*c*) interchange of pulpits. In response the Moravians, at the General Synod (1909), welcomed the offer, but also declared their wish (*a*) to preserve their independence as a "Protestant Episcopal Church"; (*b*) to co-operate freely as heretofore with other Evangelical Churches.

General Statistics (Communicants), 1928

British Province (42 Congregations, including Home Missions)	3,520
Continental Province (24 Congregations)	7,723
America—Northern Prov. (98 Cong.)	18,029
America—Southern Prov. (38 Cong.)	7,791
Czecho-Slovakia (7 Cong.)	1,503
Missions (390 Stations and Out-stations)	39,902
Missionaries (European and American)	260
Missionaries (European [Native])	2,127
Total	80,855

The United States.—The *Unitas Fratrum,* Brethren's Unity, known better in America as the Moravian Church, occupies a unique position among the churches coming to or arising in the United States, in these respects: it was the first to form an act upon the idea of converting heathen peoples, beginning at once among the Eskimos of the Arctic shores and the Indians of North America. It has gained more members among the heathen than it has had in its home churches. It has preserved its unity from a single division. It is the only Protestant Church to be under a single general supervision in its German, English and American territories, and the only one that has had from the first an unquestioned apostolic succession for its episcopate.

The Moravians began to arrive in Georgia and in Pennsylvania in the first half of the 18th century. The company that came to Georgia in 1735 removed to Pennsylvania, where other companies from abroad joined them, including Count Zinzendorf, who won the confidence of neighbouring Indians, the Six Nations, including permission to sojourn at will among the Iroquois. He also organized a church of six members at Skeksmeter, N.Y., among the Mohicans. In an attempt to unite German immigrants of the Lutheran and Reformed faiths, who had scarcely been able to organize themselves, he was less successful, though many conferences or synods were held; but meantime he brought about the organization of Moravian churches in Bethlehem, Nazareth and elsewhere and saw economical community settlements, like that of his own Herrnhut in Germany, begin at Bethlehem and Nazareth. These communities ceased to exist in 1856. The Moravian church did not develop rapidly in the United States, following in this respect the history of the denomination in Germany and Great Britain, perhaps because it was so greatly absorbed in developing its work among the heathen, Indians and Orientals. It sent, it may be, too many of its ministers and bishops to the pagans. Since the World War the missionary management has been divided and the foreign missions apportioned among the American and other provinces. The Church in America has for many years been organized into two provinces, the northern with its headquarters at Bethlehem, Pa., and the southern centring at Salem, N.C. At Bethlehem are the Missions Board and a Publication Society, with Church Extension and Sustentation societies. In 1927 the church in the United States had 150 ministers, 134 churches and 26,241 communicants. (H. K. C.)

See J. Taylor Hamilton, *The Moravian Church* (1895).

MORAVSKÁ OSTRAVA, the third city in Czechoslovakia, pop. (1921) 113,709, has valuable coal deposits. On the opposite bank of the Ostrawitsa is Ostrava Slezská, pop. (1921) 22,890.

MORAY,[1] THOMAS RANDOLPH, 1ST EARL OF (d. 1332), Scottish warrior and statesman, was the only son of Thomas Randolph of Nithsdale, who had been chamberlain of Scotland, and through his mother Lady Isabel Bruce was nephew to King Robert the Bruce. In June 1306, he was captured at Methven, and saved his life by becoming Edward's man. In 1308, however, he was taken by Sir James Douglas and imprisoned. Having made his submission, in 1312 or 1314 he was created earl of Moray and lord of Man and Annandale by the Scottish king. By a brilliant feat of arms he destroyed Edinburgh Castle early in 1314, and drove back the English at Bannockburn. He shared in Edward Bruce's expedition to Ireland in 1315, and returned to Scotland in 1317 with Robert Bruce. With Sir James Douglas, Randolph was closely allied; in 1318 they seized Berwick and in 1319 they raided the northern English counties, laying waste the country as far as York, and securing a two years' truce with Edward II.

In 1322 Moray shared in Douglas's exploit at Byland Abbey. In the next year he was one of the Scottish ambassadors charged

[1]In general, for "Moray" *see* MURRAY, the spelling having been constantly interchangeable. The present earls keep the spelling Moray.

to conclude a truce with England, and was sent to Avignon to persuade the pope to acknowledge Bruce's claims. In 1326 he concluded an offensive and defensive alliance between France and Scotland. The death of Bruce in 1329 made Moray regent of Scotland and guardian of the young king David II. He died at Musselburgh on July 20, 1332.

MORAY or **ELGINSHIRE** (Gaelic "among the sea-board men"), northern county, Scotland, bounded north by the Moray firth, east and south-east by Banffshire, south and south-west by Inverness and west by Nairnshire. It comprises only the eastern portion of the ancient province of Moray, which extended from the Spey to the Beauly and from the Grampians to the sea, embracing an area of about 3,900 sq. miles. The area of the county excluding water, is 477 sq.m. (305,931 acres). The county is divided between lowland and hill country. The lowland of the coast and its hinterland is the Laigh of Moray, a fertile tract 30 m. long and 5 to 12 m. broad, of old red sandstone and Triassic strata, with a wide distribution of glacial deposits, which were carried from the heights in an easterly and south-easterly direction along the present Moray firth. The sandstones at and near Quarry Wood are of special geological interest on account of their remarkable series of reptilian remains, which date them, at least in part, as Triassic, and possibly, in the lowest portion as Permian. The hilly south-central division of the county reaches a greatest height of 2,329 ft. in the Cromdale hills on the Banffshire border. This division belongs to the area of the crystalline schists of the central highlands, with granite between Lochindorb and Grantown. The two most important rivers, the Spey (*q.v.*) and the Findhorn, have their sources in Inverness-shire. About 50 m. of the course of the Spey are in Moray, to which it may be roughly said to serve as the boundary line on the south-east and east. The Findhorn rises in the Monadliadh mountains which form the watershed for several miles between it and the Spey. Of its total course of nearly 70 m. only the last 12 are in the county, before it enters the Moray firth in a bay on the north-eastern shore to which it has given its name. The Lossie rises in the small lakes on the flanks of Carn Kitty and pursues a winding course of 34 m. to the Moray firth. The Spey and Findhorn are famous for salmon, and some of the smaller streams afford good sport.

Lochindorb, 6 m. north-north-west of Grantown, is now the largest lake. In the upper end, on an island believed to be artificial, stand the ruins of Lochindorb castle, in the 14th century the stronghold of the Wolf of Badenoch, and afterwards successively the property of the earl of Moray, the Campbells of Cawdor and the earl of Seafield. In the southern half of the county are several fine glens, including Rothes, Lossie, Gheallaidh, Tulchan and Beag. Strathspey is a broader and beautiful valley.

Agriculture.—Considering its latitude and the extent of its arable land the standard of farming in Moray is high. The rich soil of the lowlands is well adapted for oats and barley. The breeding of live-stock is profitable, and some of the finest specimens of shorthorned and polled cattle and of crosses between the two are bred. On the larger farms in the Laigh Leicester sheep are kept all the year round, but in the uplands the Black-faced take their place. Horses and pigs are also raised.

Other Industries.—Whisky is the chief product. There are woollen mills, distilleries, sawmills and iron foundries at Elgin; woollen mills, distilleries and chemical works at Forres; and distilleries at Rothes. Owing to the absence of coal, what little mineral wealth there is (iron and lead) cannot be remuneratively worked. The sandstone quarries, yielding a building-stone of superior quality, are practically inexhaustible. The plantations mainly consist of larch and fir and, to a smaller extent, of oak. The Firth fisheries, comprising haddock, cod, herring, etc., are of considerable value.

Population and Government.—The population was 40,805 in 1931, when 532 persons spoke both Gaelic and English. The chief towns are Elgin (pop. in 1931, 8,810), Forres (4,169) and Lossiemouth (3,914), to which may be added Rothes (1,292), Grantown-on-Spey (1,577) and Burghead (1,255). In conjunction with Nairnshire the county returns one member to parliament. Elgin and Forres are royal burghs; the municipal and police burghs include Burghead, Elgin, Forres, Grantown-on-Spey, Lossiemouth, and Rothes. Moray is included in one sheriffdom with Inverness and Nairn, and there is a resident sheriff-substitute at Elgin. The county is under school-board jurisdiction, several of the schools earning grants for higher education. There are an academy, a school of science and art and a technical school at Elgin.

History.—The stone circle at Viewfield is an interesting prehistoric monument. Christianity, introduced under the auspices of Columba (from whose time the site of Burghead church has probably been so occupied), flourished for a period until the Columban church was expelled in 717 by King Nectan. Thereafter the district was given over to internecine strife between the northern and southern Picts, which was ended by the crushing victory of Kenneth MacAlpine in 831, as one result of which the kingdom of Pictavia was superseded by the principality of Moravia. Later the Norsemen raided the country first under Thorstein and then under two Sigurds. It was in the time of the second Sigurd that the Firth was fixed as the northern boundary of Moray. In spite of such interruptions as the battle of Torfness (Burghead) in 1040, in which Thorfinn, earl of Orkney and Shetland, overthrew the Scots under King Duncan, the consolidation of the kingdom was being gradually accomplished. After Macbeth ascended the throne the Scandinavians held their hands. Though Macbeth and his *fainéant* successor, "daft" Lulach, were the only kings whom Moray gave to Scotland, the province continued under the rule of its own marmaer, or great steward until the dawn of the 12th century, when as an entity it ceased to exist. With a view to breaking up the power of the marmaers, David I. and his successors colonized the seaboard with settlers from other parts of the kingdom, but from time to time the clansmen and their chiefs descended from their fastnesses and plundered the Laigh. Meanwhile, the Church had become a civilizing force. In 1107 Alexander had founded the see of Moray and the churches of Birnie, Kinneddar and Spynie were in turn the cathedral of the early bishops, until in 1224 under the episcopate of Andrew of Moray (de Moravia), the church of the Holy Trinity in Elgin was chosen for the cathedral. Another unifying factor was the struggle for independence.

In his effort to stamp out Scottish nationality Edward I. came as far north as Elgin in 1296. Wallace, however, was well supported by Sir Andrew Moray of Bothwell, and Bruce recognized the assistance he had received from the men of the north by erecting Moray into an earldom on the morrow of Bannockburn and bestowing it upon Thomas Randolph. (*See* MORAY, THOMAS RANDOLPH, EARL OF.) Henceforward the history of the county resolved itself in the main into matters affecting the power of the Church and the ambitions of the Moray dynasties. There was strife between Covenanters and the adherents of Episcopacy until, prelacy itself being abolished in 1689, the bishopric of Moray came to an end after an existence of 581 years. (For the subsequent history of the earldom *see* MURRAY or MORAY, EARLS OF.) Other celebrated Moray families who played a part in local politics were the Gordons, the Grants and the Duffs. Still, national affairs occasionally evoked interest in Moray. In the civil war Montrose ravaged the villages which stood for the Covenanters, but most of the great lairds shifted in their allegiance, and the mass of the people were quite indifferent to the declining fortunes of the Stewarts. Charles II. landed at Garmouth on July 3, 1650, on his return from his first exile in Holland. The fight at Cromdale (May day, 1690) shattered the Jacobite cause, for the efforts in 1715 and 1745 were too spasmodic and half-hearted to affect the loyalty of the district to Hanoverian rule. A few weeks before Culloden Prince Charles Edward stayed in Elgin for some days, and a month afterwards the duke of Cumberland passed through and administered the *coup de grâce* to the Young Pretender on Drummossie moor.

Elginshire has twice been the scene of terrible catastrophes. In 1694 the barony of Culbin—a fine estate, comprising 3,600 ac. of land, so fertile that it was called the Granary of Moray, a mansion, a church and several houses—was buried under a mass of sand in a severe storm. This sandy waste, north-west of

Forres, measures 3 m. in length and 2 in breadth. The other calamity was the Moray floods of Aug. 2 and 3, 1829. The Findhorn inundated an area of 20 sq.m.; the Divie rose 40 ft., and the Lossie flooded all the low ground around Elgin.

MORBIHAN, a department of western France on the Atlantic seaboard, formed of part of Lower Brittany, and bounded S.E. by the department of Loire-Inférieure, E. by that of Ille-et-Vilaine, N. by Côtes-du-Nord, and W. by Finistère. Area, 2,738 sq. miles. Pop. (1926) 543,175. The department is formed of the denuded folds of the Armorican system, which have axes of granitic rocks running for the most part E.S.E. to W.N.W. The most northerly of these stretches into the department from the Montagnes Noires of S. Finistère, and in Morbihan reaches a height of 974 ft. The next ridge to the south runs across the centre of the department and dies down on its east and west borders; it forms the barren Landes de Lanvaux, about 1 to 3 m. wide and 31 m. long. Parallel lines of granite and Archaean rock also form most of the coast. The Blavet river on the west runs across the structural lines and has some pretty valley sections where it cuts across the harder axes. The Oust is a tributary of the Vilaine, which it joins at the east end of the Landes. The great feature of the department is its coastline, with a number of picturesque estuaries, formed through invasion of river valleys by the sea, and the Morbihan, or "little sea," studded with islands, which are classic ground for the student of prehistoric archaeology. The Morbihan is separated from the sea outside, the Mor Braz, by the peninsula of Ruis, save for a tide-race at the end of the peninsula. To the west is the peninsula of Quiberon, which is joined to the mainland by a long sandspit. Off the coast lie the islands of Groix, Belle-Île (*q.v.*), Houat and Hoedik.

The climate of Morbihan is moist and mild. Unproductive heath occupies more than a quarter of the department, about a third of which is arable land. The shores of the estuaries are rich in southern plants, figs, rose-laurels, aloes, etc. Rye, buckwheat, wheat and oats, potatoes and mangels are the chief crops; hemp and flax are also grown. Horned cattle are the chief livestock and bee-keeping is important. Seaweed is used for manure. Lorient (*q.v.*) is a shipbuilding centre, while the sardine, oyster (Auray, St. Armel, etc.), anchovy and lobster fisheries are important, as is fish-preserving. Hennebont makes sheet-tin for sardine-boxes. There are several slate-quarries, and a number of minor industries, including lace-making by hand.

The department is served by the Orléans railway and the canal from Nantes to Brest uses the Oust; the Blavet is also canalised. It is divided into three arrondissements, namely: Vannes, Lorient, and Pontivy—with 38 cantons and 260 communes. The capital Vannes is the seat of a bishopric of the province of Rennes. The department belongs to the region of the XIth army corps (Nantes) and to the académie (educational division) of Rennes, where also is its court of appeal. The principal places are Vannes, Lorient, Ploërmel, Pontivy, Auray, Hennebont, Carnac and Locmariaquer, the last two famous for megalithic monuments, as are Erdeven and Plouharnel; Elven, with two towers of the 15th century, remains of an old stronghold; Josselin which has the fine château of the Rohan family and a church containing the tomb (15th century) of Olivier de Clisson and his wife; Guern with a chapel of the 15th and 16th centuries and Le Faouët with a chapel of the 15th century; Quiberon, associated with the disaster of the French *émigrés* in 1795; Sarzeau, near which is the fortress of Sucinio (13th and 15th centuries); Ste. Barbe with a chapel, dating from about the end of the 15th century, finely situated, overlooking the Ellé; St. Gildas-de-Ruis, with a Romanesque church and other remains of a Benedictine abbey of which Abelard was for a time abbot. The principal *pardons* (religious festivals) are those of Ste. Anne-d'Auray and St. Nicolas-des-Eaux.

MORCAR or **MORKERE, EARL** (*fl.* 1066), earl of the Northumbrians, son of Earl Aelfgar, brother of Edwin, earl of the Mercians. He assisted the Northumbrians to expel Tostig, of the house of Godwin, in 1065 and was chosen earl by the rebels, an election which Tostig's brother, Harold, later accepted. In spite of the help which Harold afterwards gave them against Tostig and Harold Hardrada, the two brothers left him to fight alone at Hastings. After trying to secure the crown for their own house, they submitted to William, but lost their earldoms. They attempted unsuccessfully to raise the North in 1068. They were pardoned, but Morcar afterwards joined Hereward in the Isle of Ely (1071), and later died in prison.

See E. A. Freeman, *Norman Conquest* vols. 2–4 and *William Rufus*, vol. i.

MORDVINIANS, otherwise called MORDVA, MORDVS, or MORDVINS, a people numbering about one million, speaking a Finno-Ugrian language, who inhabit the middle Volga provinces of Russia and spread in small detached communities to the south and east of these. Their settlement in the basin of the Volga is of high antiquity. There are two dialects Erza and Moksha. The southern branch, or the Moksha, have a darker skin and darker eyes and hair than the northern. A third branch, the Karatays, found in Kazan, appears to be mixed with Tatars. The Mordvins have maintained a good deal of their old national dress, especially the women, whose profusely embroidered skirts, original hair-dress, large ear-rings which sometimes are merely hare-tails, and numerous necklaces covering all the chest and consisting of all possible ornaments, easily distinguish them from Russian women. They have mostly dark hair, blue eyes, generally small and rather narrow. They are generally roundish headed, finely built, rather tall and strong, and broad-chested. Their chief occupation is agriculture. They now manufacture wooden ware of various sorts. They are also masters of apiculture. They have a considerable literature of popular songs and legends, some of them recounting the doings of a king Tushtyan who lived in the time of Ivan the Terrible. Nearly all are Christians; they received baptism in the reign of Elizabeth, and the Nonconformists have made many proselytes among them. But they still preserve much of their own mythology, which they have adapted to the Christian religion. According to some authorities, they have preserved also, especially the less russified Moksha, the practice of kidnapping brides, with the usual battles between the party of the bridegroom and that of the family of the bride. The worship of trees, water (especially the water-divinity which favours marriage), the sun or Shkay, who is the chief divinity, the moon, the thunder and the frost, and of the home-divinity Kardazserko still exists among them; and a small stone altar or flat stone covering a small pit to receive the blood of slaughtered animals can be found in many houses. Their burial customs seem founded on ancestor-worship. On the fortieth day after death the dead person is supposed to return home. One of his household represents him, and, coming from the grave, speaks in his name.

The language is treated of in Ahlquist's *Versuch einer Mokscha-mordwinischen Grammatik nebst Texten und Wörter-Verzeichniss* (St. Petersburg, 1861), and their history, customs and religion by Smirnov (trans. by Boyer), "Les Populations finnoises de la Volga" (in *Publications de l'école des langues orientales, vivantes*, 1898). Much valuable information respecting customs, religion, language and folk-lore will be found in papers by Paasonen, Heikel, Ahlquist, Mainof and others printed in the *Journal de la Société Finno-Ougrienne* and the *Finnisch-ugrische Forschungen.*

MORE, HANNAH (1745–1833), English religious writer, was born at Stapleton, near Bristol, on Feb. 2, 1745. She may be said to have made three reputations in the course of her long life: first, as a clever verse-writer and witty talker in the circle of Johnson, Reynolds and Garrick; next, as a writer on moral and religious subjects on the Puritanic side; and lastly, as a practical philanthropist. She was the youngest but one of the five daughters of Jacob More, who, though a member of a Presbyterian family in Norfolk, had become a member of the English Church and a strong Tory. He taught a school at Stapleton in Gloucestershire. The elder sisters established a boarding-school at Bristol, and Hannah became one of their pupils when she was 12 years old. Her first literary efforts were pastoral plays, the first being written in 1762 under the title of *A Search after Happiness* (2nd ed. 1773). Metastasio was one of her literary models; on his opera of *Attilio regulo* she based a drama, *The Inflexible Captive,* published in 1774. She gave up her share in the school on contracting an engagement of marriage with a Mr. Turner. The wedding never took place, and Hannah More

accepted from Turner an annuity which had been settled on her without her knowledge. This set her free for literary pursuits, and in 1772 or 1773 she went to London. Some verses on Garrick's *Lear* led to an acquaintance with the actor-playwright; Miss More was taken up by Elizabeth Montague; and her unaffected enthusiasm, simplicity, vivacity, and wit won the hearts of the whole Johnson set, the lexicographer himself included, although he is said to have told her that she should "consider what her flattery was worth before she choked him with it." Garrick wrote the prologue and epilogue for her tragedy *Percy,* acted at Covent Garden in Dec. 1777. Another drama, *The Fatal Falsehood,* produced in 1779 after Garrick's death, was less successful. The Garricks had induced her to live with them; and after Garrick's death she remained with his wife. In 1781 she met Horace Walpole, and corresponded with him from that time.

Hannah More published *Sacred Dramas* in 1782, and it rapidly ran through 19 editions. These and the poems *Bas-Bleu* and *Florio* (1786) mark her gradual transition to more serious views of life, which were fully expressed in prose in her *Thoughts on the Importance of the Manners of the Great to General Society* (1788), and *An Estimate of the Religion of the Fashionable World* (1790). She was intimate with Wilberforce and Zachary Macaulay, with whose evangelical views she was in entire sympathy. She published a poem on *Slavery* in 1788. In 1785 she bought a house, at Cowslip Green, near Wrington, near Bristol, where she settled down to country life with her sister Martha, and wrote many ethical books and tracts: *Strictures on Female Education* (1799), *Hints towards forming the Character of a Young Princess* (1805), *Coelebs in Search of a Wife* (only nominally a story, 1809), *Practical Piety* (1811), *Christian Morals* (1813), *Character of St. Paul* (1815), *Moral Sketches* (1819). The tone is uniformly animated; the writing fresh and vivacious; and there was an originality and force in her way of putting commonplace sober sense and piety that accounts for her popularity.

The most famous of her books was *Coelebs in Search of a Wife,* which had an enormous circulation. The model Stanley children were said to have been drawn from T. B. Macaulay and his sister. She also wrote many spirited rhymes and prose tales, the earliest of which was *Village Politics* (1792), by "Will Chip," to counteract the doctrines of Tom Paine and the influence of the French Revolution. The success of *Village Politics* induced her to begin the series of "Cheap Repository Tracts," which were for three years produced by Hannah and her sisters at the rate of three a month. Perhaps the most famous of these is *The Shepherd of Salisbury Plain,* describing a family of phenomenal frugality and contentment. This was translated into several languages. Two million copies of these rapid and telling sketches were circulated in one year, teaching the poor in rhetoric of most ingenious homeliness to rely upon the virtues of content, sobriety, humility, industry, reverence for the British Constitution, hatred of the French, trust in God and in the kindness of the gentry.

Perhaps the best proof of Hannah More's sterling worth was her indefatigable philanthropic work for the children in the mining districts of the Mendip hills. The More sisters met with a good deal of opposition. The farmers thought that education, even to the limited extent of learning to read, would be fatal to agriculture, and the clergy, whose neglect she was making good, accused her of Methodist tendencies. In her old age, philanthropists from all parts made pilgrimages to see the bright and amiable old lady, and she retained all her faculties till within two years of her death, dying at Clifton, where the last five years of her long and, for the most part, singularly happy life were spent, on Sept. 7, 1833.

See H. Thompson *The Life of Hannah More, with Notices of Her Sisters* (1838). The article in the *Dict. Nat. Biog.* is by Sir Leslie Stephen. Some letters of Hannah More, with a very slight connecting narrative were published in 1872 by William Roberts as *The Life of Hannah More. See* also *Hannah More* (1888), by Charlotte M. Yonge, in the "Eminent Women" series, and other lives by "Marion Harland," (1900) and Miss Meakin (1911). *Letters of Hannah More to Zachary Macaulay* were edited (1860) by Arthur Roberts. The contemporary opposition to her may be seen in an abusive *Life of Hannah More, with a Critical Review of Her Writings* (1802), by the "Rev. Archibald Macsarcasm" (William Shaw, rector of Chelvey, Somerset).

MORE, HENRY (1614–1687), English philosopher of the Cambridge Platonist school, was born at Grantham in 1614. Both his father and his mother, he tells us, were "earnest followers of Calvin," but he himself "could never swallow that hard doctrine." In 1631 he was admitted at Christ's college, Cambridge, about the time Milton was leaving it. He immersed himself "over head and ears in the study of philosophy," and fell for a time into a scepticism, from which he was delivered by a study of the "Platonic writers." He was fascinated especially by Neoplatonism, and this fascination never left him. The *Theologia germanica* also exerted a permanent influence over him. He took his bachelor's degree in 1635, his master's degree in 1639, and immediately afterwards was chosen fellow of his college. Fifteen years after the Restoration he accepted a prebend in Gloucester cathedral, but only to resign it in favour of his friend Dr. Edward Fowler, afterwards bishop of Gloucester. He would not accept the mastership of his college, to which, it is understood, he would have been preferred in 1654, when Cudworth was appointed. He drew around him many young men of a refined and thoughtful turn of mind, but among all his pupils the most interesting was Lady Conway, at whose country seat at Ragley, Warwickshire, More continued at intervals to spend "a considerable part of his time." Amidst the woods of this retreat he composed several of his books. The spiritual enthusiasm of Lady Conway was a considerable factor in some of More's speculations, none the less that she at length joined the Quakers. She became the friend not only of More and Penn, but of Baron van Helmont and Valentine Greatrakes, mystical thaumaturgists of the 17th century. Ragley became a centre not only of devotion but of wonder-working spiritualism (*cf.* the account in the novel *John Inglesant* ch. xv.). From this, his genius suffered, and the rationality which distinguishes his earlier is much less conspicuous in his later works. He was a voluminous writer both in verse and in prose. His most notable work, the *Divine Dialogues* (1688), summarizes his general view of philosophy and religion.

Henry More represents the mystical and theosophic side of the Cambridge movement. The Neoplatonic extravagances which lay hidden in the school from the first came in his writings to a head, and merged in pure phantasy. Mystical elevation was the chief feature of his character, a certain radiancy of thought which carried him beyond the common life without raising him to any artificial light, for his humility and charity were not less conspicuous than his piety. He died on Sept. 1, 1687, and was buried in the chapel of the college he loved.

Before his death More issued complete editions of his works, his *Opera theologica* in 1675, and his *Opera philosophica* in 1678. The chief authorities for his life are Richard Ward's *Life* (1710); the prefatio generalissima prefixed to his *Opera omnia* (1679); and also a general account of the manner and scope of his writings in an *Apology* published in 1664. The collection of his *Philosophical Poems* (1647), in which he has "compared his chief speculations and experiences," should also be consulted. An elaborate analysis of his life and works is given in Tulloch's *Rational Theology,* vol. ii. (1874); *see* also R. Zimmermann, *Henry More und die vierte Dimension des Raums* (Vienna, 1881). *See* ETHICS.

MORE, PAUL ELMER (1864–), American author, was born in St. Louis (Mo.), Dec. 12, 1864. He was educated at Washington university and Harvard, and he was assistant in Sanskrit at Harvard, 1894–95, and associate in Sanskrit and classical literature at Bryn Mawr college, 1895–97. He was literary editor of the *Independent,* 1901–3, and of the New York *Evening Post,* 1903–9, and editor of the *Nation,* 1909–14, in these capacities doing much to develop taste and maintain high critical standards in America.

He is the author, among other works, of *Shelburne Essays* (11 vols., 1904–21); *Life of Benjamin Franklin* (1900); *Nietzsche* (1912); *The Religion of Plato* (1921); *Hellenistic Philosophies* (1923); and *The Christ of the New Testament* (1924).

MORE, SIR THOMAS (1478–1535), English lord chancellor, and author of *Utopia,* was born in Milk street in the City of London, on Feb. 7, 1478. He attended St. Anthony's School in Threadneedle street, at that time under Nicolas Holt, and at thirteen was early placed in the household of Cardinal Morton, archbishop of Canterbury. Young Thomas More obtained this

privilege through the influence of his father, Sir Thomas, then a rising barrister and afterwards a justice of the court of king's bench. About 1492 young More was sent to Canterbury Hall, Oxford, afterwards absorbed in Christ Church, where he is said vaguely to have had Colet, Grocyn and Linacre for his tutors. All More himself says is that he had Linacre for his master in Greek. More's father, who intended his son to make law his career, feared the influence of the "new learning," and removed him from the university about 1494, and entered him at New Inn. In February 1496 More was admitted at Lincoln's inn. In his professional studies More early distinguished himself and was appointed reader-in-law in Furnival's inn; but he would not relinquish the studies which had attracted him in Oxford. Erasmus says that he tried his hand at "little comedies," and he studied Pico della Mirandola. Among his friends were Lily and Colet, the latter of whom became his confessor and exercised great influence over him. The balance of his faculties seemed to be restored by a revival of the antagonistic sentiment of humanism which he had imbibed from the Oxford circle of friends, and from Erasmus. More's acquaintance with Erasmus might have begun during Erasmus's first visit to England in 1497. Tradition has dramatized their first meeting into the story given by Cresacre More—that the two happened to sit opposite each other at the lord mayor's table, that they got into an argument during dinner, and that, in mutual astonishment at each other's wit and readiness, Erasmus exclaimed, "Aut tu es Morus, aut nullus," and the other replied, "Aut tu es Erasmus, aut diabolus!" The acquaintance rapidly ripened into warm attachment. This contact with the prince of letters revived in More the spirit of the "new learning," and he returned with ardour to the study of Greek. He acquired facility in the Greek language, from which he made and published some translations. His Latin style, though wanting the inimitable ease of Erasmus, is yet in copiousness and propriety much above the ordinary Latin of the English scholars of his time.

At about this time More desired to give himself over to an ascetic life. He took a lodging near the Charterhouse, and subjected himself to the discipline of a Carthusian monk. He wore a sharp shirt of hair next his skin, scourged himself every Friday and other fasting days, lay upon the bare ground with a log under his head, and allowed himself but four or five hours' sleep. This phase lasted for some four years 1499 to 1503. He then abandoned all idea of leaving the world, but to the end of his life he was scrupulous in the observance of his religious duties.

More sat in the parliament of 1504, when he contested Dudley's demand on behalf of the king for an "aid" in money on the marriage of Princess Margaret. More's speech is said to have moved the house to reduce the subsidy of three-fifteenths which the Government had demanded to £30,000. Henry VII. revenged himself upon More's father, who was sent to the Tower, and only released on payment of a fine of £100. Thomas More found it advisable to withdraw from public life for a time. During this period of retirement the old dilemma recurred. One while he devoted himself to the sciences, "perfecting himself in music, arithmetic, geometry and astronomy, learning the French tongue, and recreating his tired spirits on the viol," or translating Greek epigrams; another while resolved to take priest's orders.

But at this time he made acquaintance with the family of John Cult of New Hall, in Essex. The "honest and sweet conversation" of the three daughters attracted him, and though his inclination led him to prefer the second he married the eldest, Jane, in 1505, not liking to put the affront upon her of passing her over in favour of her younger sister. The newly-married pair settled in Bucklersbury, and lived a life of unbroken domestic felicity. At Bucklersbury he was visited by Erasmus, and on a second visit in 1508 the great scholar wrote the *Moriae Encomium*, dedicated to his friend and host. His wife died in 1511, and he married, within a month, Alice Middleton, a widow with one daughter. They moved to Crosby place, Bishopsgate.

The death of the old king in 1509 restored More to the public career for which his abilities specially fitted him. From this time there was scarce a cause of importance in which he was not engaged. His professional income amounted to £400 a year, equal to £4,000 in present money, and, "considering the relative profits of the law and the value of money, probably indicated as high a station as £10,000 at the present day" (Campbell). In 1509 he was elected a bencher of Lincoln's inn, and in 1510 was appointed under-sheriff of London. He soon attracted the attention of the young king and of Wolsey. It was during a residence in Antwerp that he met Peter Giles (Aegidius), a friend of Erasmus, and sketched out the idea of *Utopia*. He was repeatedly employed on embassies to the Low Countries, and was for a long time stationed at Calais as agent in the shifty negotiations carried on by Wolsey with the court of France. The spirit with which he pleaded before the Star Chamber in a case of *The Crown* v. *The Pope* marked him out for employment. More obtained in this case judgment against the Crown. Henry, who was present in person at the trial, had the good sense not to resent the defeat, but took the counsel to whose advocacy it was due into his service. In 1518 More was made master of requests, and sworn a member of the privy council. He was now compelled to resign his post of under-sheriff to the city and his private practice at the bar. In 1521 he was knighted and appointed sub-treasurer to the king, and was again sent on mission to Calais and the Low Countries. In the parliament of 1523 he was elected Speaker on Wolsey's nomination. The choice of this officer rested nominally with the house itself, but in practice was always dictated by the court. Many apocryphal stories have grown round More's speakership. In fact the records of the House do not justify Roper's account of his independent attitude.

In 1525 More was appointed chancellor of the duchy of Lancaster, and no pains were spared to attach him to the court. The king frequently sent for him into his closet, and discoursed with him on astronomy, geometry and points of divinity. This growing favour, by which many men would have been carried away, did not impose upon More, who understood the fickleness of royal favour. Then the king began to come himself to More's house at Chelsea (he had bought his house there in 1523) and would dine with him without previous notice. William Roper, husband of More's eldest daughter, mentions one of these visits, when the king after dinner walked in the garden by the space of an hour holding his arm round More's neck. Roper afterwards congratulated his father-in-law on the distinguished honour which had been shown him. "I thank our Lord," was the reply, "I find his grace my very good lord indeed; and I believe he doth as singularly favour me as any subject within this realm. Howbeit, son Roper, I may tell thee I have no cause to be proud thereof, for if my head would win him a castle in France it should not fail to go." As a last resource More tried the expedient of silence, dissembling his wit and affecting to be dull. This had the desired effect so far that he was less often sent for.

But it did not alter the royal policy, and in 1529, when a successor had to be found for Wolsey, More was raised to the chancellorship. He was the first layman to hold the office. The selection was justified by More's high reputation, but it was also significant of the modification which the policy of the court was then undergoing. It was a concession to the rising popular party, to which it was supposed that More's politics inclined him. The public favour with which his appointment had been received was justified by his conduct as judge in the court of chancery. Having heard causes in the forenoon between eight and eleven, after dinner he sat again to receive petitions. The meaner the suppliant was the more affably he would speak to him and the more speedily he would despatch his case. Business was despatched with unprecedented regularity. One morning being told by the officer that there was not another cause before the court, he ordered the fact to be entered on record, as it had never happened before. He usually, but not always, refused all the customary gifts, and did not permit his connections to interfere with the course of justice. One of his sons-in-law, Heron, having a suit in the chancellor's court, and refusing to agree to any reasonable accommodation, because the judge "was the most affectionate father to his children that ever was in the world," More thereupon made a decree against him. On the other hand he appears to have been merciless in his treatment of heretics. In the epitaph

which he wrote, he described himself as *hereticis molestus,* and, although the accusations of Protestants may be discounted, his own words and unimpeachable documents bespeak his severity.

But in raising More to the chancellorship, the king had counted upon his support in his desired divorce from Queen Catherine and in the church policy to which he was driven by that desire. More signed the articles of Wolsey's impeachment, but he had no share in the proclamation which ordered the clergy (Feb. 11, 1531) to acknowledge Henry as the supreme head of the church, "so far as the law of Christ will allow." As Henry's policy developed further, More found himself increasingly at variance with it. The divorce was a point upon which he would not yield. And, as he saw that the marriage with Anne Boleyn was determined upon, he petitioned the king to be allowed to resign the Great Seal, alleging failing health. The resignation was accepted, on May 10, 1532. More left office, as he had entered it, a poor man. His necessitous condition was so notorious that the clergy in convocation voted him a present of £5,000. This he peremptorily refused, either for himself or for his family, declaring that he "had rather see it all cast into the Thames." Yet the whole of his income after resigning office did not exceed £100 a year.

But although More strictly abstained from public activities Henry resented his absence from court and his silence. More refused to attend the coronation of Anne Boleyn, and from that moment was marked out for vengeance. A first attempt made to bring him within the meshes of the law failed. He was summoned before the privy council to answer to a charge of receiving bribes in the administration of justice. The charge was easily refuted. A bill was brought into parliament (Feb. 21, 1534) to attaint the friends of Elizabeth Barton (*q.v.*), the "Holy Maid of Kent." Barton turned out to have been an impostor, but she had duped More, and he had given his countenance to her supernatural pretensions. His name, with that of Fisher, was accordingly included in the bill as an accomplice. When he came before the council it was at once apparent that the charge of treason could not be sustained, but he was asked why he had not expressed his approval of the king's attitude towards the papal see. He replied by repeating the substance of conversations with the king on the subject. The revelation was disconcerting, and unlikely to help More's cause in the end. But the charge of treason being too ridiculous to be proceeded with, More's name was struck out of the bill. When his daughter brought him the news, More is reported to have said, "I' faith, Meg, quod differtur, non aufertur: that which is postponed is not dropt."

In March 1534 the bill vesting the crown in Anne Boleyn's issue, and imposing an oath abjuring any foreign potentate and, in the case of clergy, the authority of the pope, was passed and the oath ordered to be tendered. More was sent for to Lambeth, where he offered to swear to the succession, but steadily refused the oath of supremacy as against his conscience. Thereupon he was given in charge to the abbot of Westminster, and, persisting in his refusal, was four days (April 17) afterwards committed to the Tower. More was well treated by his gaolers, and, though he suffered in health from his confinement, he was witty and gay when his family were allowed to visit him, and he wrote cheerfully to his friends. In June 1535 he was found to be in communication with his fellow-prisoner, Fisher. He was then rigorously isolated, and was denied the use of pen and ink. He was brought to trial before a special commission and a picked jury at Westminster Hall on July 1. Rich, the solicitor-general, quitted the bar and presented himself as a witness for the Crown. Being sworn, he detailed a confidential conversation he had had with the prisoner in the Tower. He affirmed that, having himself admitted in the course of this conversation "that there were things which no parliament could do—*e.g.,* no parliament could make a law that God should not be God," More had replied, "No more could the parliament make the king supreme head of the Church." By this act of perjury a verdict of "guilty" was procured.

The execution of the sentence followed within the week, on July 7, 1535. The head was fixed upon London Bridge. Tradition says that it was eventually rescued by his daughter, and that it was buried with her at St. Dunstan's, Canterbury. The vengeance of Henry was not satisfied by this judicial murder of his friend and servant; he enforced the confiscation of what small property More had left, expelled Lady More from the house at Chelsea, and even set aside assignments which had been legally executed by More, who foresaw what would happen before the commission of the alleged treason. More's property was settled on Princess Elizabeth, later queen, who held it till her death.

Sir Thomas More was twice married, but had children only by his first wife, who died about 1511. His only son, John, married an heiress, Ann Cresacre, and was the grandfather of Cresacre More, Sir Thomas More's biographer. His eldest daughter, Margaret (1505–1544), married to William Roper (1496–1578), was a woman of high intelligence, whose devotion to her father has become a legend.

More was lawyer, wit, scholar and a great amateur of the arts. He was an intimate friend of Holbein, whose first introduction to England was as a visitor to More in his house at Chelsea, where the painter is said to have remained for three years and probably first met Henry VIII. Holbein painted portraits of Sir Thomas and his family. More was beatified by Leo XIII. in 1886.

The *Epistola ad Dorpium* exhibits More emphatically on the side of the new learning. It contains a vindication of the study of Greek, and of the desirability of printing the text of the Greek Testament—views which were condemned by the party to which More afterwards attached himself.

In the *Utopia,* published in Latin in 1516 (1st English translation, 1551), More wrote a delightful satire on government and society. In it he relates the conversation of himself and Peter Giles with a fictitious mariner Ralph Hythlodaye, who has sailed with Amerigo Vespucci. Hythlodaye had visited England, and has much to say of the evils of poverty and the luxury of the rich. This description is compared with that of the island of Utopia where community of goods, a national system of education, the rule of work for all, and a philosophy under which the good of the individual is sacrificed to the common good, makes an ideal state. Slavery and monarchy, however, have their place in Utopia. The book derives from Plato, and has had numerous successors, but none more witty and satirical.

For a bibliography of More's numerous works *see* the article in the *Dict. Nat. Biog.* and the Catalogue of the Alfred Cock collection of books and portraits of or relating to Sir Thomas More which is preserved in the Guildhall Library, London. The more important of his works and their editions are here given. *Luciani dialogi . . . complura opuscula ab Erasmo Roterodamo et Thoma Moro . . . traducta* (Paris, 1506 and 1514; Venice, Aldus, 1516, etc.) was accomplished by Erasmus and More in 1505. *The Lyfe of John Picus, earle of Mirandula . . .* printed by Wynkyn de Worde in 1510, translated by More from the Venice ed. of 1498, was edited by J. M. Rigg for the Tudor Library in 1890. *Historie of the pittiful Life and unfortunate Death of Edward the Fifth and the then Duke of York with . . . Richard the Third* was written, according to Rastell, in 1513, and first printed in a corrupt version in Grafton's continuation of Harding in 1543; it is included by Rastell in his 1557 edition of More's *Workes,* but it has been suggested that the Latin original was by Cardinal Morton; as the *History of King Richard III.* it was edited by J. R. Lumby for the Pitt Press in 1883. The *Libellus vere aureus . . .* better known as *Utopia,* was printed at Louvain in 1516, under the superintendence of Erasmus, and appeared in many subsequent editions, the finest being the Basel edition of 1518 produced by the Froben press under the eye of Erasmus and adorned with illustrations by Holbein. It was translated into the chief languages of Europe, and into English by Ralph Robinson as *A fruteful and Pleasaunt Worke of the best State of a Publyque Weale, and of the newe Yle called Utopia* (Abraham Nell, 1551); many modern editions of which the most famous is that produced by William Morris at the Kelmscott Press (1893). Other translations of *Utopia* are by Gilbert Burnet (1684) and by A. Cayley (*Memoirs of More,* 2 vols., 1808). Against Luther and Tyndale Sir T. More wrote *A Dyaloge of Syr Thomas More, Knt.,* written in 1528 and printed by John Rastell in 1529; *Sir Thomas More's Answere to the fyrste parte of the Poyson'd book . . . The Souper of the Lorde* (William Rastell, 1532) with a "Second Parte" in 1533. The *Apologye of Syr Thomas More,* written in 1533, is a defence of his own polemical style and of the treatment of heretics by the clergy. *A Dyaloge of Comfort against Tribulacion,* printed by Rastell in 1533, was destined primarily for More's family.

More's English works were collected by William Rastell and published as *The Worke of Sir Thomas More Knyght* by Cawood, Waly and Tottel in 1557; his Latin works *Thomae Mori . . . Lucubrationes* were partially collected at Basle 1563 and in 1566 (*omnia opera*) at

Louvain; a fuller edition drawn chiefly from these two appeared at Frankfort and Leipzig in 1689. His correspondence with Erasmus is partly included in the editions of the Letters of Erasmus, and much of his correspondence is calendared in Gairdner's *Letters and Papers of Henry VIII.*, the letters written to his family in his last days being found in vol. viii.

The Mirror of Vertue in Worldly Greatness; or, the Life of Syr Thomas More was written by his son-in-law William Roper about the end of Mary's reign. It was preserved in ms. during the reign of Elizabeth, and handed down in copies, many of which were carelessly made. It was not given to the press till 1626, with the date of Paris. Reprints were made by Hearne (Oxford, 1716), by Lewis (1729, 1731), who added an appendix of documents, and by Singer (1817, 1822) and for the King's Library (1902). Roper's *Life* is the source of all the many subsequent biographies. More's *Life* in ms. (Harleian 6253 and elsewhere), anonymous, but by Nicolas Harpsfield, was also written in Mary's reign. All that is material in this ms. is taken from Roper. The preface is signed Ro. Ba. (Robert Barnstaple?). William Rastell's *Life of More*, of which fragments are preserved in the Arundel Coll. (Brit. Mus.), is unhappily, lost. Thomas Stapleton *Tres Thomae, s. res gestae S. Thomae apostoli, S. Thomae archiepiscopi Cantuariensis, Thomae Mori* (Douay, 1588; Cologne, 1612) and the *Vita Thomae Mori* (separately) (Gratz, 1689) translates Roper, interweaving what material he could find scattered through More's works and letters and the notices of him in the writings of his contemporaries. Cresacre More, great-grandson of Sir Thomas, compiled a new life about the year 1627. It was printed at Paris without date, but, according to the editor, J. Hunter, in 1631. The title of this edition is: *The Life and Death of Sir Thos. More, Lord High Chancellour of England*, and with new title-page 1642, 1726, 1828. The later lives of Sir Thomas More have been numerous the best being those by G. T. Rudhart *Thomas Morus, aus den Quellen bearbeitet* (Nuremberg, 1829); by Father T. E. Bridgett, *Life and Writings of Sir Thomas More* (1891); and by W. H. Hutton, *Life and Writings of Sir Thomas More* (1891). Anne Manning's *The Household of Sir Thomas More* (1851, reprinted in King's Novels, 1905) is an attractive reconstruction. The tragedy of *Sir Thomas More*, edited by A. Dyce for the Shakespeare Society in 1844, and connected by some commentators with Shakespeare, was written about 1590, and therefore gives a nearly contemporary view of More. A later playwright, James Hurdis, made More's career the subject of a play in 1792.

MORÉAS, JEAN (1856–1910), French poet, born at Athens, was the grandson of Papadiomontopoulos, one of the heroes of Missolonghi. He was one of the leaders of the symbolist movement in French poetry, but his early volumes of poems, *Les Syrtes* (1884), *Les Cantilènes* (1886), and *Le Pèlerin passionné* (1891) won recognition beyond the limits of this school. In the *XIXe siècle* (Aug. 11, 1885) he formulated the principles of the symbolists, defending them from the appellation of "decadent," and in the literary supplement of the *Figaro* (Sept. 18, 1886) he published a manifesto justifying the innovations of the new school as the natural development of the prosody of Baudelaire, Mallarmé and Verlaine. As time went on he repudiated the licence claimed by the symbolists, and became the leader of an offshoot from the main body known as the *école romane*, the chief members of which were Raymond de la Tailhède, Maurice du Plessys, Ernest Raynaud, and Charles Maurras. Moréas and his new followers returned to the traditional severity of French versification, and to the classical and antique tradition. His later volumes are *Poésies, 1886–1896* (1898), *Stances* (6 vols., complete ed. 1905), indispensable for the student of his work, *Histoire de Jean de Paris, roi de France* (1902), *Voyage en Grèce en 1897* (1902), *Contes de la vieille France* (1903), and a classic drama in verse, *Iphigénie à Aulis* (1904), in close imitation of Euripides, which was presented, Aug. 24, 1903, in the ancient theatre of Orange, and subsequently at the Odéon in Paris. He died March 31, 1910.

See Anatole France, *La Vie littéraire* (4th ser., 1892); A. van Bever and P. Léautaud, *Poètes d'aujourd'hui, 1880–1900* (11th ed., 1905); P. Berthelot, art. "Symbolisme" in *La Grande encyclopédie;* and J. de Gourmont, *Jean Moréas, biographie critique* (1905).

MOREAU, GUSTAVE (1826–1898), French painter, was born in Paris on April 6, 1826. His father was an architect. The only influence which really affected Moreau's development was that of the painter Chassériau (1819–1857). Moreau's first picture was a "Pietà" (1852), now in the cathedral at Angoulême. In the Salon of 1853 he exhibited a "Scene from the Song of Songs" (now in the Dijon Museum) and the "Death of Darius" (in the Moreau Gallery, Paris), both conspicuously under the influence of Chassériau. From that time he exhibited regularly, with an interval in 1869 to 1876. His colour is luminous, like enamel; and his subjects strange and mysterious. Moreau exhibited for the last time at the Salon of 1880, when he contributed "Helen" and "Galatea"; to the Great Exhibition of 1889 he again sent the "Galatea" and "The Young Man and Death." Moreau received many honours and prizes. He succeeded Delaunay as professor at the École des Beaux Arts, and his teaching was highly popular. He died on April 18, 1898, leaving to the state his house, containing about 8,000 pictures, water-colours, cartoons and drawings, which form the Moreau Gallery.

See Ary Renan, *Moreau* (Paris, 1900); Paul Flat, *Le Musée Gustav Moreau* (Paris, 1900); for an appreciation of his art *see* J. K. Huysman's *Certains* (1908).

MOREAU, HEGESIPPE (1810–1838), French lyric poet, was born in Paris. He was habitually homeless, and exposed himself to the dangers of a cholera hospital in the great epidemic of 1832 simply to obtain shelter and food. It was only just before his death that he succeeded in getting his collected poems published, selling the copyright for £4 sterling and 80 copies of the book. This volume, *Myosotis*, was received not unfavourably, but the author's death on Dec. 20, 1838, in a refuge of the destitute, created an excessive interest in it. Moreau's work has a strong note of imitation, especially in his earlier songs, distinguished from those of his model, Béranger, chiefly by their elegiac note.

MOREAU, JEAN VICTOR MARIE (1763–1813), French general, was born at Morlaix in Brittany on Feb. 14, 1763. As a law student at Rennes he formed his fellow-students into an armed band, which took part in daily affrays between the young *noblesse* and populace of the town. He served under Dumouriez with the volunteers of Ille-et-Vilaine, and in 1793 his merits secured his promotion as general of brigade. Carnot promoted him to be general of division early in 1794, and gave him command of the right wing of the army under Pichegru, in Flanders. The battle of Tourcoing established his military fame, and in 1795 he was given the command of the Army of the Rhine-and-Moselle, with which he advanced into Germany. He won several victories and penetrated to the Isar (*see* French Revolutionary Wars), but at last had to retreat before the archduke Charles. The skill he displayed in conducting the retreat greatly enhanced his own reputation; he brought back with him more than 5,000 prisoners. In 1797 after difficulties caused by want of funds and material he again crossed the Rhine, but was checked by the conclusion of the preliminaries of Leoben between Bonaparte and the Austrians. At this time he discovered the correspondence between his old comrade and commander Pichegru and the émigré prince de Condé. Too late to clear himself, he sent the correspondence to Paris and issued a proclamation to the army denouncing Pichegru as a traitor. He was dismissed, and was only re-employed in 1799 when the advance of Suvárov made it necessary. He commanded the Army of Italy for a short time before being appointed to the Army of the Rhine, and remained with Joubert, his successor till the defeat of Novi. Joubert fell in the battle, and Moreau then conducted the retreat of the army to Genoa, where he handed over the command to Championnet. When Bonaparte returned from Egypt he found Moreau at Paris, greatly dissatisfied with the Directory, and obtained his assistance in the *coup d'état* of 18 Brumaire. The First Consul again gave him command of the Army of the Rhine, with which he forced back the Austrians from the Rhine to the Isar. On his return to Paris he married Mlle. Hullot, a creole of Josephine's circle, an ambitious woman who gained a complete ascendancy over him, and after winning the victory of Hohenlinden (Dec. 3, 1800) he settled down to enjoy the fortune he had acquired during his campaigns. His wife collected around her all who were discontented with the aggrandisement of Napoleon. This "club Moreau" annoyed Napoleon, and encouraged the Royalists, but Moreau, though not unwilling to become a military dictator to restore the republic, would be no party to an intrigue for the restoration of Louis XVIII. This was well known to Napoleon, who seized the conspirators. Bonaparte procured Moreau's condemnation with great difficulty, and then treated him with a pretence of leniency, commuting a sentence of

imprisonment to one of banishment. Moreau lived in obscurity for some years at Morrisville, New Jersey, until the destruction of the *grande armée* in Russia. Then, probably at the instigation of his wife, he committed the last and least excusable of his political errors. Negotiations were set on foot with Bernadotte, who, being now crown prince of Sweden and at the head of an army opposing Napoleon, introduced Moreau to the tsar Alexander. In the hope of re-establishing popular government in France, Moreau advised the allied sovereigns on the conduct of the war. He was mortally wounded while talking to the tsar at the battle of Dresden on Aug. 27, 1813, and died on Sept. 2. He was buried at St. Petersburg.

Moreau's fame as a general stands very high; his combinations were skilful and elaborate, his temper always unruffled. He was a sincere republican, though his father was guillotined in the Terror.

See C. Jochmus, *General Moreau—Abriss einer Geschichte seines Lebens und seiner Feldzüge* (1814), a standard work; A. de Beauchamp, *Vie politique, militaire, et privée du Général Moreau* (tr. by Philippart, 1814); Picard, *Bonaparte et Moreau* (1905); and Daudet, *L'exil et la mort du général Moreau* (1909).

MOREAU DE SAINT MÉRY, MEDÉRIC LOUIS ÉLIE (1750–1819), French politician, was born at Fort de France, in the island of Martinique, on Jan. 28, 1750. He came to Paris at the age of 19, and became an *avocat* at the parlement of Paris. He returned to Martinique to practise law, and in 1780 was appointed member of the colonial council of San Domingo. Returning to Paris in 1784, he was commissioned to study the legislation of the French colonies. In 1789 he was president of the assembly of the electors of Paris and represented Martinique in the Constituent Assembly. His moderate ideas caused his arrest after Aug. 10, 1792, but he escaped to the United States, and opened a bookseller's shop at Philadelphia. Returning to France in 1799, he became historiographer to the navy and councillor of state, and drafted in part the colonial and maritime code. In 1802 he was appointed by the first council administrator of the duchies of Parma, Piacenza, and Guastalla, but was dismissed in 1806 and lived until his death on a pension paid him by the Empress Josephine, a kinswoman of his.

He published *Lois et constitutions des colonies françaises de l'Amerique sous le Vent de 1550 à 1785* and *Déscription topographique et politique de la partie espagnole et de la partie française de l'Ile de Saint-Domingue* (1796–98).

See Fournier-Tescay, *Discours prononcé aux obsèques de Moreau le 30 Janvier 1819;* Silvestre, *Notice sur Moreau* (1819).

MORECAMBE, municipal borough, watering place and minor seaport, Lancaster parliamentary division, England, on Morecambe bay, 236 m. N.W. from London by the L.M.S. railway. Pop. (1931) 24,586. A promenade extends along the shore; there are a quay, a pier, and a winter garden. The L.M.S. railway is the harbour authority. The town was incorporated in 1902. The former alternative name was Poulton-le-Sands.

MOREL, the surname of several French classical scholars and printers in the 16th and 17th centuries, known for their editions of classical authors and the Fathers. (1) GUILLAUME MOREL (1505–1564) was born at Tilleul in Normandy. He became king's printer in 1555. His most important work was *Thesaurus vocum omnium latinarum,* containing quotations from Greek authors, taken from hitherto unpublished mss. in the Paris library. (2) FÉDÉRIC MOREL, surnamed the Elder (1523–1583), was born in Champagne. About 1550 he married the daughter of the famous printer, Michel de Vascosan, in 1557 set up in business in the rue Saint Jean de Beauvais, and in 1571 was appointed printer to the king. His chief publications were the *Declamationes* of Quintilian and *L'Architecture de Philibert Delorme.* (3) FÉDÉRIC MOREL, son of the preceding, surnamed the Younger (1558–1630), was one of the greatest Greek scholars of his time. He succeeded to his father's business, and was also professor of eloquence at the Collège de France. Special mention may be made of his revised edition of Amyot's translation of *Plutarch* and his Latin translations of some of the dissertations of Maximus of Tyre, of Libanius, Hierocles and Theodoret. (4) CLAUDE MOREL (1574–1626), brother of the preceding, also published editions of many of the Fathers and other authors. (5) CHARLES MOREL (1602–40) was printer and secretary to the king. He issued the works of Clement of Alexandria, Gregory of Nazianzus, Cyril, Synesius and Chrysostom, and the *Concilia generalia et provincialia* of Severin Bini. (6) GILLES MOREL, brother of the preceding (dates unknown). His chief publication is the *Grande bibliothèque des pères* (17 vols., 1643).

See M. Maittaire, *Historia typographorum aliquot parisiensium* (1717), for all the above; Fédéric Morel the elder is the subject of a monograph by J. Dumoulin (1901).

MOREL (*Morchella esculenta*), an edible fungus of North America and central and southern Europe. The wrinkled pileus (cap), the edible portion, is yellowish-brown and about an inch long. It is chiefly used in gravies and sauces. By many the flavour is considered superior to that of most mushrooms. The morel is an Ascomycete. (*See* FUNGI.)

MORELIA (formerly Valladolid), a city of Mexico and capital of the State of Michoacán, 125 m. direct and 234 m. by rail W. by N. of the city of Mexico, near the southern margin of the great Mexican plateau, 6,398 ft. above sea-level, in lat. 19° 42′ N., long. 100° 54′ W. Pop. (1924) 40,000, partly Indians and mestizos. Morelia is served by a branch of the Mexican National railway; its station is outside the city, with which it is connected by a small tramway line. The city is built on a rocky hill rising from the Guayángareo valley, which gives to it a strikingly picturesque appearance. It has the usual rectangular plan, with several pretty squares and straight, clean, well-paved streets. Facing the *plaza mayor,* now called the Plaza de los Mártires because of the execution there of the patriot Matamoros in 1814, is the cathedral, one of the finest specimens of the old Spanish Renaissance church architecture in Mexico.

Opposite the cathedral is the Government palace, which also contains the public library. The municipal government is housed in an ancient tobacco factory converted to public uses, and a fine old Capuchin convent now serves as a public hospital. The Paseo, or public park, is distinguished for its fine trees and flowers. The Morelianos are noted for their love of music, and musical competitions are held each year, the best band being sent to the city of Mexico to compete with similar organizations from other States. The public water-supply is brought into the city over a fine old aqueduct (3 m. in length, carried on arches), which was built in 1785 by the bishop of the diocese as a famine relief work. Like the rest of Michoacán, Morelia is a stronghold of clericalism and conservatism. Its manufactures include cotton, woollen and silk textiles, cigars and cigarettes, and *dulces,* or sweetmeats, notably a variety called *Guayabate.*

Morelia, first known as Valladolid, was founded in 1541 by Viceroy Mendoza. In 1582 Valladolid replaced Patzcuaro as the capital of Michoacán. It was the birthplace of both Morelos and Itúrbide, and was captured by Hidalgo at the beginning of the revolutionary outbreak of 1810–11, and by Itúrbide in 1821 when on his march to Mexico City. Its name was changed in 1828, in honour of the revolutionary leader José Maria Morelos y Pavón, and in 1863 it was made the see of an archbishop.

MOREL-LADEUIL, LÉONARD (1820–1888), French goldsmith and sculptor, was born at Clermont-Ferrand in 1820, and died at Boulogne on March 15, 1888. He was apprenticed first to Morel, a manufacturer of bronzes, under whom he became one of the most expert chasers, or *ciseleurs,* in France, and then to Antoine Vechte, to acquire the art of *repoussé* (*q.v.*)—the art in which he was to excel. He studied further under J. J. Feuchère and was commissioned by the French Government to produce the "Empire Shield." The trade, annoyed that a craftsman should obtain commissions direct, thenceforward boycotted the young artist. He was encouraged nevertheless by a foreign dealer in Paris, Marchi, who employed him on statuettes, until 1859, when Messrs. Elkington engaged him to work in Birmingham in *repoussé,* assuring him a free hand. His beautiful plateau called "Dreams," was subscribed for by Birmingham as the town wedding-gift to the prince and princess of Wales. Morel-Ladeuil remained with the firm for twenty-three years, the first result being his masterpiece the "Milton Shield: Paradise Lost" (in *repoussé* steel and silver), which was bought by the English Government

for £3,000. His "Helicon Vase," in steel, silver and gold, priced at £6,000, was presented by the ladies and gentlemen of the royal house to Queen Victoria on her first jubilee. His total work, apart from the productions of his youth, numbers 35 pieces.

See *L'Oeuvre de Morel-Ladeuil, sculpteur-ciseleur,* by L. Morel (Paris, 1904).

MORELLET, ANDRE (1727–1819), French economist, miscellaneous writer and academician (1785), was born at Lyons. He was educated by the Jesuits in his native town, and at the Sorbonne; he then took holy orders, but his designation of abbé was the chief thing clerical about him. He had a ready and biting wit, and Voltaire called him "L'Abbé Mord-les." A year before his death in Paris (Jan. 12, 1819) he brought out four volumes of *Mélanges de littérature et de philosophie du XVIIIe siècle,* composed chiefly of selections from his former publications. His valuable *Mémoires sur le XVIIIe siècle et la Révolution* (2 vols., 1821), appeared posthumously.

A bibliography of his numerous works is given in Quérard's *La France littéraire,* vol. vi.; *see* also Sainte-Beuve, *Causeries du lundi,* vol. i.

MORELLI, GIOVANNI (1816–1891), Italian patriot and art critic, born at Verona on Feb. 16, 1816, was educated first at Bergamo and then at Aarau in Switzerland. At 18 he commenced his university career at Munich, being debarred as a Protestant from entering any Italian college, and became the pupil of Ignatius Döllinger, the celebrated professor of anatomy and physiology. He specially devoted himself to natural philosophy and medicine but was also keenly interested in all scientific and literary pursuits. His brilliant gifts and independence of thought and judgment attracted the attention of the most distinguished men of the day. In Paris his intimacy with Otto Mündler was not without its effect in determining the direction of his future studies; and while in Switzerland, he formed a friendship with Louis Agassiz, whose teaching made a lasting impression upon him. On his return to Italy in 1840 he became associated in Florence with the patriots who were working for the deliverance of their country from Austrian rule. He took part in the war of 1848, and was chosen by the provisional Lombard government to plead the cause of Italian unity before the German parliament.

In 1860 Victor Emmanuel named Morelli a citizen of the Sardinian kingdom, and in the next year he was elected deputy for Bergamo to the first free Italian parliament. He was a staunch supporter of Cavour, and exercised a considerable influence over the most prominent statesmen of the Right, who valued his sound judgment, integrity, moderation and foresight. After his election he drew the attention of parliament to the urgent need of reform in the administration of matters relating to the fine arts and a commission was appointed to bring under government control all works of art which could be considered public property. The commission, of which Morelli was president, began its work in Umbria and the Marches, and he appointed as his secretary G. B. Cavalcaselle, who was then engaged in collecting materials for a work on Italian art. Much that Cavalcaselle then learned from his chief was embodied in the well-known *History of Painting,* published in 1864 in conjunction with Sir Joseph Crowe.

The immediate result of Morelli's first labours in the Marches was an enactment, which bears his name, prohibiting the sale of works of art from public and religious institutions. In 1873 he became a senator of the kingdom of Italy, having voluntarily resigned his seat in the Lower House owing to the increasingly democratic tendencies of the Chamber. In Milan, his home, he published some of his researches into the history of Italian art. In order to be free to speak his mind unreservedly, he adopted a pseudonym and wrote in German. His first contributions, a series of articles on the Borghese gallery, were published in Lützow's *Zeitschrift für bildende Kunst* (1874–76). Posing as an art-loving Russian, he adopted the pseudonym of Ivan Lermolieff—an anagram of his own name with a Russian termination—and described his essays as *Ein kritischer Versuch,* translated from the Russian by Johannes Schwarze—a Germanized form of Morelli.

In 1880 Morelli published under the same pseudonym, *Die Werke italienischer Meister in den Galerien von München, Dresden und Berlin,* which inaugurated a new and more scientific method of criticism, and marks an epoch in the art studies of the 19th century. The book was translated into English in 1883, with Morelli's own name upon the title-page, a few years later into Italian. A volume of *Critical Studies,* first of a series of three which, under the title of *Kunstkritische Studien,* was to contain all Morelli's contributions to art literature, was published in 1890. The first part, cast in dialogue form, contains a detailed exposition of his method. Then follow *The Borghese Gallery,* a reissue of his former articles with many important additions, and *The Doria Gallery,* an entirely new contribution. The second volume deals with the galleries of Munich and Dresden, and is a revised edition of the first two parts of the original book of 1880; but here again copious additions rendered it practically a new book. The third volume was to treat of the Berlin gallery, and was also to contain an exhaustive account of the drawings of Italian masters, but it was not carried out. Morelli was taken seriously ill in Feb. 1891 and died at Milan on Feb. 28.

MORELLI'S METHODS

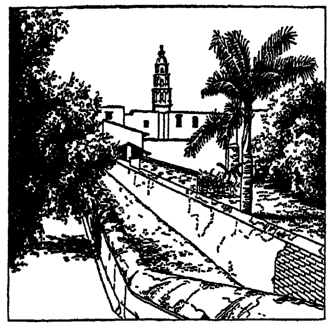
Morelli found art criticism uninspired, unscientific and practically worthless. To be of any real value he held that historical, documentary and traditional knowledge respecting works of art was only of secondary importance as compared with the evidence to be derived from the study of the pictures themselves. He contended that art criticism must be conducted on scientific principles and follow a strict course of inductive reasoning. A painting should be subjected to a searching analysis, and each of its component parts and minutest details to methodical investigation.

Studying one day in the Uffizi, it suddenly struck him that in a picture by Botticelli containing several figures the drawing of the hands was remarkably similar in all; that the same characteristic but plebeian type, with bony fingers, broad square nails, and dark outlines, was repeated in every figure. Turning to the ears, he observed that they also were drawn in an individual manner. Then he examined other works by this painter, and found that the same forms were exactly repeated, together with other individual traits which seemed distinctive of the master: the characteristic type of head and expression, the drawing of the nostrils, the vitality of movement, the disposition of drapery, harmony of colour (where it had not been tampered with by the restorer), and quality of landscape.

In all Botticelli's true works the presence of these and other characteristics proclaimed their genuineness. In paintings where the forms and types were those of the painter, but where vitality, movement, and all deeper qualities were absent, Morelli recognized works executed from the master's cartoons; while in pictures where neither types nor forms responded to the test, and where only a general family likeness connected them with Botticelli, he discerned the productions of pupils and imitators. After applying his method to the works of Botticelli, he examined those of other Florentine masters, and afterwards of painters of other Italian schools, everywhere meeting with results to him not less convincing. If the drawing of the hand and ear were not always conspicuous, there were other peculiarities of this language of form to aid in the identification of a master: the treatment of the hair, as in Piero dei Franceschi; the indication of the sinews, as in Foppa; the drawing of the eye, as in Liberale da Verona; the modelling of the eyelid and upper lip, as in Ambrogio de Predis; the form of the feet, as in Luini. In short, all apparently insignificant details were of importance in his plan of study, for to him they were like the signature of the master. (C. J. Ff.; X.)

MORELOS, an inland State of Mexico on the southern slope of the great Mexican plateau, lying south of the Federal District, with the States of Puebla on the east and south-east, Guerrero on the south, and Mexico on the west, north and north-east. Pop. (1921) 103,440, including a large percentage of Indians and mixed bloods. Area 2,773 sq. miles. Its surface is roughly broken by mountain ranges extending southward from the Sierra de Ajusco, forming many valleys opening southward. It is drained by the Amacusac river, a northern tributary of the Mescala, or Balsas. There is a wide variation of climate for so small a territory, the

higher elevations of the Sierra de Ajusco being cold and humid (the Mexican Central crosses the range at an elevation of 9,974 ft.); the lower spurs mild, temperate and healthy, the lower valleys sub-tropical, hot and unhealthy. The rainfall is light in the lower regions and irrigation is generally employed. Morelos is one of the most flourishing agricultural States of Mexico, producing sugar, rice, Indian corn, coffee, wheat, fruit and vegetables. Although the State is supposed to have several of the minerals found in this part of Mexico (silver, cinnabar, iron, lead, gold, petroleum and coal), its mining industries continue undeveloped and neglected.



BY COURTESY OF THOMAS F. LEE

A WHITE-WALLED STREET IN THE CITY OF CUERNAVACA, CAPITAL OF MORELOS

After the capital, Cuernavaca, the largest city in the State is Cuautla Morelos, or Ciudad Morelos (pop. 4,462 in 1921), 27 m. east by south of Cuernavaca, on the Interoceanic railway, and in a rich sugar-producing district; it has large, modern sugar mills. There are hot sulphur springs here. The town is celebrated in Mexican history for the intrepid defence of the place by José Maria Morelos (1765–1815), the patriot leader, against a greatly superior royalist force, from Feb. 19, to May 2, 1812, when he cut his way through the attacking army and escaped. Other important towns are Yautepec (2,537 in 1921), 16 m. east of Cuernavaca, on the Interoceanic line; Tetecala, 13 m. south-west of the capital, a characteristic Indian town near the pyramid of Xochicalco, and Jojutla, 21 m. south of the capital, on the Interoceanic railway near the southern boundary of the State. Lake Tequesquiten was formed by the subsidence of a large area about the middle of the 19th century, carrying with it an old town. The spire of the old church is still seen in the middle of the lake.

MOREPORK, the name given to two birds, from a fancied resemblance of their calls to these words. One is the Australian species of frogmouth (*q.v.*), related to the goatsuckers and nighthawks. The other is a small brown owl of New Zealand (*Spiloglaux novae-zealandiae*), still fairly common, which haunts the clumps of Maori bush and calls in the twilight. Maori names for this owl are *ruru* and *koukou,* both being attempts to turn his cry into words; he plays a lively part in Maori bird lore.

MORESNET, a small area of Belgium on the German border, 4 m. S.W. of Aix-la-Chapelle. *See* EUPEN and MALMÉDY.

MORETON BAY CHESTNUT or **AUSTRALIAN CHESTNUT,** a tall tree known botanically as *Castanospermum australe* (family Leguminosae), native of Queensland and New South Wales. The pods are almost cylindrical, about 9 in. long and 2 in. broad, and are divided interiorly by a spongy substance into three to five cells, each of which contains a large chestnut-like seed. The seeds are roasted and eaten by the natives; the timber, which somewhat resembles walnut, is soft, fine-grained, and takes a good polish, but is not durable.

MORETO Y CAVAÑA, AGUSTIN (1618–1669), Spanish dramatist and brilliant plagiarist. His adaptations are remarkable for their charm and skill; the most celebrated is *El Desdén con el Desdén,* whose episodes are taken from four separate plays of Lope de Vega.

MORETTO, IL (1494–1554), Italian painter of the Brescian school. His real name was Alessandro Bonvicino. He was probably born at Brescia, and was a pupil of Fiorante Ferramola, a Brescian follower of Foppa. It has been said that Moretto's works display the influence of Titian, of Raphael, and of other contemporary masters. He was, however, a strong individuality with a distinctive style of his own. His conception of form was strong and elegant; his sense for colour harmonious and decorative. His compositions are bathed in a cool, silvery tone, his figures are modelled by a fine play of light and shade. As a portraitist he went beyond the rendering of external form, penetrating into the character and disposition of his sitters. He worked chiefly in Brescia, where his paintings can best be studied. In 1529 he was in Bergamo; in 1540–41 in Milan and Verona. He died at Brescia on Dec. 29, 1554.

His earliest picture, dated 1518, is the "Christ bearing the Cross," at the Town gallery of Bergamo; the frescoes in the Corpus Domini chapel of San Giovanni Evangelista at Brescia are dated 1521. In the decoration of this chapel he collaborated with Romanino, another leading painter of Brescia. Among his first paintings are the ceiling fresco representing the "Vision of Moses," and other paintings in the Galleria Martenengo at Brescia. The churches of Brescia possess many altar pieces by him, among which the "Coronation of the Virgin," in San Nazzaro e Celso, is perhaps the most notable. In the church of Paitone, near Brescia, is "The Virgin appearing to a Shepherd Boy." There is a large, well-composed picture representing "Christ in the house of Levi" in the nuns' gallery of Santa Maria della Pieta in Venice, dated 1544. The Vienna gallery has a "St. Justina," perhaps his finest work. The National Gallery, London, has three fine portraits and several other works, the Johnson collection in Philadelphia a "Madonna and Donors"; the Metropolitan Museum of Art at New York a "Christ in the Desert," a charming early work, and an "Entombment," dated 1554, which is his latest known work. His foremost pupil was the famous portrait painter Giambattista Moroni.

See Crowe and Cavalcaselle, *History of Painting in North Italy* (2nd ed. 1912); G. Morelli, *Italian Masters in German Galleries* (1883); S. Fenaroli, *Alessandro Bonvicino* (1875). (I. A. R.)

MORET Y PRENDERGAST, SEGISMUNDO (1838–1913), Spanish politician, was born at Cadiz on June 2, 1838. He was educated at the Central University, Madrid, and became professor of political economy there. In 1863 he entered the Cortes as a Liberal, took part in the revolution of 1868 and in the constituent assembly of 1869. Colonial secretary in 1870 under General Prim, and later finance minister, he was for a few months in 1872 Spanish ambassador to Great Britain, and after resigning this post accepted the directorship of a large London bank. A year later he returned to Spain. He re-entered Parliament in 1879, and helped to found the Democratic dynastic party. He was minister for foreign affairs under Sagasta in 1885 and again in 1893–4, minister of the interior 1885–8, and minister of colonies 1897. In this capacity he advocated the grant of autonomy to Cuba and Porto Rico, and was opposed to the war with America of 1898. He was Prime Minister in 1905–6 and again in 1909, and at the time of his death in Madrid on Jan. 28, 1913, was president of the Chamber.

MORGAGNI, GIOVANNI BATTISTA (1682–1771), Italian anatomist, was born on Feb. 25, 1682 at Forlì. After graduating in 1701 at Bologna in philosophy and medicine, he acted as prosector to A. M. Valsalva (one of the distinguished pupils of Malpighi), whom he assisted in preparing his celebrated *Anatomy and Diseases of the Ear* (1704). When Valsalva was transferred to Parma, Morgagni succeeded to his anatomical demonstratorship, but after a time gave up his post and spent two or three years at Padua, where in 1710 he succeeded his friend, Domenico Guglielmini, as professor of medicine. In 1715 he was promoted to the chair of anatomy in which he enjoyed a stipend that was increased from time to time by vote of the senate until it reached 1,200 gold ducats. He was honoured by various academies, by cardinals and popes, and was elected patron of the German students of the university. Morgagni died at Padua on Dec. 6, 1771.

Although his *Adversaria anatomica* (1706–19) had established his reputation as an accurate anatomist, it was not until 1761, when he was in his eightieth year, that he brought out the great work which made pathological anatomy a science, and diverted the course of medicine into new channels of exactness—the *De Sedibus et causis morborum per anatomem indagatis* (often reprinted, Eng. trs. 1769). It treats of the morbid conditions of the body *a capite ad calcem,* and contains records of some 640 dissections, the symptoms during the course of the malady and other antecedent circumstances being always prefixed with more or less fullness. Although he was the first to demonstrate the absolute necessity of basing diagnosis, prognosis and treatment on a

comprehensive knowledge of anatomical conditions, he made no attempt to exalt pathological anatomy into a science disconnected from clinical medicine and remote from practical needs.

BIBLIOGRAPHY.—Morgagni's collected works were published at Venice in 5 vols. in 1765. His biography was published by Mosca at Naples in 1768. *See* also prefix to Tissot's 1779 edition of the *De Sensibus.*

MORGAN, ARTHUR ERNEST (1878–), American engineer and college president, was born at Cincinnati (O.), on June 20, 1878. He received his early education in the high school at St. Cloud (Minn.), and then spent three years in Colorado in various occupations, including a short term at the University of Colorado. Returning to Minnesota, he worked for his father, a land surveyor, and studied engineering at night. In 1902 he commenced to practise for himself at St. Cloud, making a special study of floods and flood control. In 1907 he became supervising engineer of U. S. Government drainage investigations, but in 1909 founded the Morgan Engineering Company, of which he became president. His firm undertook many reclamation projects in the southern States. In 1921 he was appointed president of Antioch college, Yellow Springs (O.), which was reorganized under his inspiration. (*See* ANTIOCH COLLEGE.) He was the author, among other works, chiefly technical, of *The Miami Valley and the 1913 Flood* (1917) and of *My World* (1927), an expansion of a syllabus used for some years in classes at Antioch college.

MORGAN, DANIEL (1736–1802), American soldier, was born in Hunterdon county, N.J., in 1736, of Welsh ancestry. In 1753 he removed to Virginia. In June, 1775, soon after the outbreak of the War of Independence, he was commissioned a captain of Virginia riflemen. In the winter of 1775 he accompanied Gen. Benedict Arnold to Canada, and in the assault on Quebec (Dec. 31) he and his riflemen penetrated well into the city, where he was hemmed in and was forced to surrender. Late in 1776 he was released, and soon after commissioned colonel. In Sept. 1777 he joined Gen. Horatio Gates, then engaged in the campaign against Gen. Burgoyne, and took part in both battles of Saratoga. In July, 1779, he resigned from the army and retired to Virginia. After the battle of Camden, however, he joined Gates at Hillsborough, N.C., took command of a corps, and was made brigadier general. In Jan., 1781 Cornwallis and Tarleton attempted to entrap him, but at Cowpens (Jan. 17) he defeated Tarleton and then escaped from Cornwallis into North Carolina. In Nov. 1794 he commanded troops sent to suppress the Whisky Insurrection in western Pennsylvania. He was a Federalist representative in Congress in 1797–99, and died in Winchester, Va., July 6, 1802.

See James Graham, *The Life of General Daniel Morgan of the Virginia Line* (1856); and Rebecca McConkey, *The Hero of Cowpens* (New York, 1885).

MORGAN, SIR HENRY (*c.* 1635–1688), Welsh buccaneer, and lieutenant-governor of Jamaica, is said to have been kidnapped as a boy at Bristol and sold as a slave at Barbadoes, thence making his way to Jamaica, and is possibly to be identified with the Captain Morgan who accompanied the expedition of John Morris and Jackman when Vildemos, Trujillo and Granada were taken. In 1666 he commanded a ship in Edward Mansfield's expedition which seized the island of Providence or Santa Catalina, and shortly afterwards was chosen by the buccaneers as their "admiral." In 1668 he was commissioned by Sir Thomas Modyford, the governor of Jamaica, to capture some Spanish prisoners, in order to discover details of the threatened attack on Jamaica. He took Puerto Principe, Porto Bello on the mainland, and collected a large sum from the governor of Panama. Entrusted with another expedition by Modyford against the Spaniards, he ravaged the coast of Cuba, and in 1669 sacked Maracaibo, and afterwards Gibraltar. Returning to Maracaibo, he found three Spanish ships waiting to intercept him; but these he destroyed or captured, recovered a considerable amount of treasure from one which had sunk, and exacted a heavy ransom for evacuating the place.

On his return to Jamaica a new commission was given to Morgan, as commander-in-chief of all the ships of war in Jamaica, to levy war on the Spaniards. He recaptured the island of Santa Catalina in Dec. 1670, and in 1671 took Panama. Meanwhile on July 8, 1670, a treaty had been signed between Spain and England, and both Modyford and Morgan were ordered home under arrest to answer for their conduct. Morgan, however, soon gained the king's favour, and in 1674 was appointed lieutenant-governor of Jamaica and was knighted, leaving England in December. He was charged by Lord Vaughan, afterwards earl of Carbery, the governor, soon after his appointment, of encouraging privateering; he intrigued against his colleagues and successive governors of Jamaica, and participated in various drunken orgies. Finally, on Oct. 12, 1683, he was suspended in Jamaica from all his employments. He died in Aug. 1688.

See A. O. Exquemelin (one of Morgan's buccaneers), *Buccaneers of America* (1684, reprinted 1891); A. Morgan, *History of the Family of Morgan* (1901); J. L. Phillips, *Sir Henry Morgan* (1912).

MORGAN, JOHN HUNT (1825–1864), American Confederate soldier, was born in Huntsville, Ala., on June 1, 1825, and was brought up near Lexington, Ky. In the Mexican War he was a first lieutenant of a cavalry regiment. On the outbreak of the Civil War he joined the Confederate army and, being an able scout, was made commander of a cavalry squadron. He was commissioned a colonel after the battle of Shiloh, and in July 1862 made the first of his famous raids, threatening Louisville and Cincinnati. In August and September he took part in General Braxton Bragg's invasion of Kentucky, and again threatened Ohio. In December he defeated the Union garrison at Hartsville, Tenn., was commissioned brig.-general for this success, and soon afterward again raided Kentucky. To cover Bragg's movement from Tullahoma to Chattanooga Morgan made, in July 1863, his raid into Indiana and through Ohio, though Bragg had instructed him to confine himself to Kentucky. With 2,460 men he crossed the Cumberland, near Burkesville, Ky., on July 2; on the 5th he captured a garrison at Lebanon, and on the 13th entered Ohio near Harrison. The regular cavalry was now close behind him. He marched through the suburbs of Cincinnati on the night of the 13th and on the 18th reached Portland, near Buffington island, where in a sharp battle he lost 600 or more men, and as many more surrendered. On the 26th he surrendered to General Shackelford at New Lisbon. He was imprisoned in the penitentiary at Columbus, from which on the night of Nov. 27 he escaped. In the spring of 1864 he was put in virtual command of the department of south-western Virginia, and late in August he took command at Jonesboro, Ga. On Sept. 4 he was shot in a garden in Greenville, Tenn., having been betrayed, it appears, to the Federals.

See Basil W. Duke, *History of Morgan's Cavalry* (1867).

MORGAN, JOHN PIERPONT (1837–1913), American financier and banker, was born in Hartford, Conn., on April 17, 1837, a son of Junius Spencer Morgan (1813–90), who was a partner of George Peabody and the founder of the house of J. S. Morgan and Co. in London. He was educated at the English High school in Boston and at the University of Göttingen. In 1857–60 he worked in the New York banking house of Duncan, Sherman and Co.; from 1860 to 1864 was agent and attorney in New York for George Peabody and Co. of London, and afterwards for its successor, J. S. Morgan and Co., of which he became head; in 1864–71 was a member of the firm of Dabney, Morgan and Co., and in 1871 he entered the firm of Drexel, Morgan and Co., which, in 1895, became the firm of J. P. Morgan and Company.

This firm, which was closely associated with Drexel and Co. of Philadelphia, Morgan, Harjes and Co. (successors to Drexel, Harjes and Co.) of Paris, and Morgan, Grenfell and Co. (before 1910 J. S. Morgan and Co.) of London, became, largely through Morgan's ability, one of the most powerful banking houses in the world. It carried through the formation of the United States Steel Corporation, harmonized the coal and railway interests of Pennsylvania, and purchased the Leyland line of Atlantic steamships and other British lines in 1902, thus effecting an Atlantic shipping "combine" (*see* STEAMSHIP LINES); and it, or the banking houses which it succeeded, reorganized numerous railways including the Chesapeake and Ohio; the Erie and the Reading; the Northern Pacific; and the Baltimore and Ohio. In 1895 the banking house of J. P. Morgan and Company supplied

the United States Government with $62,000,000 in gold to restore the Treasury gold reserve to $100,000,000. Morgan was an enthusiastic yachtsman, whose "Columbia" defeated the "Shamrock" in 1899 and 1901 for the "America's" cup; a notable collector of books, pictures and other art objects, many of which he gave to the Metropolitan Museum of Art (of which he was president); and a generous benefactor of the American Museum of Natural History, the Metropolitan Museum of Art, Harvard university (especially its medical school), the Lying-in hospital of the city of New York and the New York trade schools. He died in Rome March 31, 1913.

His will provided that after the distribution of enumerated bequests amounting to about $17,000,000, chiefly to his family, the residue of his estate should pass to his son, John Pierpont Morgan. In 1916 the estate was finally appraised at $69,449,732. He left only some $700,000 to charities; but while living he had been a generous giver, and in his will suggested that his son continue certain accustomed annual contributions. His works of art and books were left to his son without restrictions, although in his will he said: "It has been my desire and intention to make some suitable disposition of them or of such portion of them as I might determine, which would render them permanently available for the instruction and pleasure of the American people." In the summer of 1913 most of the art collection was placed as a loan exhibit in the Metropolitan Museum of Art, New York city. Later, some items, mostly replaceable, were sold. The remainder, consisting of over 3,000 pieces, was presented to the museum by the son in Dec. 1917, and a new wing was added to the building to house them permanently. This was opened in June 1918. This collection covered all periods and included matchless bronzes, enamels, porcelains and tapestries. The library (dedicated by the son by public charter in 1923 as an institution of research for scholars and provided with liberal endowment, in memory of his father) was appraised at $7,500,000, and consisted of about 25,000 vol. of illuminated manuscripts, early printed books, examples from famous presses and association copies.

MORGAN, JOHN PIERPONT, JR. (1867–), son of John Pierpont Morgan (1837–1913), succeeded his father and continued as active head of J. P. Morgan and Company, and of its associated banking-houses in Philadelphia, London and Paris. He was born at Irvington, N.Y., on Sept. 7, 1867, prepared for college at St. Paul's school and graduated from Harvard in 1889. He received the honorary degree of LL.D. from Cambridge university in 1919 and from Harvard in 1923. In 1891 he became a member of the firm of which his father was the head, and later spent eight years with the London house of J. S. Morgan and Company, now Morgan, Grenfell and Company. Within 16 months after Morgan succeeded his father in 1913 as head of the house, the World War began. Almost immediately the finance department of the City of New York became confronted with a grave situation. Owing to the dislocation of the foreign exchanges, the City of New York found itself unable to meet its obligations maturing in London and Paris, aggregating upwards of $80,000,000. Thereupon Morgan organized a successful bankers' syndicate for $100,000,000 gold, through the operation of which the city's credit was maintained intact.

Within a year the British Government, followed by the French Government, enlisted the services of Morgan and his partners to undertake the work of co-ordinating and finally purchasing in the United States their all-important supplies of foodstuffs and munitions. The purchases which the firm made for the British and French Governments aggregated several billion dollars, and the work which the Morgan firm accomplished in organizing sources of industrial supply in America proved of great service to the U.S. Government when, two years later, in 1917, it undertook to secure its supplies upon a huge scale for the prosecution of its part in the war. Before America's entry into the war, Morgan undertook the work of financing a great part of the Allies' requirements for credits in the United States, and prior to April 1917 had arranged total loan issues to the British and French Governments of $1,550,000,000. During the period of world reconstruction following the war, Morgan continued active; the loans to Great Britain, France, Belgium, Italy, Austria, Switzerland, Japan, Argentina, Australia, Cuba, Canada and to Germany under the Dawes Plan, issued by the firm of J. P. Morgan and Company, aggregated between April 1917 and April 1926 approximately $1,700,000,000. During America's participation in the war Morgan served as a member of the Liberty Loan and other important committees. For five years he was a member of the advisory council of the Federal Reserve Board. In 1922, at the request of the reparations committee, he served at Paris upon a committee of bankers whose report, laying down the essentials of the German reparations problem, was an important preliminary to the work of the Dawes committee two years later. In 1929 he served as an unofficial American delegate at the conference of experts which opened in Paris on Feb. 9 with the hope of making a final and definite settlement of the reparations problem.

In 1920 Morgan presented his residence at Prince's Gate, in London, to the U.S. Government for an embassy. In 1923, by public charter, he dedicated his father's library (to which he had made important additions) as an institution of research for scholars, at the same time providing liberal endowment for it.

MORGAN, LEWIS HENRY (1818–1881), American ethnologist, was born near Aurora (N.Y.) on Nov. 21, 1818. He graduated in 1840 from Union college, and was admitted to the bar and practised at Rochester (N.Y.). His interest in the Iroquois tribe led him to live among them, studying their social organization. In Oct. 1847 he was formally adopted into the Hawk clan of the Seneca tribe, and received the name "Ta-ya-da-o-wub-Rub." The fruit of his researches was *The League of the Iroquois* (1851; new ed. 1904 and 1922). The success of the book encouraged him to further research, resulting in his *Systems of Consanguinity and Affinity of the Human Family* (1869). In 1877 he added to his reputation by publishing *Ancient Society, or Researches in the Lines of Human Progress from Savagery, through Barbarism, to Civilization.* Morgan was a member of the New York assembly in 1861 and of the New York senate in 1868–69. In 1880 he was president of the American Association for the Advancement of Science. He died in Rochester (N.Y.) on Dec. 17, 1881. In addition to the works above mentioned, he published *The American Beaver and his Works* (1868), and *Houses and House-life of the American Aborigines* (1881).

See W. H. Holmes' *Biographical Memoir of L. H. Morgan* (1908).

MORGAN (SYDNEY) LADY (*c.* 1783–1859), Irish novelist, daughter of Robert Owenson, an actor, was born in 1783, in Dublin. She was one of the most vivid and hotly discussed literary figures of her generation. She began her career with a precocious volume of poems. Her *St. Clair* (1804), a novel of ill-judged marriage, ill-starred love, and impassioned nature-worship, in which the influence of Goethe and Rousseau was apparent, at once attracted attention. But the book which made her reputation was *The Wild Irish Girl* (1806), in which she appeared as the ardent champion of her native country, a politician rather than a novelist, extolling the beauty of Irish scenery, the richness of the natural wealth of Ireland, and the noble traditions of its early history. She was known in Catholic and Liberal circles by the name of her heroine "Glorvina." Sydney Owenson entered the household of the marquess of Abercorn, and in 1812, persuaded by Lady Abercorn, she married the surgeon to the household, Thomas Charles Morgan, afterwards knighted, but books still continued to flow from her facile pen. In 1814 she produced her best novel, *O'Donnell.* She was at her best in her descriptions of the poorer classes, of whom she had a thorough knowledge. Her elaborate study (1817) of *France* under the Bourbon restoration was attacked with outrageous fury in the *Quarterly,* the authoress being accused of Jacobinism, falsehood, licentiousness and impiety. She took her revenge indirectly in the novel of *Florence Macarthy* (1818), in which a *Quarterly* reviewer, Con Crawley, is insulted with supreme feminine ingenuity.

Of her many other works may be mentioned *Passages from my Autobiography* (1859). She died on April 14, 1859.

Her autobiography and many interesting letters were edited with a memoir by W. Hepworth Dixon in 1862.

MORGAN, THOMAS HUNT (1866–), American biologist, was born at Lexington, Ky., on Sept. 25, 1866, and educated at the State college of Kentucky and Johns Hopkins university (Ph.D., 1890). In 1891 he became associate professor and in 1894 professor of biology at Bryn Mawr college. In 1904 he was appointed professor of experimental zoology at Columbia university. There, in co-operation with his pupils, he carried on a long series of experimental studies in the laws and mechanism of heredity which resulted in theoretical contributions of first importance to the subject. His observations formed the basis for a complicated theory of paired elements, "factors" or "genes," within the chromosome which are responsible for hereditary unit characters of the individual. The nature of these genes, their arrangement within the chromosome, their relations with each other, and their behaviour in normal inheritance as well as in mutation cases constitute the chief subjects of his research. His observations and conclusions are published in various scientific journals and in his books, which include: *Development of the Frog's Egg* (1887); *Regeneration* (1901); *Evolution and Adaptation* (1903); *Experimental Zoology* (1907); *Heredity and Sex* (1913); *Mechanism of Mendelian Heredity* (1915); *The Physical Basis of Heredity* (1919); *Evolution and Genetics* (1925); *The Theory of the Gene* (1926); *Experimental Embryology* (1927).

MORGANATIC MARRIAGE, a form of marriage in which the contracting parties are not by birth of equal status or rank, and under which the wife, if not of equal rank, does not take the rank of her husband, and the children, whether it be the wife or husband that is of lower rank, have no right of succession to the dignities, fiefs or entailed property of the parent of higher rank. Marriage in this form was properly peculiar to the German peoples, from whom it was adopted by the royal families of other countries. Equality by birth (*Ebenbürtigkeit*) was formerly throughout Germany the necessary condition to a complete and perfect marriage, but in more recent times it was applicable only to members of reigning or "mediatized" houses. In the constitution of the various states, and in the "house laws" (*Hausgesetze*) of the reigning families, the rules were laid down as to what constituted *Ebenbürtigkeit*. In Great Britain the regulations as to the marriages of members of the royal family are contained in the Royal Marriage act 1772 (*see* Marriage). The term "morganatic marriage" is applied generally to any marriage of a person of royal blood with one of inferior rank. Such marriages are recognized as fully binding by the church, the children are legitimate, and no other marriage can take place during the lifetime of the contracting parties.

MORGAN CITY, a city of St. Mary parish, Louisiana, U.S.A., 80 m. W.S.W. of New Orleans, on the Atchafalaya river, Federal highway 90, and the Southern Pacific railway. Pop. 5,429 in 1920; 5,985, 1930. It is the centre of the muskrat-raising district of the state, and has a large fish and oyster industry, a stone crusher making railroad ballast, box factories, saw and planing mills and other manufacturing plants. Its water-borne commerce (all domestic) amounted in 1925 to 777,211 tons, valued at $2,638,568. The city was founded in 1856 and incorporated in 1860 as Brashear City, adopting its present name in 1878.

MORGANTOWN, a city of West Virginia, U.S.A., the county seat of Monongalia county; on the Monongahela river and Federal highways 19 and 119, at an altitude of 825 ft., 100 m. S. of Pittsburgh. It is served by the Baltimore and Ohio and the Monongahela railways and river steamers. The population was 12,127 in 1920 (90% native white) and was 16,186 in 1930 by the Federal census. It is the seat of West Virginia university (established 1867), which has a 50 ac. campus on the river, farms of 700 ac. a mile distant, and an enrollment in 1926–27 of 3,849 students at Morgantown, with 1,205 more in extension courses given in various mining towns and industrial communities throughout the state. Morgantown is a coal-mining centre and has various manufactures (especially cut glass, wire glass, window glass and watch crystals), with an output in 1925 valued at $3,739,916. The city was founded in 1768 by David and Zackwill Morgan. It was incorporated as a town in 1785, and chartered as a city in 1905, after the annexation of Greenmont, Seneca and South Morgantown.

MORGARTEN, the name of the pasture slopes that descend westwards to the south end of the lake Aegeri in the Swiss canton of Zug, about 2m. by road from the Sattel station on the railway line from Schwyz to Zürich. It was at the foot of these slopes and on the shore of the lake that the small Swiss force defeated the large Austrian army, advancing from Zug on Schwyz, on Nov. 15, 1315, and so laid the foundations of Swiss liberty. For an account of the battle and its military significance *see* Swiss Wars. As the lake has shrunk, the exact site of the battle has been disputed.

The original accounts of the battle are collected in part iii. (1884) of the *Mitteilungen* of the Historical Society of Schwyz. *See* also the careful study in K. Bürkli's *Ein Denkmal am Morgarten; wo ist sein Platz?* (Zug, 1895).

MORGEN, a unit of measurement of land in Holland and the Dutch colonies, and hence still current in South Africa, equivalent to about 2 acres. It is also used in Prussia, Norway and Denmark, where it equals about two-thirds of an acre. The word is usually taken to be the same as the German and Dutch word for "morning," the area of a "morgen" being equal to that covered by a morning's ploughing.

MORGHEN, RAFFAELLO SANZIO (1758–1833), Italian engraver, was born at Naples on June 19, 1758. He studied first under his father, and then under the celebrated Volpato. He assisted this master in engraving the famous pictures of Raphael in the Vatican, and the print which represents the miracle of Bolsena is inscribed with his name. He married Volpato's daughter, and removed to Florence to engrave the masterpieces of the Florentine gallery. The grand duke commissioned him to engrave the "Last Supper" of Leonardo da Vinci. In 1812 Napoleon invited him to Paris and paid him the most flattering attentions. He died at Florence on April 8, 1833.

MORIAH, a place-name of ancient Palestine with two distinct connotations. (1) A land entirely unknown, on a mountain in which Abraham offered Isaac (Gen. xxii. 2). Traditionally, "the land of Moriah" is identified with the site of the Temple at Jerusalem, except by the Samaritans and a few western scholars (such as Dean Stanley) who accept their belief that the mountain was Gerizim. (2) The upper part of the hill of Ophel, the threshing floor of Araunah, upon which Solomon erected the Temple, was once called Mount Moriah (2 Chron. iii. 1). Whether this name be derived from the corruption in Genesis or not cannot be definitely decided; the testimony of Josephus, who often names the temple hill "Moriah," is of course not original.

MORIER, JAMES (1780–1849), English traveller and author, was born in 1780. Through the influence of his uncle, Admiral William Waldegrave, Baron Radstock, he entered the diplomatic service, and as secretary to Lord Elgin followed the grand vizier in the Egyptian campaign. From 1810 to 1816 he was the British representative at the court of Persia. His enduring fame rests on *The Adventures of Hajji Baba of Ispahan* (1824) and *The Adventures of Hajji Baba of Ispahan in England* (1828), one of the most entertaining books on the East ever written, and a most amusing satire on western civilization. *Hajji Baba* has been frequently reprinted. Morier died at Brighton on March 23, 1849. He also wrote books about his Eastern experiences.

MORIER, SIR ROBERT BURNETT DAVID (1826–1893), British diplomatist, was born at Paris on March 31, 1826. On leaving Balliol College, Oxford, where his life-long friendship with Jowett had begun, he obtained an appointment in the Education Department, but resigned in 1852, and in the following year became attaché at Vienna. In the succeeding years he was attached to almost every court in Germany. While secretary of legation at Darmstadt in 1866–71, he became a trusted adviser of the crown princess, and through her acquired an intimate friendship with the crown prince (afterwards the emperor Frederick III.). Bismarck, already jealous of British influence at court, honoured Morier with a hatred not lessened by the fact that Morier's knowledge of German politics was unrivalled outside Germany. On leaving Darmstadt, Morier became chargé d'affaires, first at Stuttgart and then at Munich, and in 1876 was

appointed minister at Lisbon. He was minister at Madrid from 1881 to 1884 when he became ambassador at St. Petersburg. Bismarck now took alarm at the lessening influence of Germany over Russia, and tried to procure Morier's downfall. The *Kölnische Zeitung* declared in Dec. 1888 that Morier had used his position at Darmstadt during the Franco-German War to betray the movements of the German troops to Marshal Bazaine. The authority for this charge was an alleged declaration made by Bazaine to the German military attaché at Madrid. Bazaine had died in September, but Morier had previously procured from him a written denial, which he now published in *The Times.* Morier was appointed Lord Dufferin's successor at Rome in 1891; but before he could take up office, he died at Montreux on Nov. 16, 1893.

See *Memoirs and the Letters of the Rt. Hon. Sir Robert Morier from 1826 to 1876* by his daughter, Mrs. Rosslyn Wemyss (2 vols., 1911) and I. Neumann's *Die Gesch. der deutschen Reichsgründung nach den Memoiren von Sir Robert Morier* (1919).

MÖRIKE, EDUARD FRIEDRICH (1804–1875), German poet, born at Ludwigsburg on Sept. 8, 1804, was lecturer in literature at the Katharinenstift in Stuttgart from 1851 to 1866. He died at Stuttgart on June 4, 1875. Mörike is the most lyrically gifted of all the poets belonging to the so-called Swabian school which gathered round Uhland. His works include *Gedichte* (1838; 22nd ed., 1905); *Idylle vom Bodensee, oder Fischer Martin und die Glockendiebe* (1846; 2nd ed., 1856); *Klassische Blumenlese* (1840) and several novels, among them the subjective and romantic *Maler Nolten* (1832; 6th ed., 1901).

See Mörike's *Gesammelte Schriften* (4 vols., 1878), and the *Volksausgabe* (4 vols., 1905). Selections from his literary remains were published by R. Krauss in *Eduard Mörike als Gelegenheitsdichter* (1895), and his correspondence with Hermann Kurz, Moritz von Schwind and Theodor Storm, by J. Bächtold (1885–91); an edition of Mörike's *Ausgewählte Briefe,* in 2 vols., appeared 1903–04. *See* H. Maync, *E. Mörike, sein Leben und Dichten* (1902; 4th rev. ed. 1927); K. Fischer, *Mörikes künstlerisches Schaffen und dichterische Schöpfungen* (1903).

MORIN, JEAN (latinized JOANNES MORINUS) (1591–1659), French theologian, was born in 1591 at Blois, of Protestant parents. He learned Latin and Greek at Rochelle, and continued his studies at Leiden, subsequently removing to Paris. His conversion to the Roman Church is ascribed to Cardinal du Perron. In 1618 he joined the congregation of the Oratory, and in due course took priest's orders. In 1625 he visited England in the train of Henrietta Maria; in 1640 he was at Rome, on the invitation of Cardinal Barberini, and was received with special favour by Pope Urban VIII. He was, however, soon recalled to Paris by Richelieu, and the rest of his life was spent in incessant literary labour. The *Histoire de la délivrance de l'église chrétienne par l'emp. Constantin* (1630), gave great offence at Rome, and a *Déclaration* (1654), directed against faults in the administration of the Oratory, was strictly suppressed. So, too, his great work on penance gave equal offence to the Jesuits and to Port-Royal, and even after his death, in 1659, the polemical vehemence of his *Exercitationes biblicae* long led Protestants to neglect his work in which he destroyed the current theory of the integrity of the Hebrew text of the Scriptures.

Morin's fame rests on his *editio princeps* of the Samaritan Pentateuch and Targum, in the Paris Polyglott, which gave the first impulse in Europe to the study of this dialect, which he acquired without a teacher (framing a grammar for himself) by the study of mss. then newly brought to Europe.

MORION, a light round-shaped head-piece or helmet (*q.v.*).

MORIORI. The Moriori, the almost extinct inhabitants of the Chatham islands, are a Polynesian people of culture allied to that of the Maori of the South Island. But having to contend with a more unfavourable environment, their arts and crafts were of a ruder kind. They had no cultivated foods, but lived on fern-root, eels, fish, *karaka* berries and birds. Albatrosses were obtained by perilous expeditions to the outlying rocks where they nested. The clothing of the Moriori was of sealskin and rudely woven flax. Their social organization was similar to that of the Maori but they were a peaceful people, quarrels being settled by a duel with a kind of single-stick. Hence they were easily conquered and enslaved by a warlike party of Maori in 1835.

MORISCOS (*i.e.,* "little Moors"), the name given to the Spanish Mohammedans who accepted baptism and their descendants. Many, if not most, of them were in reality of the same race as the Christians, and were descended from converts to Islam. By the terms of the capitulation of Granada in 1492 freedom of worship was secured to the Mohammedans. But at the end of 1499 Cardinal Jimenez insisted on adopting coercive measures. A rebellion ensued, and the Mohammedans were suppressed. Want of power, or other obstacles, delayed the final extinction of tolerated Mohammedanism in all parts of Spain, but by 1525 it was everywhere suppressed. As they were dependent on the protection of the landlords, the Mohammedans were docile tenants, and their competition weighed heavily on the Christians. The same quality of industry remained to the Moriscos, and excited the envy of their Christian fellow-countrymen. In 1568 the government of Philip II. issued an edict, which ordered them to renounce all their Moorish ways of life and to give up their children to be educated by Christian priests. The result was a rebellion in Granada, which was put down with great difficulty, the Moriscos being finally expelled from the city and scattered over other parts of Spain. The expulsion of the whole body of Moriscos from all Spain was decided on in 1608. The edict was published on Sept. 22 1609, and the expulsion was carried out with great cruelty. The number driven out has been variously estimated at 120,000 or at 3,000,000.

See H. C. Lea, *The Moriscos of Spain: Their Conversion and Expulsion* (1901).

MORITZ, KARL PHILIPP (1757–1793), German author, was born at Hameln on the Weser on Sept. 15, 1757, of humble parentage. He was apprenticed to a hat-maker, but later on studied philosophy at Erfurt and Wittenberg in 1777. While on a tour through Italy in 1786 he became acquainted with Goethe, who interested himself in him. On his return, he became professor of archaeology and aesthetics, at the Berlin academy. He died on June 26, 1793. Of Moritz's writings on aesthetic, archaeological and philosophical subjects, the little treatise *Über die bildende Nachahmung des Schönen* (1788; repr. 1888) and *Die Götterlehre* (1791; 10th ed., 1855, a reprint in Reclam's *Universalbibliothek,* 1878) are important; interesting, too, are the accounts of his travels, *Reisen eines Deutschen in England* (1788; repr. 1903; also trans. into Eng.) and *Reisen eines Deutschen in Italien* (3 vols., 1792–1793). But he is best known by his two novels, *Anton Reiser* (1785–1790; new ed. by L. Geiger, 1886) and *Andreas Hartknopf* (1786), which are mainly autobiographical, and give an admirable idea of the intellectual life of the *Sturm und Drang* period of German letters.

See K. F. Klischnig, *Erinnerungen aus den zehn letzten Lebensjahren meines Freundes Anton Reiser* (1794); Varnhagen von Ense, *Denkwürdigkeiten,* vol. iv. (1838); and M. Dessoir, *Karl Philipp Moritz als Aesthetiker* (1889).

MORLAIX, a town of western France, capital of an *arrondissement* in the department of Finistère, 37 m. E.N.E. of Brest on the railway to Rennes. Pop. (1926) 11,483. Coin finds suggest that Morlaix was probably occupied in the time of the Romans. The counts of Leon held the lordship in the 12th century, but the dukes of Brittany disputed possession with them, and in 1187 Henry II. of England, guardian of Arthur of Brittany, besieged and took the town. During the Hundred Years' War Morlaix was held by French and English in turn, and was pillaged by the latter in 1522. Mary Queen of Scots, on her way to be married to the dauphin, made solemn entry into Morlaix in 1548. The town having joined the League, the castle was taken by storm in the name of Henry IV. in 1594. Morlaix lies 5 m. from the English Channel in a narrow valley. Below the town the river Dossen widens into an estuary, the mouth of which is commanded by the Château du Taureau, built in 1542 for defence against the English. The railway from Paris to Brest crosses

the valley on a two-storeyed viaduct 200 ft. above the quays. Morlaix contains several wooden houses of the 15th, 16th and 17th centuries. These have large covered courts, with huge open fireplaces and carved wooden staircases, supported on pillars, leading from the court to the upper storeys.

The town of Morlaix has a sub-prefecture, besides a tribunal of commerce and a chamber of commerce. The industries include the manufacture of tobacco, tanning, brewing and the manufacture of casks, wooden shoes and candles; there is an active trade in grain, agricultural produce, oil-seeds, leather, wax, honey and in horses and other livestock. Fruit and vegetables are exported to Great Britain and the Channel islands. The port, consisting of an outer tidal harbour and an inner basin, admits vessels drawing 16 ft. at spring tides and 11 ft. at neap tides.

MORLAND, GEORGE (1763–1804), English painter of animals and rustic scenes, was born in London on June 26, 1763. His father and grandfather were both artists, and his mother is usually identified with a Maria Morland, who exhibited at the Academy in 1785 and 1786. Morland exhibited sketches at the Royal Academy in 1773 when he was only ten years old; he exhibited at the Free Society in 1775 and 1776, at the Society of Artists in 1777, and at the Royal Academy in 1778, 1779 and 1780. He studied for a short time at the Royal Academy, but from the age of 14 was apprenticed to his father, who was artist, engraver and picture-restorer. Before his apprenticeship came to an end Romney offered to take Morland into his studio for three years, with a salary of £300 a year, but the offer was rejected. As soon as Morland was free from his dull, respectable home, he began a career of reckless prodigality. In 1785 he was in France, and in 1786 he married Anne, the sister of William Ward, the engraver.

At this time Morland painted the six pictures known as the Laetitia series, engraved by J. R. Smith, and four other didactic works, "The Idle and the Industrious Mechanic" and "The Idle Laundress and the Industrious Cottager," engraved by Blake. When he moved from Pleasant Passage, Hampstead road, where he lived after his marriage, to Warren place, he began the extravagant course which ruined him. In 1799 he was sent to King's Bench prison, where he lived "within the rules," occupying a small furnished house in St. George's Fields with his wife and his brother Henry, but keeping his exact residence a secret. From this time onward he worked chiefly for his brother, who, like his friends, regarded him as a gold mine and exploited him shamelessly. Henry Morland found it advantageous to employ him at a daily fee of from two to ten guineas. In 1802 he was set free, but in 1803 had to place himself in the custody of the Marshalsea to avoid his creditors. Dissipation had already ruined his health. His left hand was paralyzed, apoplectic fits became frequent and his nerves were completely shattered. He now lived for long periods with his brother, to whom he always returned after a fierce quarrel had caused temporary absence. On Oct. 19, 1804, during one of these absences, he was arrested for a small debt and taken to a sponging-house. There he stayed, refusing all offers of help. While trying to make a drawing which could be sold in discharge of the debt he was seized with a fit. This led to an attack of brain fever of which he died on Oct. 29.

Morland's career is represented as one long record of imprisonments for debt, but his capacity for work was astounding, and when he was not painting he was usually recording impressions. According to one biographer, Dawe, he painted 492 pictures for his brother alone between 1796 and his death.

The finest of his pictures were executed between 1790 and 1794, and amongst them his "Inside of a Stable," in the National Gallery, may be reckoned as a masterpiece. His scenes in rustic and homely life show much instinctive feeling for nature. His colouring is mellow, rich in tone, and vibrant in quality, but, with all their charm, his works reveal often signs of the haste with which they were painted and the carelessness with which they were drawn. As a painter of English scenes he takes the very highest position. Many of his best works have been well rendered in mezzo-tint by J. R. Smith, W. Ward, his brother-in-law, P. Dawe, G. Keating, S. W. Reynolds and other engravers. He exhibited regularly at the Royal Academy from 1784 to 1804, but few of his Academy pictures can be identified owing to the inadequate description of them afforded by their titles. Both the originals and the mezzo-tint engravings still sell for high prices: the Laetitia series were sold for £5,600 in 1904 and "Dancing Dogs" fetched 4,000 guineas in 1905.

Four biographies of him appeared shortly after his death, written by W. Collins (1805), F. W. Blagdon (1806), J. Hassell (1806) and George Dawe (1807). Later biographies are those by Ralph Richardson (1895), J. T. Nettleship (1898), G. C. Williamson (1904 and 1907), Sir Walter Gilbey and E. D. Cumming (1907).

MORLEY, HENRY (1822–1894), British man of letters, was born in London on Sept. 15, 1822. He was sent to the Moravian school at Neuwied, whose system strongly influenced his subsequent theories of education. After an experiment in medical practice, which failed through the dishonesty of his partner, he set up a small school for young children at Liscard, near Liverpool. His principle was to abolish all punishment, to make his pupils regard their work as interesting instead of repellent, and to form their character by appealing exclusively to higher motives. The scheme proved a complete success. In 1851 he settled in London, on the invitation of Charles Dickens, as a regular contributor to *Household Words.* He was also on the staff of the *Examiner,* which he edited from 1861 to 1867. Meanwhile he wrote admirable monographs on *Palissy the Potter* (1852), *Jerome Cardan* (1854), *Cornelius Agrippa* (1856), *and Clément Marot* (1870). His dramatic criticisms were reprinted in 1866 under the title of *The Journal of a London Playgoer, 1851–1866.* In 1857 he was appointed evening lecturer in English literature at King's College, and in 1865 succeeded David Masson as professor of English literature at University college, London. He published in 1864 the first volume of a monumental history of English literature entitled *English Writers,* which he eventually carried in eleven volumes down to the death of Shakespeare. He was indefatigable as a popularizer of good literature. After editing a standard text of Addison's *Spectator,* he brought out a vast number of classics at low prices in Morley's Universal Library, Cassell's National Library and the Carisbrooke Library. In 1882 he became principal of University Hall, which was a place of residence for students of University college and the home of Manchester New college. Morley was an untiring advocate of a teaching university for London. In 1889 he resigned his offices and retired to Carisbrooke, Isle of Wight, intending to devote his leisure to the completion of his *English Writers.* But with his work only half achieved he died on May 14, 1894.

MORLEY [of Blackburn], **JOHN MORLEY,** Viscount (1838–1923), English statesman and author, was born at Blackburn on Dec. 24, 1838, the son of Jonathan Morley, surgeon. He matriculated at Lincoln college, Oxford, in 1856, and in 1859 came up to London to pursue a literary career. He became editor of the moribund *Literary Gazette,* which not all his ability could preserve from extinction. Gradually, however, he became known as a philosopher and a radical, and as one of the ablest and most incisive contributors to the literary and political press of the day. His sympathies as a thinker seem to have been at this time chiefly with positivism, and he acquired a reputation as an agnostic, which became confirmed in the popular mind when he somewhat aggressively spelt God in one of his essays with a small "g." From 1868 to 1870 he was editor of the daily *Morning Star.* In 1867 he succeeded G. H. Lewes in the editorship of the *Fortnightly Review,* which he conducted with brilliant success until 1883, when he was elected to parliament; he then assumed in exchange, but not for long, the editorship of *Macmillan's Magazine.* He had been connected with Messrs. Macmillan since the commencement under his editorship, in 1878, of the "English Men of Letters" series, in which nothing is better than the editor's own contribution, *Life of Edmund Burke,* an extension of his article in the 9th edition of this encyclopædia (1876). Since 1880 he had also been editor of the *Pall Mall Gazette,* which had been turned into a Liberal paper. (*See* Newspapers.)

In 1883 Morley, who had twice unsuccessfully attempted to enter parliament, was returned for Newcastle-upon-Tyne at a by-election. The prestige thus acquired led to his presiding over a

great Liberal congress at Leeds in the same year; and, although the platform never seemed his natural element, the literary finish of his style and the transparent honesty of his reasoning rapidly gained him a prominent position in the House of Commons. When, in February 1886, Gladstone returned to office as a home ruler, Morley, who had never before held any public appointment, filled one of the most important posts in the cabinet as secretary for Ireland. He had always expressed his sympathy with the Irish Nationalist movement. He had no opinions to recant, no pledges to explain away. He is credited with an especial influence over Gladstone in the matter of home rule, and in particular with having kept him steady in the Bill of 1886 to his original purpose of entirely separating the Irish from the British legislature, a provision which pressure from their own party afterwards compelled both of them to abandon. After the severe defeat of the Gladstonian party at the general election of 1886, Morley led a life divided between politics and letters until Gladstone's return to power in 1892, when he resumed his former office. There was a strong current of disapproval in his own constituency of his attitude to the Eight Hours' Labour Bill, which he regarded as an interference with personal liberty, and to a less degree of his anti-Imperialist views. The result was that at the election of 1895 he lost his seat, but soon found another in Scotland, for the Montrose Burghs. He had during the interval taken a leading part in parliament, but his tenure of the chief secretaryship of Ireland was hardly a success. The Irish gentry, of course, made things as difficult for him as possible, and the path of an avowed home ruler installed in office at Dublin Castle was beset with pitfalls. In the intestine disputes which agitated the Liberal party during Rosebery's administration, and afterwards, Morley sided with Sir William Harcourt, and was the recipient and practically co-signatory of his letter resigning the Liberal leadership in December 1898.

Morley's activities were now again turned to literature, the political views most characteristic of him, on the Boer war in particular, being practically swamped by the overwhelming predominance of unionism and imperialism. As a man of letters his work was practically concluded at this period, and may briefly be characterized. His position as a leading English writer had early been determined by his monographs on *Voltaire* (1872), *Rousseau* (1873), *Diderot and the Encyclopaedists* (1878), *Burke* (1879), and *Walpole* (1889). His *Life of Oliver Cromwell* (1900) revises Gardiner as Gardiner revised Carlyle. The *Life of Cobden* (1881) is an able defence of that statesman's views rather than a critical biography or a real picture of the period. He had the true admiration of the philosopher for the man of action, Walpole and Cromwell fascinated him for this reason, and Stafford perhaps more than they. At the same time his political experience gave him a wider view of the necessities of practical statesmanship than, for instance, Acton. Morley's contributions to political journalism and to literary, ethical and philosophical criticism were numerous and valuable. They show great individuality of character, and recall the personality of John Stuart Mill, with whose mode of thought he had many affinities. As in letters, so in politics. A philosophical radical of a somewhat mid-19th-century type, and highly suspicious of the later opportunistic reaction (in all its forms) against Cobdenite principles, he yet retained the respect of the majority whom it was his usual fate to find against him in English politics by the indomitable consistency of his principles and by sheer force of character and honesty of conviction and utterance.

After the death of Gladstone Morley was principally engaged upon his biography. Representing as it does so competent a writer's sifting of a mass of material, the *Life of Gladstone* (1903), was a masterly account of the career of the great Liberal statesman; traces of liberal bias were inevitable but are rarely manifest; and in spite of the *a priori* unlikelihood of a full appreciation of Gladstone's powerful religious interests from such a quarter, the whole treatment is characterized by sympathy and judgment. In 1902 he received the new Order of Merit.

When Campbell-Bannerman formed his cabinet at the end of 1905 Morley became secretary of state for India. In this position he was conspicuous in May 1907 and afterwards for his firmness in sanctioning extreme measures for dealing with the outbreak in India of alarming symptoms of sedition, in which he was bitterly attacked by some of the more extreme members of the Radical party. At the same time he showed his popular sympathies by appointing two distinguished native Indians to the council, and taking steps for a decentralization of the administrative government. When Campbell-Bannerman resigned in 1908 and Asquith became prime minister, Morley retained his post in the new cabinet; but was transferred to the upper house, with the title of Viscount Morley of Blackburn. His subsequent career at the India Office will always be associated with his extensive remodelling (1908–1909) of the system of government in India so as to introduce more fully the representative element. (*See* INDIA.) In his tenure of this office he showed again something of the philosopher's leaning to despotism. He admittedly kept his private conclusions out of his public actions, to a certain extent. The author of the essay *On Compromise*, the very Gospel of dissent, was in practice convinced that "the first duty of a government is to govern," and there was never a secretary of state who treated his viceroy more despotically. (*See* MINTO, EARL OF.) Similarly by communicating privately with the viceroy he tended to deprive the Council of State of information and influence on foreign policy. And though primarily responsible for the first great step towards Indian self-government, he disowned the Montagu-Chelmsford reforms as premature.

Lord Morley held the seals of the India Office till Nov. 1910. One of his last official acts had been to resist the appointment of Kitchener to the vice-royalty, pressed strongly upon ministers by King Edward just before his death. Morley remained in the cabinet as lord president of the council, and was one of the four counsellors of state to administer the kingdom during King George's visit to India in 1911–12.

In the critical period of domestic politics which began with the budget of 1909 he played a somewhat prominent part. He defended that budget in the great debate of November 1909 and, while admitting that the Lords had the legal right of rejection, said that to assert it was a "gambler's throw." Morley led the House of Lords during most of the session in which the Parliament bill, which he warmly supported, was passed; and it was he who read out to the House on the last night of debate that definite assurance from King George of his assent to a creation of peers which finally secured the exiguous but adequate majority of 17.

The entrance of Great Britain into the World War brought Morley's official career to an abrupt termination. He felt that his pacifist outlook was sufficiently well-known to make it unnecessary for him to give reasons for resigning; and he retired to Wimbledon, where he wrote his *Recollections* (2 vols. 1917). In 1921 his publishers brought out a complete edition of his works; and he was generally regarded, during his last years, as sharing with Mr. Hardy the position of *doyen* of English men of letters. He died at Wimbledon on Sept. 23, 1923.

See, in addition to the *Recollections*, Sardār 'Ali Khan, *Life of Lord Morley* (1923); J. H. Morgan, *John, Viscount Morley* (1924); F. W. Hirst, *Early Life and Letters of John Morley* (1927). Morley's *Memorandum on Resignation*, 1917, was posthumously published in 1928.

MORLEY, SAMUEL (1809–1886), English manufacturer and politician, was born on Oct. 15, 1809 at Homerton, the youngest son of a Nottingham hosier. In 1825 he entered his father's London warehouse, and when his father retired in 1840 became practical head of the London concern, and when his brothers retired in 1855 sole owner. In 1860 he was sole owner also of the Nottingham business, which grew rapidly, with huge mills at Nottingham and in Leicestershire and Derbyshire employing thousands of hands. In 1865 Morley was elected Liberal M.P. for Nottingham, and from 1868–85 sat for a Bristol division. He was one of the principal proprietors of the London *Daily News*. Morley was a deeply religious man, interested in the temperance movement, unstinting in charity, and a model employer. He died on Sept. 5, 1886.

See E. Hodder, *Life of Samuel Morley* (1887); F. M. Thomas, *I. and R. Morley: a Record of a Hundred Years* (1900).

MORLEY, THOMAS (1557–1603), English musical composer, was a pupil of William Byrd, but nothing is known as to his origin and very little as to the incidents of his career. He was admitted (July 5, 1588) Mus. Bac. at Oxford, and in 1596 entered the Chapel Royal, where he successively filled the offices of epistler and gospeller. On Sept. 11, 1598, Morley received a licence for twenty-one years to print ruled music-paper and songbooks in English, Latin, French or Italian. His rights under this grant were assigned to him by various publishers. On Oct. 7, 1602, his place in the Chapel Royal was filled up, and on Oct. 25, 1603, administration of his goods was granted to his widow. Morley was incontestably one of the greatest of the secular Elizabethan composers. His madrigals, canzonets and ballets are remarkable for their beauty and admirable workmanship, and his *Plaine and Easie Introductione to Practicall Musicke,* in spite of its frequent obscurity, is invaluable for the history of musical science in England.

His works are: (1) *Canzonets to Three Voices* (1593; 2nd ed., 1606; 3rd ed., 1631; Ger. trans.: Cassel, 1612, and Rostock, 1624); (2) *Madrigals to Four Voices* (1594; 2nd ed., 1600); (3) *First Book of Ballets to Five Voices* (1595; an Ital. ed. appeared in London in the same year; 2nd ed., 1600; Ger. ed., Nuremberg, 1609); (4) *First Book of Canzonets to Two Voices* (1595; 2nd ed., 1619); (5) *Canzonets or Short Little Songs to Four Voices, selected out of Italian Authors* (1597); (6) *Canzonets to Five and Six Voices* (1597); (7) *A Plaine and Easie Introduction to Practicall Musicke* (1597; 2nd ed., 1608; 3rd ed., 1771); (8) *Madrigals to Five Voices, selected out of Italian Authors* (1598); (9) *The First Book of Consort Lessons, made by divers authors, &c.* (1599; 2nd ed., 1611); (10) *The First Book of Airs to Sing and Play to the Lute with the Base Viol* (1600); (11) *The Triumphs of Oriana to Five and Six Voices, composed by divers several authors* (1601). Besides the above, services, anthems, motets and virginal pieces by Morley are to be found in various collections, both printed and manuscript.

MORLEY, a municipal borough in the West Riding of Yorkshire, England, 4 m. S.S.W. of Leeds, on the L.M.S. and L.N.E. railways. Pop. (1931), 23,397. The town is situated on a spur of the Pennines, at an altitude of about 450 feet. In the neighbourhood are the ruins of Hawley Hall, dating from 1590. Here, during the Civil War, the parliamentary army sustained a heavy siege from the Royalists. The chief industries are connected with woollen cloth, but coal mining and stone quarrying are carried on, and machinery is manufactured. The borough, which was incorporated in 1885, has a mayor, 7 aldermen, and 21 councillors.

MORMAOR or MORMAER, a title used to designate the rulers of the seven provinces into which Celtic Scotland, *i.e.*, the part of the country north of the Forth and the Clyde, was divided (Gael. *mor*, great, and *maor*, steward or bailiff). These seven mormaorships, or original "earldoms" of Scotland, as they were afterwards called, were: Angus, Athole with Gowry, Caithness with Sutherland, Fife, Mar with Buchan, Moray with Ross, and Stratherne with Menteith.

MORMONISM does not claim to be a new religion, but regards itself as a new dispensation of the one and only Gospel of the Lord Jesus Christ; God's plan of "Eternal Life, which God, that cannot lie, promised before the world began." (Titus 1:2.) But while there is but one gospel, there have been many dispensations of it, by reason of men from time to time "falling away" from the order of things God has revealed to them. Ultimately, however, according to Mormon beliefs, and their interpretations of the Jewish and Christian documents, there is to be a final or last dispensation of this one and only "everlasting Gospel," known as the "dispensation of the fullness of times," in which all things pertaining to the redemption of the earth and the salvation of man will be gathered together in one, both in heaven and in earth. (Eph. 1:9–10.) The appearing of God the Father and his Son Jesus Christ to Joseph Smith, the bringing forth of the Book of Mormon, the alleged American volume of scripture, and the organization of the Church of Jesus Christ of Latter-Day Saints, was the beginning of this promised dispensation of the fullness of times.

Authoritative Sources of Doctrine.—The Church of Jesus Christ of Latter-Day Saints recognizes two sources of doctrine; (1) the written word of God—the scriptures; and (2) direct revelation from God. The books accepted as scripture are: (1) the Bible, the Old and the New Testament, as far as they are correctly translated from the original documents; (2) The Book of Mormon, an alleged ancient American record, said to have been translated by Joseph Smith, "by the gift and power of God"; (3) The Doctrine and Covenants, a collection of revelations given in the present day, chiefly through Joseph Smith; (4) The Pearl of Great Price, a collection of fragments from writings of Moses and Abraham, not found in the Bible, but purported to have been revealed to Joseph Smith; also some historical and doctrinal writings of Joseph Smith's. These four books have been officially accepted as scripture by vote of the Church. All other writings and discourses are of secondary character and of value in proportion to their strict conformity to the above named books of scripture.

The Church believes in present day and continuous revelation: by direct word of mouth and visible presence of God; by voice communication without visible presence; by visitation of angels and deliverance of messages; also by impressions upon the mind of man by the Spirit of God. Revelation in any of these manners is the supreme source of knowledge, and the final arbiter of doctrine for the Church, even superior to the written word.

It is the doctrine of the Church that its members have the right to divine guidance through revelation for their individual lives; as also all officers of the Church in their respective callings and stations, but not for the guidance of the Church or the domination of others. There is but one man on the earth at a time, when the Church is established, who may receive revelation for the guidance of the Church, and he is the President of the Church, God's Prophet, Seer and Revelator and mouth-piece. His official word, when speaking in the name of the Lord, the Church is to receive as from God's own mouth. No revelation is of binding force as law upon the Church, however, until officially accepted by vote of the Church in general conference assembled.

Of Existences.—Mormon theology and philosophy take note of existences, of time, space, matter, the extent and nature of the universe. Duration is without beginning or end; space is limitless; matter, in its elemental status, eternal; and while subject to infinite mutations may neither be created nor annihilated. Mind—identical with intelligence—is equally eternal (Doc. and Cov, Sec. 93). Mind is that which directs action, matter that which is acted upon (Book of Mormon, II. Nephi, Ch. 2). From this action of mind or spirit upon matter, proceed all changes and accomplishments brought to pass in an eternal universe, where eternal cause is ceaselessly active under a universal reign of law. "There are many kingdoms (meaning worlds and world systems) for there is no space where there is no kingdom; and there is no kingdom in which there is no space, either a greater or a lesser kingdom. And to every kingdom is given a law; and to every law there are certain bounds also and conditions." These "kingdoms" or worlds and world systems, are inhabited by intelligences in varied states of development. Some are spirits who have passed through a mortal life and are awaiting resurrections; others are unbodied spirits, awaiting opportunity for birth into mortal life, that they may be put in the way of eternal progression. Also in some of these many kingdoms is an order of translated beings, men who have been brought into mortal life and then translated from that life—*i.e.*, death suspended as in the case of Enoch and his people, and Elijah (Gen. 5:21–24; Heb. 11:5; Pearl of Great Price, Book of Moses 7:67–69). Others have passed through mortal life to a resurrection which has brought them into immortal life where spirit and element are inseparably connected.

Of God.—In its doctrine of God, "Mormonism" is Christ-Theistic. It accepts Jesus Christ as the incarnation of Deity. He is God manifested in the flesh (I Tim. 3:16); a complete revelation of Deity in personality and in form; in intellectual and spiritual powers, having all the attributes of the Father, and possessing all power in heaven and in earth. (Heb. 1:1–3, Matt. 28:18.) There is but one God-nature, or essence, but many may be partakers of that one nature (II Peter 1:4); may be, in fact, incarnations of the God nature. "I and my Father are one,"

said Jesus (St. John 19:30; also St. John 14:17). The Trinity of Father, Son and Holy Ghost is accepted as illustrating this principle of one divine nature and a plurality of persons participating therein.

Proceeding from the presence of these divine personages is a "spirit" which "fills the immensity of space." "The light which is in all things, which giveth life to all things, which is the law by which all things are governed, even the power of God." (Doc. and Cov., Sec. 88:6–7.) This "the True Light, which lighteth every man that cometh into the world" (St. John 1:9); also is called the "Light which is the life of men" (St. John 1:4; *id.* 8:13). This Spirit is God immanent in the world (Doc. and Cov., 88:7–13); is everywhere consciousness, all seeing, all knowing; is an all-pervading and active Will; is possessed of all the qualities and attributes of God, save only form; and is in all who attain unto like perfect participation and fullness of the divine nature.

Of Man.—It is the declared purpose of God to bring to pass the immortality and eternal life of man. Essential to this is the inseparable union of spirit and element, the spirit and its bodily garment, constituting the perfect soul. (Doc. and Cov., sec. 88:15–16; *id.*, sec. 93.) Hence man's earth-life and his experience in the midst of broken harmonies; his death and his resurrection to immortality; all of which is necessary to his progress, that he may acquire the knowledge and have the wisdom which such experiences alone can teach. Man finds himself, and proves himself worthy of that eternal weight of glory, which it is God's purpose to grant to him; or by his failure to react to God's intent, he learns that he must abide in lesser degrees of glory on planes of existence in keeping with his limited capacity, or his unwillingness to make progress. In the Father's house are many mansions, of infinite degrees of glory, of which sun, moon and stars in all their infinitude of brightness are spoken of as being typical (I Cor. 15; Doc. and Cov., sec. 76).

The Gospel.—The means of attaining unto all that God has designed for man in his earth life are acceptance of and obedience to the gospel, of which Jesus Christ is the centre and circumference. He is the Redeemer and Savior of men, the resurrection and the life. By Him is brought to pass the forgiveness of sin, the resurrection to physical immortality, and the spirit birth into union with God.

Organization and Government.—The Mormon Church organization and government arise out of the priesthood. Priesthood is regarded as power delegated from God to man by which man is authorized to act in the name or the authority of God. The Aaronic priesthood has to do mainly with temporal affairs, the collection of tithes, the distribution of charities, the general care of its properties and the administration of the outward ordinances of the gospel, water baptism and the administration of the Lord's supper. The officers of this priesthood are bishops, priests, teachers and deacons. There is a general presidency over this priesthood known as the presiding bishopric of the Church, consisting of three high priests of the Melchizedek order, one of whom is the bishop, the other two counsellors. This bishopric is designated by the first presidency, ordained by them, and accepted and sustained by the vote of the Church. The Melchizedek priesthood has mainly to do with spiritual affairs, the proclamation of the truth to the world, and bearing witness of it, and exercising in the higher phases of Church activities administrative, legislative and judicial functions, even including supervision of temporal affairs. The officers of this priesthood are apostles, prophets, seers, revelators, patriarchs, high priests, seventies and elders. The two great duties of the Church are to make proclamation of her truth, and perfect the lives of those who receive it.

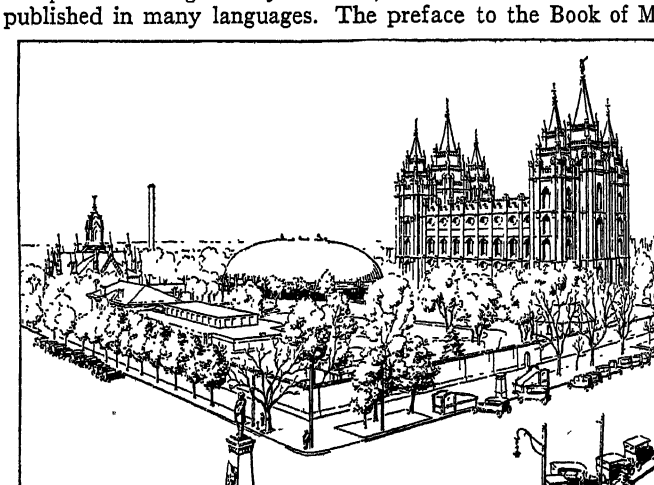
Territorially the Church holds a world-wide jurisdiction. It is the church universal—catholic in the widest sense. In America where the Church is intensively organized, a central place is recognized as Zion, located in Jackson County, Mo. Here a holy city is yet to be built by the Church, a New Jerusalem, into which will be gathered those of all nations. This will be the centre of administrative activities of the church universal, and the site of the chief temples. Other cities and settlements grouped conveniently for local administration purposes, outside of the central place, are to be, and now are, called "stakes of Zion."

To supplement the work of the priesthood there are The National Womans' Relief Society; the Sunday Schools; the Young Ladies' Mutual Improvement Associations; Primary Association, promoting mid-week child culture; and Religion Classes providing training side by side with secular education. The Church maintains a school system comprising high schools, seminaries and college grades, where, respectively, Mormon theology is made part of the Church school curriculum. (R. Sm.)

MORMONS or **LATTER-DAY SAINTS,** a religious society founded by Joseph Smith (*q.v.*) and associates at Fayette, Seneca County, New York, April 6, 1830. It was organized conformably to the laws of the State of New York, which required no fewer than six persons to constitute a religious society. Joseph Smith's associates were Oliver Cowdery, Hyrum Smith, Peter Whitmer, Jr., Samuel H. Smith and David Whitmer. In addition to these, a few others became members of the Church at the time of its organization.

Smith, when a boy between 14 and 15 years of age, claimed to have had, in answer to prayer, a vision in which two heavenly personages appeared to him and proclaimed the opening of a new Gospel dispensation. These personages, he said, were God the Father and his son, Jesus Christ. Afterwards, according to Joseph's account, a heavenly messenger appeared to him, giving his name as Moroni, and revealing the existence of a record engraved upon gold plates and hidden in a hill between Palmyra and Manchester, N. Y., not far from the Smith home; a record containing the fulness of Christ's Gospel, as made known by the risen Redeemer to the ancient inhabitants of America. Four years later, or on Sept. 22, 1827, the plates were delivered into Joseph's hands, and with them instruments called "interpreters" (Urim and Thummim), by which he translated the cryptic characters found upon the plates, and gave to the world the Book of Mormon—so called because its author and compiler was a prophet named Mormon, father to Moroni, who as a mortal had concealed the record in the hill.

The Book of Mormon was first published at Palmyra, N.Y., early in 1830, in an edition of five thousand copies. Since then it has passed through many editions, and has been translated and published in many languages. The preface to the Book of Mormon prints the testimony of three witnesses that they beheld the plates and the inscriptions from which the translation was made. Eight additional witnesses testified to the same. Following the publication of the book, came the organization of the Church of Jesus Christ of Latter-Day Saints, commonly called the Mormon Church, and its members Mormons, because of the *Book of Mormon,* believed by them to be of divine authenticity, and of equal authority with the Jewish Scriptures. At the organization of the Church, Smith and Oliver Cowdery were sustained respectively as its first and second Elders, and the former as Prophet, Seer and Revelator.



BY COURTESY OF THE CHICAGO BURLINGTON & QUINCY RAILROAD CO.

THE MORMON TABERNACLE AND TEMPLE AT SALT LAKE CITY

Mormonism drew its first proselytes from the rural districts of New England. In the autumn of 1830 it sent missionaries to the Indians living upon reservations in New York State and in newer States. These missionaries—Oliver Cowdery, Peter Whitmer, Jr., Parley P. Pratt and Ziba Peterson—proceeded westward and in Ohio converted a number of white people, including Sidney Rigdon and others who became prominent in the Latter-day Church. They continued onward to Western Missouri, which was then the frontier of the nation.

Ohio, the First "Stake of Zion."—About the same time, the infant Church, partly because of the opposition it encountered in New York, but mainly to be nearer the field of its future operations, moved to Kirtland, Ohio, where the first "Stake of Zion" was established, the first temple built, and the priesthood more thoroughly organized. A first presidency was created, Joseph Smith and two others being the incumbents. Twelve Apostles were chosen, with quorums of seventy to assist them. High priests, patriarchs, bishops and stake presidents were also among the offices instituted. The Church membership at that time was between 3,000 and 4,000.

In the summer of 1831 a Mormon colony settled in Jackson county, Mo., upon lands purchased from the Federal government, and consecrated by the Prophet as a site for the New Jerusalem. Most of these Mormons were from the North and East and were abolitionist in their tendencies, a very serious charge at that time when Missouri was a slaveholding State. Moreover they were poor and brought little property, yet they looked forward to their future possession of the country thereabouts as "The Land of Zion." This together with the religious and social differences, aroused the bitter opposition of the older settlers who, having no recourse to law, proceeded by violence and terrorizing to force the removal of the entire colony in the autumn of 1833 to Clay, Caldwell and Daviess counties in the same State.

The Mormons Leave Ohio.—Mormonism thrived despite this opposition, missions in Canada as well as in the States contributing many converts. The failure of the Kirtland Bank, an unchartered institution, in 1837, however, nearly wrecked the Church. Doubts of its soundness were present almost from the first. When Rigdon and Smith, respectively secretary and treasurer, were charged with violating the State law against unchartered banks, they appealed on the ground that it was not a bank but an association. The institution however suspended payment and closed its doors in November, 1837, as did many other banks throughout the country at this particular time. The failure created a bitter feeling against the Prophet on the part of many of his followers and a number of leading Elders fell away. Those who remained Smith's followers soon removed to Missouri, whither Smith and Rigdon had already gone, settling chiefly in Caldwell county where the Jackson county refugees had previously settled and where there were few inhabitants other than of Mormon faith. There they founded the City of Far West (now Kerr). They also projected a temple and laid out other towns.

Mormon missionary work in England helped to save the Church at this critical stage. Heber C. Kimball and Orson Hyde, two of the twelve Apostles, together with other elders, in 1837 began preaching in Lancashire and neighbouring parts of England and after about eight months had baptized nearly 2,000 persons. This was but the first of many missions in European countries, which countries were to furnish from their peasant classes a large proportion of the converts to Mormonism.

The Missouri Exodus.—Movements by Mormon settlers beyond Clay county into surrounding counties again led to clashes with the Missourians, who were now thoroughly aroused against the Mormons who were coming in such numbers as to seem to the gentiles a menace to the State. An election riot in Gallatin, where an attempt was made to prevent the Mormons from voting, was the spark that kindled a general conflagration. Armed bands of both parties were soon abroad in the country shedding blood and instituting a reign of lawlessness. Numbers were killed on both sides. Finally the governor ordered out the State militia against the Mormons. Their town of Far West was surrounded and their leaders captured. On their way to trial the leaders escaped and made their way to Illinois. The action of the State in support of the local Missourians gave the latter courage for further terrorization acts against the Mormons until they were forced to move.

The Illinois Period.—The mid-winter exodus of the Mormons from Missouri (1838–39) led to the founding of the city of Nauvoo on the east bank of the Mississippi, in Hancock county, Ill. In Missouri the Saints had numbered twelve to fifteen thousand; in Illinois this figure increased to about twenty thousand, most of them citizens of Nauvoo. There the Prophet resided and continued to direct the spiritual and temporal activities of the Church.

Under his direction Brigham Young, President of the Twelve Apostles, was sent with a majority of that council to England, to enlarge the work already begun there. The missionaries penetrating to all parts of the United Kingdom, converted 5,000 people, founded a periodical known as the *Millennial Star*, published a British edition of the *Book of Mormon*, printed and distributed thousands of tracts, and established a permanent shipping agency to carry forward the work of "gathering Israel to the Land of Zion." The first company migrating from Europe under these auspices, was a small group of 41, which sailed from Liverpool in June 1840, for Nauvoo via New York. Subsequently Mormon immigration from Europe passed up the Mississippi. The first half of the decade of the '40s witnessed the rapid growth of the Mormon community in Illinois and in Iowa. At Nauvoo a temple was built, a university projected, the city chartered and extended, and the Nauvoo Legion organized, under Legislative sanction, as a part of the State militia.

Difficulties and Dissension.—The Mormons had enemies in Illinois, however, and trouble was brewing. The Mormons at the time held the balance of political power in the State and were courted by both Whigs and Democrats. The Whigs had granted the Nauvoo charter, but their friendship was lost when Smith supported the Democrats in the gubernatorial campaign of 1842. Advising his people on other occasions to vote for the Whigs alienated the Democrats in turn. Political opposition was intensified when Smith in 1844 announced himself as a candidate for President of the United States. Meanwhile serious dissension occurred within the Church. Though not officially announced until 1852 it was in 1843 that Smith claimed to have received the revelation proclaiming the doctrine of plural marriages, which the Prophet acted upon by soon taking additional wives. The doctrine was also made known to some of the Elders who did likewise, though at first in secret. This practice led to the secession of William and Wilson Law, with others, from the church. They set up a paper called the *Nauvoo Expositor*. Smith as mayor of the city condemned the *Expositor* as a public nuisance and ordered its printing press and type to be destroyed. The order was carried out by the city marshal and police. The revelations of the *Expositor* and Smith's act in suppressing it aroused the entire country about Nauvoo to mob fury. Inflammatory speeches and exaggerated rumours of Mormon practices added fuel and gathered crowds. Smith proclaimed martial law in Nauvoo and allowed no one to enter the city. Governor Ford pacified the mob in Carthage by promising the Prophet should be made to answer the charges against him and at the same time he sent Smith notice to appear at Carthage. Smith hesitated to comply with the order, and even considered flight to the Rocky mountains, but was persuaded to surrender to the law. With his brother Hyrum and several other leaders he proceeded to Carthage, and, pending the trial, was placed with the others in the visitors' room of the Carthage jail, Governor Ford pledging the honour of the State for his protection. This pledge was violated by a mob of about 200 men who, with blackened faces, on the afternoon of June 27, assaulted the jail, and with the connivance of the guards shot to death Joseph and Hyrum Smith, and all but fatally wounded John Taylor; Willard Richards, their fellow prisoner, escaping unhurt.

When this crime was committed most of the Apostles were absent from Nauvoo. Upon hearing the tidings, they at once returned, and in August of that year (1844) succeeded to the leadership of the Church. Sidney Rigdon claimed the succession, by

virtue of having been Joseph Smith's counsellor in the first Presidency, the highest authority in the Church; the Twelve Apostles ranking next. But the Prophet's death had dissolved the First Presidency. Moreover, he had said: "Where I am not, there is no First Presidency over the Twelve." This ruling, overwhelmingly sustained by the people, disposed of Rigdon's claim and settled the question as to who should preside over the Church. A number of others parted company with the main body at that time, and founded the Reorganized Church of Jesus Christ of the Latter-Day Saints (*see* p. 811). The majority, however, followed Brigham Young and his fellow Apostles.

From Illinois to Utah.—Less than two years later came the enforced wintry exodus of the saints from Illinois, the first companies crossing the frozen Mississippi on the ice. Dragging their heavily loaded wagons across snow-covered, rain-soaked Iowa, tarrying on the way only long enough to found temporary settlements and sow crops to be reaped by those who followed them, the vanguard, in June 1846, reached the Missouri River, and by permission encamped temporarily on the Pottawatomie Indian lands. They were now on the nation's frontier.

It devolved upon Brigham Young (*q.v.*) to lead the migrating Mormons to their new home in the wilderness. During the troubles in Missouri he had given proof of his ability as an organizer and leader. His mission to Britain furnished additional evidence. He was the man of all men for the responsibility now resting upon him. At the head of a picked company numbering 143 men, three women and two children, Brigham Young, in April 1847, started to cross the great plains between the Missouri river and the Rocky mountains. (*See* UTAH: *History.*) In covered wagons, drawn by mules and oxen, they carried ploughs, implements, seed grain and a year's supply of provisions. Passing through the Indian country, over wide prairies and rugged mountains, these pioneers, on July 24th, entered the valley of the Great Salt lake, then uninhabited except by red men, and included in a region belonging to Mexico. At the close of the Mexican War the land was ceded to the United States.

Other companies of Mormon emigrants followed and, as soon as practicable, the settlers took steps to organize a civil government. In March 1849 they set up the Provisional State of Deseret, and petitioned Congress for admission into the Union. The prayer for Statehood failed, but the Territory of Utah was organized September 1850. Brigham Young was appointed Governor by President Fillmore, and at the expiration of a four year term, was reappointed by President Pierce.

Frontier Hardships.—Many hardships attended the colonization of the barren region in which these people made their home. Not only drouth, but crop-devouring crickets and grasshoppers, as well as blood-thirsty Indians, had to be dealt with and overcome. "It is better to feed the Indians than to fight them," said Brigham Young, and his wise policy prevailed, the warlike red men finally becoming friendly and peaceable. Drouth was conquered by irrigation, the Mormons being the pioneers in that art.

Political Relations with Federal Government.—There were also political difficulties between the Mormons and the U.S. officials sent to govern them and administer the law. Some of President Pierce's appointments were unfortunate in consideration of the delicate task which they faced, and the Mormons were justly aroused to anger by their deeds. On the other hand there was the evident determination of the Church to maintain its authority over civil affairs. Official after official returned to Washington, maintaining that his office was untenable, some of them reporting actual violence against them. It was rumoured that a crowd broke into the office of Judge George P. Stiles and seized the Federal court records along with the Judge's personal books and papers. The former were placed in a church safe, but the latter were burned. Stiles believed the court records were included in the bonfire and reported their destruction to Washington. Outrages against non-Mormons were continually reported and in the summer of 1857 occurred the famous Mountain Meadows massacre in which 120 men, women and children were killed by the Mormons and Indians. The Church has always disclaimed responsibility for this incident, but it, nevertheless, inflamed the people throughout the United States. President Buchanan soon after his inauguration decided to appoint a non-Mormon governor, and to back up his acts and those of other Federal officials with force if necessary, in order to restore U.S. authority. Alfred Cumming was appointed governor and Col. Albert Sidney Johnson was ordered to the territory with 1,500 troops in the autumn of 1857. He was shut out from Salt Lake Valley and compelled to winter east of the Wasatch mountains, the way being blocked by winter snows and the Territorial Militia acting under orders from Brigham Young. When spring came Gov. Cumming entered Salt Lake city and was received with every demonstration of good will. His reports were favourable to the Mormons and peace commissions sent by Buchanan were able to strike a compromise with the Mormon officials.

Brigham Young's Leadership.—The history of the Mormon Church during the thirty years that Brigham Young presided over it, is to a large extent the history of the settling up and development of the Inter-Mountain West during the same period of time. He and his people—many thousands of them emigrants from the Old World—spread their colonizing activities over Utah (*see* UTAH: *History*) and parts of Idaho (*q.v.*), Nevada (*q v.*), Colorado, Arizona and New Mexico. Young built temples, tabernacles, theatres, founded schools, and was at the head and front of every great mercantile, industrial, or educational movement in his vicinity. He also perpetuated the missionary system of the Church and extended it to most of the countries of the globe. After his death in 1877, he was succeeded by John Taylor, the senior Apostle in the Council of the Twelve.

Struggle over Polygamy.—President Taylor's administration was notable for the prosecution of plural marriage, commonly called polygamy, under the laws of Congress enacted against it. This form of marriage as practised by Joseph Smith and others in Illinois, had been perpetuated by the founders of Utah. Only a small percentage of the people ever engaged in it. As early as 1862, Congress had legislated against the institution, but the law proved inoperative, and was supplemented twenty years later by the Edmunds Law, still later by the Edmunds-Tucker Law. Under these statutes a vigorous crusade was carried on in Utah, Idaho and Arizona, wherever polygamists were found.

During the so-called "crusade" men and women were fined and imprisoned, certain Mormon leaders were driven into exile, and a great deal of suffering was inflicted before they could be induced to yield the point and "come within the law"—a law deemed by them unconstitutional, infringing upon religious liberty. In 1890, after the United States Supreme Court had affirmed the constitutionality of the anti-polygamy laws, President Wilford Woodruff, who was then at the head of the church, issued a Manifesto, announcing his intention to submit to the laws of the land in relation to plural marriage, and advising all other Latter-Day Saints to do the same. The General Conference in October sustained the Manifesto and thus withdrew sanction from the further solemnization of plural marriages in the Mormon Church.

A change of feeling ensued. Mormons and non-Mormons, in Utah and elsewhere, became more friendly with each other. Presidents Benjamin Harrison and Grover Cleveland, in successive proclamations, pardoned all polygamists, on condition of future obedience, the escheated Church property was returned, and in Jan. 1896, the Territory of Utah was admitted into the Union.

Later History and Status.—Since that time the Mormon Church has had three Presidents, all former members of the Council of the Twelve. Under President Lorenzo Snow, a natural financier, it was relieved of a heavy burden of debt, resulting partly from escheatment proceedings against Church property under the Edmunds-Tucker Law. Then came President Joseph F. Smith, son of the martyred Patriarch Hyrum Smith, and lastly President Heber J. Grant, the first Utah-born President.

The membership of the Mormon church was reported in 1924 as 535,659, an increase of about 200,000 since 1900. It was estimated that of all church members about 90% in Utah, 53% in Idaho, 24% in Nevada, 21% in Wyoming and 11% in Arizona were Mormons, these being the chief states in which the Church has gained a hold. Missionary work among the Mormons has al-

ways been and continues to be decidedly active. In 1924 the number of missionaries maintained in the United States was 1,092 and the number maintained in foreign lands was 779.

Bibliography.—No impartial and critical history of the Mormons yet exists. The *New York Public Library Bulletin,* Mar. 1909, contains a list of the Berrian collection at that library, which forms the most complete bibliography to be found. A typical Mormon textbook for school use is J. F. Smith (church historian), *Essentials in Church History* (1922). A larger work published by the church is *History of the Church of Jesus Christ of Latter-Day Saints* (1902–12). *See* also J. Q. Adams, *The Birth of Mormonism* (1916); W. E. La Rue, *The Foundations of Mormonism* (1919); Lucy Smith (mother of the Prophet), *Biographical Sketches of Joseph Smith* (1858); I. W. Riley, *The Founder of Mormonism* (1902); *William Clayton's Journal* (1921); H. H. Bancroft, *History of Utah* (1889); O. F. Whitney, *History of Utah* (1892–98); R. M. Werner, *Brigham Young* (1925); F. J. Cannon, *Under the Prophet in Utah* (1911); W. A. Linn, *The Story of the Mormons* (1902); J. H. McClintock, *Mormon Settlement in Arizona* (1921); E. E. Reorganized Church of Jesus Christ of Latter Day Saints.—This church claims to be the legal successor of the Church of Jesus Christ of Latter Day Saints founded by Joseph Smith. After Smith's death in 1844 a portion of the church rejected the leadership of Brigham Young. A reorganization was partially effected in 1852, and in 1860 Joseph Smith, son of the founder of the church, became its president, continuing till his death in 1914. He was succeeded by his son Frederick Madison Smith, who occupied that position in 1929.

The church rejects polygamy and certain other teachings introduced by Brigham Young and his associates, and adheres to the teachings of the original church as promulgated by its founder. It believes in God the Father, Christ his Son, and in the Holy Ghost, and holds that divine revelation, prophecy, healing, tongues and other spiritual gifts promised in the New Testament are to be enjoyed by the people of God today. It teaches faith, repentance, baptism, the laying on of hands, resurrection of the dead, and eternal judgment. It believes in a literal gathering to Zion, which by revelation is located in Missouri. In organization the church has a first presidency, twelve apostles, seventies, patriarchs or evangelists, bishops, elders, priests, teachers and deacons. It numbers (1929) more than 100,000 members with headquarters in Independence, Missouri.

MORMYR (*Mormyridae*), the name of a family of fishes restricted to the fresh-waters of Africa, soft rayed fishes with abdominal pelvic fins, a small mouth with few teeth, small eyes, restricted gill-openings and small scales. The brain is very large, with a great convoluted cerebellum, and enlargements in other regions that suggest that these fishes have the senses of taste and hearing particularly well developed. (V. Franz, *Zool. Jahrb. Anat. Abth.,* 1911.) A loosely attached bony plate on each side of the head covers a vesicle which communicates with the internal ear; paired electric organs are present in the tail. About 120 species are known, strange-looking fishes, exhibiting great diversity, some having the mouth at the end of a long snout which resembles the trunk of an elephant. Most feed on small prey, or on weeds or organic débris. The Nile species are represented in ancient Egyptian mural paintings and hieroglyphics.

MORNAY, PHILIPPE DE (1549–1623), seigneur du Plessis-Marly, usually known as Du-Plessis-Mornay or Mornay Du Plessis, French Protestant, was born at Buhy in Normandy on Nov. 5, 1549. His mother had leanings toward Protestantism, and, on his father's death in 1559, the family formally adopted the reformed faith. Mornay studied law and jurisprudence at Heidelberg in 1565 and the following year Hebrew and German at Padua. His career as Huguenot apologist began in 1571 with the work *Dissertation sur l'église visible,* and as diplomatist in 1572 when he undertook a confidential mission for Admiral de Coligny to William the Silent, prince of Orange. He escaped the St. Bartholomew massacre by the aid of a Catholic friend, and took refuge in England. Returning to France in 1573, he fought under Henry of Navarre. He was taken prisoner on Oct. 10, 1575, but not being recognized was ransomed for a small sum. Shortly afterwards he married Charlotte Arbaleste at Sedan. Mornay was gradually recognized as the right-hand man of the king of Navarre, whom he represented in England from 1577 to 1578 and again in 1580, and in the Low Countries 1581–82.

After the death of the prince of Condé in 1588 Mornay's influence became so great that he was popularly styled the Huguenot pope. He was present at the siege of Dieppe, fought at Ivry, and was at the siege of Rouen in 1591–92, until sent on a mission to the court of Queen Elizabeth. He was bitterly disappointed by Henry IV.'s abjuration of Protestantism in 1593, and thenceforth gradually withdrew from the court and devoted himself to writing. He founded in 1593 the Protestant academy or university at Saumur, which had a distinguished history until its suppression by Louis XIV. in 1683. In 1598 he published a work on which he had long been engaged, entitled *De l'institution, usage et doctrine du saint sacrement de l'eucharistie en l'église ancienne,* containing about 5,000 citations from the scriptures, fathers and schoolmen. Du Perron, bishop of Evreux, afterwards cardinal and archbishop of Sens, accused him of misquotation, and a public disputation was held at Fontainebleau on May 4, 1600. Decision was awarded to Du Perron. Mornay was deprived of the governorship of Saumur at the time of the Huguenot insurrection in 1621, and died in retirement on Nov. 11, 1623.

His principal works, in addition to *De l'institution, usage et doctrine du saint sacrement de l'eucharistie en l'église ancienne* (La Rochelle, 1598), mentioned above, are *Excellent discours de la vie et de la mort* (London, 1577), a bridal present to Charlotte Arbaleste; *Traité de l'église où l'on traite des principales questions qui ont été mues sur ce point en nostre temps* (London, 1578); *Traité de la verité de la religion chrétienne contre les athées, épicuriens, payens, juifs, mahométans et autres infidèles* (Antwerp, 1581); *Le mystère d'iniquité, c'est à dire, l'histoire de la papauté* (Geneva, 1611). Two volumes of *Mémoires,* from 1572 to 1589, appeared at La Forêt (1624–25).

See the life of Mornay written by his wife for the instruction of their son, *Mémoires de Mme. Duplessis-Mornay,* vol. i. in the ed. of *Mémoires et correspondances de Duplessis-Mornay* (Paris, 1824–25).

MORNING GLORY, the name given to the widely cultivated twining annual, botanically *Ipomaea purpurea,* family Convolvulaceae, native to tropical America. It bears broad, heart-shaped, short-pointed leaves and large funnel-form, blue or purplish flowers, 2 to 3 in. long. There are many races in cultivation, some with double flowers, and varying in colour. The hedge bindweed (*q.v.*) and the small bindweed (*Convolvulus arvensis*), especially when they become injurious weeds, are called wild morning glory. (*See* Convolvulaceae.)

MORNY, CHARLES AUGUSTE LOUIS JOSEPH, Duc de (1811–1865), French statesman, was the natural son of Hortense Beauharnais (wife of Louis Bonaparte, and queen of Holland) and Charles Joseph, comte de Flahaut (*q.v.*), and therefore half-brother of Napoleon III. He was born in Paris on Oct. 21, 1811, and was registered as the legitimate son of Auguste Jean Hyacinthe Demorny, described (inaccurately) as a landowner of St. Domingo. The comte de Morny, as he was called by a polite fiction, passed through the staff college, and served in Algeria in 1834–35 as aide-de-camp to General Trezel, whose life he saved under the walls of Constantine. In 1838 he established a beetroot-sugar industry at Clermont in Auvergne. Soon there were few great commercial enterprises in Paris in which he had not an interest. He sat in the Chamber as deputy for Clermont-Ferrand from 1842 onwards, and was heard with respect on industrial and financial questions. He was admitted to the intimate circle of Louis Napoleon, and he helped to engineer the *coup d'état* of Dec. 2, 1851. After six months of office as minister of the interior, he resigned. He now resumed his financial speculations, and when in 1854 he became president of the Corps Législatif, he used his official rank to assist his schemes.

In 1856 Morny was sent as special envoy to the coronation of Alexander II. of Russia; he there married Princess Sophie Troubetzkoi. In 1862 Morny was created a duke. Morny's influence with the emperor was very great, and his liberal traditions gave him influence with the leaders of the opposition. He died in Paris on March 10, 1865.

See F. Loliée, *Le Duc de Morny et la société du second empire* (1909) and his *Extraits des mémoires de Morny: Une Ambassade en Russie 1856* (1892).

MORO, ANTONIO (*c.* 1512–1575), otherwise known as Sir Anthony More, the eminent portrait-painter, was born at Utrecht in 1512, according to some, but in 1525 according to Karl van Mander in his *Het Leven der Schilders*. He studied his art under Jan Schoreel and after making a professional visit to Italy he commenced to paint portraits in the style of Hans Holbein. His rise to eminence was rapid. In 1552 (or 1542?) he was invited to Madrid by the emperor, Charles V. Two years afterwards he was in London painting the portrait of Queen Mary for her bridegroom, Philip II. of Spain. This picture is his masterpiece, and is preserved in the Prado museum at Madrid. For it an annual salary and, as some suppose, the honour of knighthood were conferred upon him. From 1555–59 he lived in Utrecht. In Aug. 1559 Moro accompanied King Philip to Spain, returning to Utrecht in 1560, in which year his portrait was painted by Jan Schoreel, now at the Antiquarian Society in London. He then entered the service of the duke of Alva at Brussels and died at Antwerp in 1575. His portraits are full of individuality, and characterized by firm drawing. The gallery at Braunschweig and the collections at Althorp and Petworth contain important works by the master.

MORO ("Moor"), a name given by Spaniards to the people of Sulu, an island and an archipelago between Borneo and the Philippines, on account of their religion; but although the Moros are Muslims they were formerly Hindu in part, while the aborigines, probably of Dayak affinities, are traditionally related to have worshipped tombs and stones of various kinds (*see* ASIA, *Farther*), and one genealogy starts with a prophet who sprang from a bamboo. Besides Malays of Minangkubau (*q.v.*), Bugis (*q.v.*) from the Celebes, Samals from Johore, and Ilanuns from Mindanao have settled in Sulu, and the population has been mixed further by innumerable importations of slaves from all the islands in the Philippines, and in Sulu itself there is a traditional division of the slave population into red-, white-, black-, and blue-eyed in the four quarters of the island. The Moros have legal codes drawn up in Arabic and are like other Malays renowned for piracy, fighting, and love of independence.

See Saleeby, *Studies in Moro History,* etc., and *The History of Sulu* (Ethnological Survey for the Philippines), IV. (1908).

(J. H. H.)

MOROCCO (MAROC), a country of Northern Africa, which forms with Algeria and Tunis a large geographical unit, the Djezira-el-Maghrib (Isle of the West) of the Arab geographers, the Barbary of the Europeans; it lies between 35° and 29° N. lat. and between 10° and 1° W. long. Morocco is bounded on the north by the Mediterranean, on the north-west by the Atlantic ocean, on the south by the Sahara, on which side there is no frontier nor definite boundary, on the east by Algeria. On the Algerian border, the treaty of 1845 between France and Morocco fixed the frontier over only about 100 km. from the sea to the point called Teniet-es-Sassi; beyond that there was merely an indication as to which tribes and ksurs or villages were Moroccan and which Algerian; in the Sahara all delimitation was considered superfluous. From this absence of definite boundaries and from the fact that France did not claim the natural frontier of the Muluya many difficulties have arisen. They were brought to an end by the establishment of the French protectorate over Morocco in 1912, and the question has lost much of its interest. The total surface of Morocco included within a line drawn through the Algerian frontier, Beni-Abbes, Tamgrut and the course of Wad Draʻa is 519,980 sq.km. or 203,117 square miles. (French zone, 415,000 sq.km.; Spanish zone, 104,600 sq.km.; international zone of Tangier, 380 sq.km.)

Physical Geography.—From the point of view of structure and relief, one may distinguish three great divisions; (1) the coastal massifs which border the Mediterranean, separated from the Atlas system by the depression of the Sbu and its right bank affluents; (2) the plains and plateaux of western Morocco; (3) the Atlas and its various chains towards the Sahara.

(1) The coastal massifs, almost unknown until recent years, have now been explored; they correspond, from the political point of view, with the zone of Spanish influence. They comprise three regions, the Jebela in the west, the Rif in the centre, and the Garet on the east. The western portion of the coastal massifs, as far as the valley of Wad Nkur and the Bay of Alhucemas, belongs to the Alpine fold system; crystalline and Palaeozoic rocks outcrop on the coast; then comes a much folded axial zone, made up chiefly of Liassic and Nummulitic limestones; finally there is a frontal zone of southward-directed overfolds which constitute the Pre-Rif. The chains are arranged in an arc of a circle, and form the counterpart of the Betic Cordillera (Sierra Nevada), to which they are related geologically in spite of the break at the Straits of Gibraltar. The higher summits lie between Chechaouen and the valley of the Nkur (Jebel-Tiziren, 2,500 metres). The country is dissected by deep ravines which give it, in places, a chaotic aspect. The slopes towards the Mediterranean are sharp, and the rivers rapid. The height of the chains, added to their exposure to the westerly wind, produces a marked contrast between the Jebela, moister and more fertile, and the Rif, where the vegetation is scantier. The coast, as usual in the Mediterranean, is mountainous and cut into arc-shaped bays; on the Straits of Gibraltar are Tangier, Ksar-es-Serir and Ceuta; between Ceuta and the Nkur lie the bays of Tetuan, of Badis (Peñon de Velez) and of Alhucemas. To the east of Wad Nkur the folds are well marked and the structure of the country much more simple; the dryness increases, and in the Garet the steppe reaches nearly to the coast. To the east of Cape Tres-Forcas lies the Bay of Melilla, near to which stretches the sebkha of Bou-Erg, then comes the bay sheltered by the Cap de l'Eau, beyond which lie the Zaffarine islands, not far from the mouth of the Muluya.

(2) The plains and plateaux of western Morocco stretch from the Atlantic to the foot of the Atlas. They include two different regions: El Gharb and El Huz, or the ancient kingdoms of Fez and Marrakesh. El Gharb has a varied relief, the influence of the coastal massifs extending as far as Fez and the massifs of Zarhun and Zalagh; the hills of El Gharb frame the alluvial plains of the Lukkos and the Sbu, on the estuary of which stand the ports of Larache and Mehedia respectively. The great east to west depression which links Algeria and Morocco by Ujda, Taza, Fez and Meknes, and which separates the coastal massifs from the Atlas, opens on the Atlantic by the plain of the Sbu; it is the corridor of Taza, an important feature of the geography of Morocco. The coast is flat, bordered with dunes and marshes. The Sbu, rising in mid-Atlas under the name of Wad Guigo, receives near Fez the Innauen, which brings it the waters of the corridor of Taza; then the Werra, which drains the southern slope of the coastal massif, lastly the Wad Mikkès, Wad Rdom and Wad Beht, left bank affluents. In its lower course the Sbu meanders and spreads among the marshes or *merdjas;* it has an average discharge of 40 cubic metres (minimum 13 cubic metres); it is tidal as far up as Kenitra and more or less navigable to Mechra-bel-Ksiri. The triangular stretch of country between the Atlantic coast from Rabat to Cape Guir and the Atlas constituted the Moroccan *meseta,* the subsoil of which is formed of anciently folded Archaean and Palaeozoic rocks incompletely covered by thin layers of Secondary and Tertiary age. The ancient rocks in the form of dissected schists and granitic bosses, dominate the region of the Zaër and of the Zemmour, which stretches along the left bank of the Sbu between Meknes and Rabat, the same structure continues farther east in the plateau of Ulmès and in the region of the Zaïan as far as the upper valley of the Umm er Rbiʻa. The retreat of the sea having taken place in successive stages, more and more ancient terraces are found as one penetrates the interior, as the altitude increases from 100–150 metres to 600–700 metres. The coastal plain (country of the Shawuja, of the Dukkala and of the Abda), 60 to 80 km. wide, is very fertile, especially the black clay lands called *tirs;* further from the sea one passes gradually to the steppe. Then cultivation begins again at the foot of the Atlas, thanks to irrigation. The rivers of the *meseta* run in a small number of ravines deeply dissecting the plateau. The Bu-Regrag, reaching the sea at Rabat is unimportant. The Umm er Rbiʻa, on the contrary, is the largest river of north-west Africa; rising in mid-Atlas, it runs at first in a deep narrow tectonic valley as far as Khenifra.

then crosses the plain of Tadla, receives the Wad-el-Abiad and the Tessaut, both rising in the high Atlas, encases itself deeply from Mechra-ben-Abbu to Bu-Lauan and reaches the sea at Azimur; its average discharge is 60 cubic metres, minimum 35 cubic metres. The much smaller Tensift drains the plain of Marrakesh; its left bank affluents, the Wad Rdat, Wad Reraïa, Wad Urika and Wad Nfys, bring it the drainage of the high Atlas. The coast of the *meseta* is extremely monotonous and even, and is, in general, edged with dunes with several shallow lagoons. The surf is very strong, and before the French protectorate there were only open roadsteads.

(3) The Moroccan Atlas (*see* ATLAS) is bounded on the north by the plains and plateaux of the Atlantic slope and by the corridor of Taza; on the south it slopes down towards the great furrow of the Wad Dra'a, beyond which stretch the platforms of the Sahara. It is usual to distinguish three chains of the Moroccan Atlas running south-west–north-east; the high Atlas, flanked on the north by the mid-Atlas and on the south by the anti-Atlas; the two latter being virgations of the high Atlas. The mid-Atlas lying between the Moroccan *meseta* and the *meseta* of Oran is, in general, only slightly folded; under the name of mid-Atlas are included very different regions, to the west of Ulmes, an Archaean peneplane dissected by erosion, to the east of Ulmes Jurassic limestone plateaux covered by recent Pliocene and Quaternary eruptive rocks (country of the Beni Mtir and of the Beni-Mgild), and, lastly to the south and the east, the chain properly speaking, which dominates the valley of the Muluya (3,800 metres at Mussa-ou-Salah). The mid-Atlas, where snows are abundant, is the chief source of water supply of Morocco; from it flows the Sbu, Wad Beht Bu-Regrag, Umm er Rbi'a; inhabited by large Berber confederations, it is also the stronghold of resistance. In the angle formed on the east by the mid-Atlas and high Atlas lies the upper valley of the Muluya, a high plain 1,500 to 1,700 metres in altitude, which merges on the east into the Moroccan Dahra, itself continued in the steppes of the province of Oran. The chief affluent of the Muluya is the Mellulu; it diminishes owing to evaporation in the steppe-land, in some seasons its discharge is abundant, in others the stream is nearly dry; the average discharge at Gercif is reckoned as 6 cubic metres. The high Atlas is divided into two parts, separated by the Tizi-n-Telremet (Tizi is the Berber word for "pass"). In the west are both primary and tertiary folds; schists and porphyrics predominate. To the south of Marrakesh rise the highest peaks in Morocco and in the whole of North Africa; Tubkal (4,225 metres), Wenkrim (4,173 metres), Likumt (3,906 metres); this great chain forms a barrier separating two distinct zones and proving a serious obstacle to communications. To the east of the Pass of Teluet or Pass of the Glaoua (2,600 metres) crossed by the road from the Dra, the Atlas seems to be composed mainly of Jurassic limestones; the outlines are softer, though the altitude is still about 3,000 metres, rising to 3,745 metres in Jebel Aïachi. To the east of the Tizi-n-Telremet (2,200 metres), crossed by the road from Fez to Tafilelt, the Atlas dies down and breaks up into several series of heights separated by plains, and it eventually joins the Sahara Atlas of Algeria. To the south of the high Atlas, a transverse chain, the Sirua (3,000 metres) joins the high Atlas to the anti-Atlas; it is a volcanic massif with crystalline substratum. The anti-Atlas (2,000 metres) has a distinct individuality only between the Sirua and the Atlantic, on the east it is scarcely a plateau, little higher than the surrounding country. The valley of the Sus is framed by the high Atlas, the Sirua and the anti-Atlas. East of the Sirua the drainage is to the Dra'a, which receives the Wad Dades; after the great elbow which it makes south of Tamgrut, it receives only intermittent feeders. The Wad Ziz, which receives the Todgha, called Ferkla and Gheris in its lower course, ends in Tafilelt. These Saharan wadi coming down from the Atlas are marked out by ribbons of irrigation-culture and by oases.

Climate.—The climate of Morocco is a Mediterranean one, modified by the Atlantic. The climate is more favourable than that of the rest of Barbary because the country is bathed by two seas and its high mountains keep the snow longer than elsewhere. The temperature is equable and quite cool for the latitude on the west coast; at Mogador the January mean is 61·5° F and the August mean 72·3°. Towards the interior the climate rapidly becomes more continental, with increased winter cold and very great summer heat; at Fez the January mean is 50° and that of August 80·6°. The rainy season is from October–November to April–May; it becomes shorter and less severe as one goes south towards the belt of the trade-winds. The mean annual rainfall is 829 mm. at Tangier, 494 at Rabat, 391 at Casablanca, 404 at Mazagan, 360 at Mogador; on the coast the dew is very abundant. Towards the interior the rainfall diminishes (Marrakesh, 279 mm.), but it is higher on the western slopes of the mountain massifs. The country of the Jebala, the western mid-Atlas, receives the highest rainfall; the regions of Meknes and of Fez, the corridor of Taza, open to the wet westerly winds, also have abundant precipitation (Meknes 555 mm., Fez 537 mm., Taza 600 mm.). Eastern Morocco, on the contrary, cut off from the moist winds by the great chains, is less favoured (Melilla 481 mm., Ujda 357 mm., Berguent 157, Beni-Unif 154, Bu-Denib 130). Snow falls several times a year at altitudes of above 1,000 metres and disappears from the high peaks only at mid-summer.

Vegetation.—The vegetation reflects the diverse influences of the climate; it is clearly Mediterranean in character; in the south a certain number of plants from the Canaries are found. The presence in the south-west, from Umm er Rbi'a to Wad Noun, of the argana (*Argania sideroxylon*), which belongs to the family Sapotaceae, is a remarkable botanical peculiarity. In the mountains, the vegetation takes on a more northerly character, many central European species and a certain number of Alpine plants occurring there. The well-watered regions are covered by forest except where it has been destroyed by man, as is the case in the plains of the west. The dominant species are oaks and conifers. The cork-oak constitutes the great forest of Mamora (125,000 hectares); in the mid-Atlas there are fine cedar forests (150,000 hectares); the evergreen oak, the *Zen* oak, the thuya and the juniper, are widespread. The argana forms a widely-spaced growth, a kind of forest-steppe. The forest passes into maquis, this into steppe, grassy when the rains are sufficient, and the steppe into desert. The fauna also is Mediterranean; the lion has disappeared, the panther and the macaque are common, as are also the jackal and the fox (fennec). Antelopes (gazelles) are numerous.

Population.—The indigenous peoples of Morocco are Berbers; they call themselves *Imaziren.* The Berber name covers very different human types; the most widely-spread seems to be akin to that of the southern Europeans (Ibero-Ligurian race); there are also amongst them Hamitic elements and some blond peoples whose type resembles the Nordic. There may be several successive layers of Berbers. There are three great groups of Moroccan Berbers, which differ from one another in language, race type and customs; the northern or Rif people, who inhabit the coastal massifs, the central or Berber group, who inhabit the mid-Atlas, and the southern or Chleuh group, who live in the high Atlas and in the Sus. In the plains the Berbers have adopted the Arab language and the Muslim religion, but Morocco, on account of its geographical situation, has been less influenced than Tunisia and Algeria from the eastern Mediterranean; tribes coming from Egypt and Asia have reached Morocco slowly and with difficulty, and the great chains of the mid-Atlas and high Atlas have proved effectual barriers, so that Arabs are met with only in the eastern steppes near the Algerian frontier. About half the indigenous population of Morocco speaks Berber dialects. The natives other than the town dwellers are divided into nomads and sedentary; mode of life has no connection with race, for many Berbers are nomads, especially in mid-Atlas; they have store-castles called *agadir,* for their harvests. Morocco has about 100,000 Jews, amongst whom may be distinguished the old established Jewish settlers and the Spanish Jews (*Guerush Castilla*). The slave trade has introduced a large number of Sudanese, who have influenced the complexion of the populations of the south.

Before the establishment of the French protectorate, there was a distinction in Morocco between the *bled-makhzen,* the region

in which the sultan had succeeded in making the natives pay tax and accept his *kaids*, and the *bled-siba*, which evaded his authority. The two regions had uncertain and fluctuating boundaries, the extent of the *bled-makhzen* depending on the varying powers of the sultan, and at times being reduced to the immediate neighbourhood of certain towns. The Berbers, jealous of their independence and lacking social classes among themselves, were, in general, impatient of any authority; they remained under tribal organization and were administered by small local assemblies called djemaâs; there was a permanent state of war between the tribes.

According to the census of 1926, the French zone of Morocco numbers 4,229,000 inhabitants; there are about 600,000 in the Spanish zone and 72,000 in the international zone, giving a total of about 5,000,000. The population is most dense in the plains of the west, El Gharb and El Huz, and on the border of the mountain massifs, the regions with a great altitude not lending themselves to permanent habitation. The neighbouring regions of the Sahara and of Algeria, except in the very limited areas where irrigation-culture is possible, permit only the low density, characteristic of nomad lands. There is a certain number of important towns; the chief are Marrakesh (pop. 149,263), Casablanca (106,608), Fez (81,172), Rabat (38,044), Meknes (29,930), Safi (26,914), Sali (20,965), Ujda (19,976), Mazagan (19,159), Mogador (18,401). In the Spanish zone Melilla has a population of 52,000, Tetuan 43,000, Ceuta 40,000, El-Ksar 40,000, Larache 20,000. Tangier, in the international zone, has 56,000 inhabitants.

In 1907, apart from the ancient Spanish possessions, there were not more than 5,000 Europeans in Morocco, of whom 4,000 were in Tangier. European immigration has been very rapid since the establishment of the protectorate. In the French zone there are 104,712 Europeans. But this population is, up to the present, essentially urban. Casablanca has 34,984 Europeans, Rabat 13,916, Ujda 8,780, Meknes 4,923, Kenitra 3,901, Marrakesh 3,652, Fez 3,559. Casablanca, in particular, which was only a poor hamlet before the French protectorate, has had an extremely rapid growth. Marshal Lyautey planned the European towns on the best hygienic and aesthetic lines, while respecting the native settlements. The rural population of European extraction is, up to the present, represented by about 2,000 colonists, living on their land and numbering with their families 5,000 to 6,000. Of the 104,712 Europeans in the French zone, 74,558 are French (including 8,335 French subjects and persons formerly under French protection), and 30,154 foreigners (15,141 Spanish, 10,300 Italian, 4,713 Europeans of various origin). To the Europeans of the French zone must be added about 100,000 Europeans, nearly all Spanish, in the Spanish zone (Melilla 30,000, Ceuta 25,000, Tetuan 8,000) and 15,090 in the zone of Tangier (of whom 9,000 are Spanish and 4,000 French).

Products.—Morocco is essentially an agricultural country. Of 500,000 sq.km. about 100,000–150,000 are cultivable, and 25,000–30,000 are effectively cultivated. The regions most favourable to agriculture are El Gharb, the valley of the Sbu, the provinces of the Shawiya and of the Dukkala, the districts of Meknes and of Fez and the valley of the Werra. The natives cultivate chiefly cereals and trees. The cereals grown are hard wheat (six to seven million quintals), barley (seven to eight million quintals), maize (one million quintals), sorghum (300,000 quintals). The natives also grow beans, lentils, chick-peas, flax, hemp, coriander and cummin. The Berbers, like all Mediterranean peasants, are essentially orchard-growers; the chief fruit trees are the olive, the fig, the orange, the pomegranate and the almond. The most important olive groves are in the districts of Marrakesh, Meknes, Fez, Wazzan, Shishawen and the Werra. The almond is grown chiefly in the district of Marrakesh and of the Sus, the orange at Tetuan and Larache, the walnut in the high Atlas. In the Sahara the main cultivation is that of the date-palm; the chief oases are those of Tafilelt and of the valleys of the Ziz, the Todgha, the Gheris, the Ferkla, the Dra'a and the Sus. The natives are stock-raisers; cattle are reared chiefly in El Gharb and the Zaïan (two millions in the French zone), sheep chiefly in the Tadla (nine millions). To these must be added goats (three millions), horses 200,000, especially fine in the Abda and the Chiadma, mules, and, in the Saharan region, camels.

In order to increase production, it is necessary first to intensify cultivation where it already exists, which could be effected, especially in the case of the cereals, by preliminary ploughing and by *dry-farming;* by the use of machinery and manures—by better methods of pruning fruit trees and of raising cattle and sheep. In the second place, it is necessary to increase the cultivated area, which, before the establishment of the protectorate, was extremely limited, owing to insecurity, to the absence of communications and to prohibition of exports. Finally, new crops might be introduced: bread-wheat (700,000 quintals), potatoes and castor-oil are spreading, as well as market gardens (13,000 hectares). It does not seem profitable to develop the growth of the vine to any extent in Morocco, for it would be difficult for it to compete with the products of France and Algeria; cotton, on the contrary, tried particularly at Berkane in eastern Morocco, seems susceptible of some extension. Experiments have been made in the growing of flax for fibre (up to the present it has been grown only for linseed), of sisal and of sugar-beet. Many plans for irrigation works, which would greatly increase the agricultural wealth, are being carried out; they affect chiefly the Umm er Rbi'a, the Sbu, Wad Beht, the Muluya, and the torrents of the high Atlas.

Agricultural progress is linked with that of the European colonization. It has become possible for Europeans to acquire property only since the establishment of the protectorate. The system of registration of land has somewhat reduced the chaotic conditions of native proprietorship (65,000 hectares registered). Land held in common by a tribe is inalienable. Demesne lands may be sold and form lots of large, medium, or small colonization. There are no free grants of land, and purchasers are under obligation to utilize the land bought. From 1918 to 1928 the office controlling agriculture has allocated, under these conditions, 190,000 hectares, in 1,100 lots. Altogether, the area owned by Europeans is 644,000 hectares, of which 608,000 are in French hands; but only a little of this is cultivated in European fashion. Forests occupy 1,900,000 hectares; their chief product is cork. The value of the fishing of the Moroccan ports is nine million francs.

Magnificent deposits of phosphate of lime, the exploitation of which has been reserved to the Moroccan Government, have been discovered; they are superior to those of Algeria and Tunisia, and are practically illimitable in quantity. They are worked in the district of Wad-Zem, near Tadla, at Kurigha and at El-Borudj; exploitation began in 1921, with 8,000 tons and now reaches 1,400,000 tons. Fine iron ores (haematite) are worked in Spanish Morocco, near Melilla in the district of the Beni-bou-Ifrur (250,000 tons per annum). An important deposit of manganese at Bu Arfa, west of Figig, is being exploited. Iron has been noticed in several other places, notably near Kenifra, lead and molybdenum in the high Atlas, zinc, copper and tin. Borings have been made for petroleum, notably near Petitjean; a small coalfield is being worked at Kenadsa, near Colomb-Bechar, on the Algerian frontier, and another has been found at Djerada, south of Ujda; but Morocco is still poor in mineral fuels.

Native industry is essentially home-industry; in spite of the encouragement it has received, it can barely survive European competition except in the making of carpets and Turkish slippers. The chief European industrial establishments are flour-mills, oil-mills, electric power stations and manufactories of implements.

Communications.—Morocco possesses 5,000 km. of good motor-roads, which link the ports and connect them with the two capitals of Fez and Marrakesh and with Algeria. During the World War of 1914–18, a network of military railways (of 0·6 metre gauge) was built, which greatly aided pacification and trade. This network is being gradually replaced by normal gauge lines, but it is still used for military operations in districts which are newly pacified, and as an adjunct to the ordinary railways in the other parts. The railways with normal gauge (1 metre 44) include: (1) The line from Tangier to Fez, opened in 1927; it is 310 km. long, of which 15 are in the Tangier zone, 91 in the Spanish zone and 204 in the French. (2) The line from Casa-

blanca to Fez runs through Rabat, Kenifra, Petitjean and Meknes; it is 322 km. long, of which 111 are on the Tangier–Fez line, which it joins at Petitjean. (3) The line from Casablanca to Marrakesh, finished in 1928, 250 km. long; at Ber-Rechid a branch line of 135 km. goes to Wad-Zem and to the phosphate workings. To complete essential arterial lines in Morocco the 0·6 metre line from Fez to Ujda must be replaced by one of normal gauge. A minerals line is being built from Bu-Arfa to Ujda. In the Spanish zone narrow-gauge lines connect Larache to El-Ksar (36 km.), Ceuta to Tetuan (41 km.), Melilla to San Juan-de-las-Minas and to Tistutin (50 km.).

A harbour is being built at Tangier, on the Mediterranean coast; to the ancient ports of Ceuta, Melilla and the Zaffarines the Spaniards have recently added that of Villa-Sanjurjo in the Bay of Alhucemas. On the Atlantic coast, the harbour of Larache, at the mouth of the Lukkos, has been improved. At Casablanca a new embankment 2,000 metres long, has been built in water 12 metres deep, to shelter the deep-water basins in which ships can unload at the quays; there are special installations for phosphates; Casablanca has 80% of the trade of the French zone (1,824,000 tons). Less important alterations have been, or are being, made at the other ports, which are, from north to south: Mehediya and Kenitra, ports of the Sbu, one at the mouth, the other on the river; Rabat, at the mouth of the Bu-Regrag; Fdla, a little fishing port; Mazagan, Safi and Mogador, which share the export trade of south Morocco and the trade of Marrakesh, and Agadir, the port of the Sus.

The external trade of the French zone of Morocco, which was 95 millions of francs in 1910, 222 millions in 1913, 1,269 millions in 1921, had risen to 2,644 millions in 1927 (imports 1,793 millions, exports 851 millions), representing 2,302,000 tons of merchandise. The difference between the amount of imports and exports arises from the fact that Morocco imports its tools and has not yet fully developed its production, and this difference tends to decrease. The chief imports are sugar (278 millions), cotton goods (210 millions), tea (92 millions), fluid fuels (84 millions), postal packages (80 millions), machinery of various kinds (80 millions), motor-cars (70 millions), iron and steel goods (50 millions), coal (42 millions). The chief exports are phosphates (161 millions), cereals, wheat and barley (175 millions), eggs (82 millions), skins (76 millions), wool (70 millions), almonds (49 millions), linseed (22 millions), sheep (20 millions), cattle (16 millions). France is responsible for 1,562 millions of the trade of Morocco (imports 1,124 millions, exports 438 millions). Great Britain has 268 millions (imports 194 millions, exports 74 millions), Spain has 169 millions (imports 22 millions, exports 147 millions) and the United States 115 millions (imports 100 millions, exports 15 millions). Trade in the Spanish zone reaches 111 millions of pesetas (imports 94, exports 17), the share of Spain being, imports 52 millions and exports 15 millions. The trade of the zone of Tangier realized 175 millions of francs (imports 146, exports 29), the share of France being 87 millions.

(A. BE.)

Defence.—Morocco cannot be said to possess an army in the modern sense of the term, but the tribesmen are seldom lacking in arms and ammunition, and the physical features of the country, with its difficulties of communication, favour their resistance to invaders of their territory. Constant wars, offensive and defensive, have been waged against Spanish possessions on the coast (*see* SPAIN: *Army*), and also, offensive and defensive, against the French, at first in Algeria (1844) and of late in Morocco. An approach to a regular army was formed by certain hereditary troops provided by the Maghzen tribes, the Bolchara (blade), Udaia (mulatto), the Ashragah and Ashrardah (white), the Gaish, Malchhaznia (mixed), all these being horsemen. The infantry (Askaria) were for the most part rough levies. The old army has now dwindled down to a Sultan's body-guard.

Since the latest Riff war, the French Resident General has controlled the military forces in the French zone, which consist of French and French colonial troops, reinforced by various native levies. Provision was made in 1927 for an army of 85,525, including 2,820 officers in Morocco. The Tangier zone is demilitarized. Pending the establishment of a proposed gendarmerie, order is maintained by a force of 780 native *tabors,* under French and Spanish control. The forces in the Spanish zone are similar to the French. Details are given under SPAIN: *Colonial Forces.* (G. G. A.)

HISTORY

Numerous archaeological remains, in particular a series of remarkable megalithic structures, prove the high antiquity of human occupation in Morocco. But the earliest historical records relating to this region are those of Hanno's *Periplus,* which mentions that Carthaginian colonies were planted along the coast. In the last century B.C. Moroccan Berbers are found supplying troops to Pompey or Sertorius, and later, under Augustus, they became incorporated in the Roman province of Mauretania (*q.v.,* and also AFRICA, ROMAN). But the Roman province reached only to the Bū Ragrāg, on which Sala, now Salli, was its outpost; Volubilis, near Mequinez, of which impressive remains are still visible, being its principal, if not its only, inland city. In the fifth century A.D. the country became subject to the Vandals and its fortunes form part of the general history of North Africa.

The coming of the Arabs under 'Oqba ('Okba) in 682 was a turning point in this history, though it was not till 20 years later that his successor, Mūsa ibn Nōsair, undertook a successful expedition as far as Tafīlālt and the Dra'a. The force of 10,000 Arabs and Egyptians with whom Tariq (Tārik) ibn Zāid held the Tangier district in 710 was trebled by the enrolment of the Berbers, who enabled him next year to invade Spain. But in 739 the Moroccan Berbers successfully revolted, setting up their first independent ruler, Maisara. Their kinsmen in Spain followed suit with equal success, and though subdued for a time, they retained their independence in certain parts till the 11th century, when, as masters of Granáda, they subjugated their implacable foes, the Arabs; and finally, under the Murābti and Muwāḥḥadi dynasties, conquered all Mohammedan Spain.

The recorded history of the Moorish empire commences with the settlement near the Roman ruins of Volubilis in A.D. 788 of Idrīs the elder (Idrīs b. Abdallah), one of the fugitive descendants of Mohammed during the struggles between rival claimants of the caliphate. Islām had then been established in these parts for 80 years, and Idrīs and his son, Idrīs II., the builder of Fez, united the Berbers into a kingdom. Their line controlled a limited portion of northern Morocco for nearly two centuries, in part supplanted by the Miknāsā in 922, until displaced by the Maghrāwā in 988. These two dynasties were exterminated in 1061 by Yūsef I. (bin Tashfīn), founder of the Murābti dynasty of Berbers (Almoravides), who annexed the remainder of Morocco and Tlemçen. Their principal existing monument is the city of Marrākesh. In 1149 the Murābti power was overthrown by another religious leader, 'Abd el Mumin at the head of the Muwāḥḥadi horde (*see* ALMOHADES), under whom the Moorish empire reached its zenith at the close of the 12th century. It then included, in addition to the Murābti realm, what now are Algeria, Tunisia and Tripoli, extending to the frontier of Egypt, which they were prevented from occupying by the rise of Saladin. Before the middle of the 13th century they had been driven out of Spain, and had lost all but what is now known as Morocco, whence, between 1217 and 1269, they were ousted by the Beni Marīn (Marinides). (*See* ALMORAVIDES and ALMOHADES.)

Beni Marīn Period, 1213–1524.—The new dynasty differed from the two which had preceded it in being frankly part of a Berber tribe, the Zenāta, who carved out a kingdom for themselves. Having assisted the Murābtis and Muwāḥḥadis respectively at the battles of El Arcos (1195) and Las Navas (1212), the defection of their amīr on that occasion offered an opportunity for Abd-el-Haḳḳ, the son of their general, to attempt the over-

throw of the reigning house. At first the Beni Marīn professed allegiance to Tunis, where the Hafsis, a branch of the Muwāḥḥadis, had thrown off the Moorish yoke and secured acknowledgement in northern Morocco and parts of Spain. But they were soon in a position to proclaim complete independence, and by the time that Abu Bakr, the third son of Abd-el-Haḳḳ to succeed him, died, in 1258, they held sway over all that is now known as Morocco, and 1269 saw the death of the last Muwāḥḥadi prince.

On the death of Abu Bakr there succeeded Yākūb II., one of the few amīrs of Morocco who have left a name for just administration and for philanthropic undertakings. Although of strict religious habits, he displayed no bigotry, studying philosophy, and entering into friendly intercourse with Europeans, whom he encouraged to trade with Salli. In 1261, 1275 and 1277–79, he undertook successful expeditions to Spain, and again in 1284, this time, in alliance with Alphonso of Leon, against his rebel son Sancho. But Alphonso dying during the struggle, Yākūb found himself master of his country, and Sancho had to acknowledge his suzerainty. All Mohammedans within his realm were freed from all taxes, and all the Arabic manuscripts of the country—13 loads—were despatched to the college Yākūb had built in Fez.

But Yākūb did not live to reap the benefits of his conquest, which were enjoyed by his son, Yūsef IV. (1286), who was courted by his father's old foes, entering into amicable relations with Tunis, Egypt, Arabia and the neighbouring European States. With the contemporaneous Beni Zeiyan dynasty of Tlemçen, sworn foes of his house, however, he was still at war when stabbed (1307) in the new town of Tlemçen, which he had built while conducting a siege of the old town. A second siege was begun in 1335, and Tlemçen fell in 1337 to the fourth ruler of the dynasty, Ali V., Abu 'l Hasan, better known as "The Black Sultan." Unsuccessful in his invasion of Spain and Tunisia, Ali had eventually to abdicate in 1351 in favour of his rebel son, the famous "Abu Ainān," Fāris I., who, during a short reign recovered Algeria and Tunisia.

The Beni Marīn were soon driven back, till a few years later Tlemçen alone remained to them, and this they held only till 1359 (*see* TLEMÇEN). Thereafter their empire became habitually divided between rival claimants, and the Portuguese began to obtain footholds on the coast. (B. M.; K. A. M.)

The Wattasi Dynasty.—The Wattasi dynasty which succeeded the Beni Marīn was short lived (1471–1548), the reign of its founder, Sa'id III. "El Wattass," and of his son Mohammed VIII., "the Portuguese," being marked by the conquest of Granada by Ferdinand and Isabella the Catholic (1492), the first expulsions of the Moors from Spain (1502) and the first conquests of Spain and Portugal in North Africa (Melilla, Peñon de Velez, and all the Atlantic ports, except Salle-Rabat). Tetuan was founded by the Moorish refugees from the Continent, who also brought back to Rabat and Fez the Andalusian taste for fine monuments.

The Sa'adi Dynasty.—As a reaction against the conquests of the Christians, a popular and religious movement gave their chance to a new family of "Sharifs," or nobles, more or less of Arab descent (as contrasted with the native Berber), and more or less related to Mohammed by the female side. The Sa'adi dynasty (1550–1668) rose in the Dra'a district, on the Sahara slope of the Atlas. They established themselves independently in Marrakesh from 1524, and their first act was to launch a *jihad,* or "holy war," against the Portuguese. By the end of the 16th century, they had reconquered most of the Atlantic ports.

El Dehebi and the Makhzen System.—After Abd-el-Malek—who perished at the famous "battle of the three kings," together with King Sebastian of Portugal, and Mohammed XI. whom he had deposed,—Ahmed IV. "El Mansur," "the Victorious," also called "El Dehebi," "the Golden," conquered Timbuktu, and brought back great riches (especially slaves and gold, whence his name) from the Sudan. He also proved to be a good administrator, in so far, at least, as the *Makhzen* system of government can be considered as good. It consisted principally in "pitting" certain tribes against the rest (*Bled es-Siba*), by exemption from taxes and tithes;—a doubtful procedure of course, but which finds an explanation and excuse in the geographical features of the country, in the natural anarchy of perpetually warring tribes, and in the fundamental opposition—which can be traced all through the history of Morocco—between the settled urban population and the nomads. "El Dehebi" was also a great builder, erecting, among other monuments, the marvellous pavilion, containing the tombs of the dynasty, in the palace of El Bedi, at Marrakesh, which ranks to this day as one of the most wonderful works of art of Northern Africa.

His most remarkable successor was Zidan, who reigned 20 years (1608–28), and also employed a number of European artisans in the palaces he constructed, or completed.

The Filali.—A fresh outburst of fanaticism partly provoked by the friendship for Europeans shown by Mohammed XIII. (1636–54), the last but one of the Sa'adians, but particularly inflamed by a certain number of *marabouts* (Islamic "saints"), who have always played a great part in the political and religious movements of North Africa, favoured the ambitions of a new dynasty. The Filali or Hassani,—Berbers,—also (more or less) of mixed Arab descent, sprang from one of the oases of Saharan Morocco, the Tafilalt. Their first representative, Mohammed XIV., captured Fez in 1649; though the dynasty only established themselves in Marrakesh (the home of their predecessors) in 1668. The dynasty is still on the throne.

Moulay Ismail, "The Bloodthirsty."—The two brothers of the founder, Rashid II. (1664–72), and especially Moulay Ismail, "the Bloodthirsty" (1672–1727), solidly established their power. Ismail,—though amply deserving his surname,—had the parts of a real sovereign. After his long reign of 55 years he left Morocco, notwithstanding many revolts, a more united empire than it has been ever since, until the French Protectorate. This was due principally to his body-guard (which exists to this day; though its *rôle* is no longer the same) of Negro Slaves (*Abids*) whom he recruited and settled close to his capital, Meknes,—and distributed in *kasbahs* (forts) throughout the country, furnishing them with negro wives, and giving a special position to their sons,—a selection of whom were each taught a craft,—and who were bound to him besides by a special religious tie: an oath on a copy of the book of *hadith* (sayings of Mohammed), by El Bokhari. Whence another name of the body-guard: the Bokharis. He also employed a foreign legion of renegades. Many hundreds of sons and countless daughters were born to him in a harem rivalling that of Solomon, for which he even asked a French princess of royal blood, Mademoiselle de Conti, a daughter of Louis XIV. by Louise de Lavallière (1699).

His death was followed by a period of disorders which only really ceased under Mohammed XVI. (1757–90).

European Intercourse and the Salli Rovers.—Ever since the 16th century commercial relations between Morocco and Europe have been maintained. Though expelled from the other Atlantic ports conquered by her at the end of the 15th century Portugal kept Mazagan up to the year 1769. Ceuta and Melilla were retained by Spain after the loss of her other settlements. She had given Tangier up to England in 1663. Moulay Ismail, who had reconquered Larache from the Spaniards, retook Tangier in 1683. Notwithstanding the piratical raids of the famous Salli rovers (and other pirates) and the many indignities to which thousands of Christians,—sailors, merchants, peasants and even women being often kidnapped on the Spanish or French coasts, even as far as Devon and Cornwall,—were subjected as slaves in Morocco itself, economic intercourse never ceased; and it was considered of sufficient importance to pass over the supplementary humiliation of foreign envoys being received on foot and bareheaded by mounted sultans under umbrellas. On the other hand, certain treaty privileges were conceded to foreign merchants, the coming of whom was encouraged by certain sultans at least This was the origin of certain rights confirmed by treaties which survived into the 20th century and became, of late years, the source of many difficulties between the foreign Powers themselves. The Government of Louis XIV., which always took a resolute stand against the Turkish corsairs on the Algerian coast

(Algiers was bombarded three times between 1682 and 1687), also despatched a fleet to Salli. A treaty of commerce was signed with Moulay Ismail on the occasion of the first embassy he sent to France (1682). During the first half of the 18th century, Dutch and English trade was to the fore; the latter profiting greatly by the warehouses established in Gibraltar after its taking by Sir George Rooke in 1704. But French influence reasserted itself by the bombardment of Larache and Salli (1765), and a new treaty (1767) was concluded, confirming that of 1682 and giving the French Consuls precedence over those of other nations.

THE 19TH CENTURY

The Conquest of Algeria.—With Abd-er-Rahman II. (1822–59), a new phase begins, to which the conquest of Algeria by France in 1830 soon gave a particular leaning. The Moors renounced all claim on the kingdom of Tlemçen, a remnant, with the kingdom of Fez and the kingdom of Tunis, of the vast Empire of the Moroccan Almohades. But infractions of the agreements then entered into led to the war of 1844, in which Marshal Bugeaud distinguished himself at the battle of Isly. A bombardment of Salli in 1859 secured for the French the settlement of various claims. War with the Spaniards followed. Tetuan was taken in 1860.

British Influence in Morocco.—The remainder of the reign of Mohammed XVII. (1859–73) was uneventful. That of his successor, El Hassan (1873–94), was marked by interior troubles, of which he gradually but with difficulty became master. Since 1856, British influence in Morocco had been on the ascent, owing to the talent and the prolonged embassy (1844–85) of Sir Drummond Hay. He was not in favour of opening Morocco to European influences, and tried to limit the "protection" accorded, especially by Spain and France, to certain Moorish subjects. The Madrid conference (1880) gave an exactly opposite result. The possibility of registering "protected" Moors in foreign consulates was extended from the towns to the country and foreigners acquired certain property rights. Great Britain thereupon partly changed her policy. A special British Embassy (1892) tried to obtain an extension of the rights of foreigners, but failed. The following year, incidents in the "Presidios," between the Rifis and the Spaniards, ended in an important Spanish expedition (25,000 men); and the treaty of 1894, while only conceding insignificant frontier rectifications to Spain, involved the sultan in the payment of some £650,000 indemnity.

Abd-ul-Aziz IV.—The same year saw the ascension of Abd-ul-Aziz IV. (1894–1908), whose chamberlain, Si Ahmed-ben-Musa, became Wazir and exercised the real power till his death in 1900. The young sultan, who was desirous of reforms, and had a taste for foreign arts, sought especially, under the advice of his mother, a Circassian slave, the friendship and advice of Great Britain. But he became the prey of schemers and speculators who pandered to his worst traits and squandered his treasure. The *Makhzen* treasury had to be refilled, the taxes were increased and recovered, as usual, at the point of the sword and the natural consequence was local revolts, two of which were important, that of Jelali Zarboni, nicknamed *Bu Hamara* ("the Man on the Ass") on the Algerian frontier, and the rebellion of a local sharif, Mulai Ahmed-es-Raisuli, in the district of Tangier.

The Franco-British Treaty of 1904.—As a result of the entente cordiale, and as a counterpart of France "disinteresting" herself from Egypt, Great Britain gave up her ideas of intervention in internal Moroccan affairs (April 8, 1904). Article 2 is important:

"The French Government declares that it is not its intention to change the political status of Morocco. On the other hand, H.B.M.'s Government recognizes that it belongs to France notably, as a Power conterminous with Morocco to a vast extent, to see to the tranquillity of the country, and to lend it her assistance for all the administrative financial and military reforms it is in need of." (Translated from the French text.)

The principle of the liberty of commerce was guaranteed for thirty years; to be prolonged by periods of five years if not denounced (art. 4). No fortifications to be erected at Tangier (art. 7; liberty of the Straits of Gibraltar). In a last article, the Governments agreed to "give one another the aid of their diplomacies" for the carrying out of the clauses of the treaty.

The Franco-Spanish Conventions.—On Oct. 3, 1904, a treaty was signed between Spain and France. Both declared that they were firm partisans of the integrity of the Moroccan empire. Spain recognized France's "special rights," as already stipulated in the Franco-British treaty of April. On the other hand France recognized Spain's special rights on the northern coast of Morocco. They were not defined in the treaty, but in a secret arrangement which was not revealed until 1911, and were equivalent to the creation of two "zones of influence." Two other secret arrangements followed (1905 and 1907), concerned with the police of the ports, the joint execution of public works, contraband, the customs dues, and the monetary situation (creation of a State Bank).

The Intervention of Germany.—In 1905 came Germany's intervention. She had several times complained of being "ignored" in Morocco, though her direct and special "interests" may perhaps be questioned. Russia's discomfiture in the Far East in her war with Japan, gave Germany her opportunity. The German emperor's spectacular disembarkment at Tangier (March 31, 1905) was followed by conferences with the ministers of Abd-ul-Aziz. As a result, an official proposal by the *Makhzen*, inspired by Germany, for the calling of an international conference, was launched, and France consented to the principle.

M. Delcassé, who had been principally instrumental in the preceding treaties, was none the less forced, under German pressure to resign office (June 6, 1905); an event of far-reaching reaction on French public opinion; and which created the impression (several times renewed since by the Casablanca deserters affair; the Agadir incident, etc.), that Germany was bent on picking a quarrel. During the Algeciras negotiations themselves, she obtained from Abd-ul-Aziz the concession of the building of the port of Tangier, which had already been promised to a French company, and a loan of 10 million marks with a Berlin bank, in violation of an engagement taken with the French banks at the time of a loan contracted with them in 1904.

The Algeciras Conference (1906).—The Algeciras Conference began on Jan. 16, 1906. In accordance with the 1904 treaty, the British delegates gave their loyal support to France; while Austria played the part of a "brilliant second" on the German side. The general Act was signed on April 7, 1906, and accepted by the Sultan on June 18. It consecrated the economic internationalization of Morocco, under the sovereignty of the sultan. Commercial equality for all was, once more, stipulated; but France's "special position" was recognized by Germany herself. The only two particular advantages obtained by France were: (1) the allowance of a predominant part in the capital of the Moroccan State bank, on account of the monetary advances already made by her to the *Makhzen;* (2) the sharing with Spain of the police of the Moroccan ports. The diplomatic corps in Tangier was put in charge of the creation of the administrative and financial reforms stipulated at Algeciras (Moorish police in the ports; State bank; acquisition of land by foreigners; control of the Customs administration; impartial adjudications—without reference to the nationality of the bidder,—of public works and supervision of the public works administration itself; etc.).

Beginnings were difficult. The country was far from tranquil. In May 1906, a Frenchman was murdered at Tangier. At the end of the same year, a Franco-Spanish naval demonstration had to be prepared, on account of the activities of Raisuli against Europeans in the suburbs of Tangier;—of which the famous "Kaid" Sir Henry Maclean himself, colonel of the sultan's bodyguard, was afterwards a victim, and had to be ransomed by the British Government for £20,000. One of the Sultans' *mehallas* finally put into flight the brigand-functionary.

French Landing at Casablanca in 1907.—On March 19, 1907, Dr. Emile Mauchamp was murdered at Marrakesh; and Ujda occupied by French troops until satisfaction should be given to the French demands. On July 30, nine European work-

men, employed in the Casablanca harbour works, were killed; and the passage of a detachment landed from the cruiser "Galilée" having been opposed, and all the Europeans attacked, the town was bombarded. (The occupation of the Shawia district followed, the tribes opposing Generals Drude and d'Amade, and the fighting being heavy.) By June 1908 the district became quiet and the original force of 15,000 men was reduced.

In September 1908 the incident of the six deserters from the Foreign Legion (three of whom were Germans) followed in Casablanca. They had a safe-conduct from the German consul, but were arrested by a French patrol. The German Government demanded that France should express her regret before the facts were fully established. The case was submitted to the Hague Court of Arbitration, which decided substantially in favour of France (May 1909). But the incident created some excitement in France and in Germany. Nevertheless an agreement was reached between the two countries on Feb. 8, 1909, in which France re-affirmed her will to maintain economic equality and Germany her pursuance of economic interests only, recognizing France's special political claims.

Mulai Hafid.—In the meantime, Abd-ul-Aziz had been defeated by his brother Mulai Hafid (1908), who had been proclaimed sultan by the Ulema of Marrakesh the year before. But Hafid's power remained weak. The Rif tribesmen revolted against Spain, who was obliged to send an army of 50,000 men to reduce them to submission (Nov. 1909).

In 1910, Mulai Hafid obtained a loan of £4,000,000 chiefly from France, who had also given the new Sultan a proof of her moderation by the promise of gradual evacuation of the Shawia country, and even of Casablanca, against the creation of a *Makhzen* police force under French instructors and the payment of an indemnity by the Shawia tribes. An agreement on somewhat the same terms was signed with the *Makhzen* by Spain in Nov. 1910. But a revolt had already begun round Fez in October. It continued to spread and the town was besieged by the neighbouring tribes in March 1911. All the consuls called for help; and the sultan himself asked for it. A French expedition released the town. In June, Spain occupied El Qsar and Larache (El Araish).

The Agadir Incident and the Franco-German Treaty of 1911.—On July 1, came the explosion of the Agadir bomb; the German gunboat "Panther" suddenly appearing before the town, "in order to protect German interests." War seemed imminent; but Great Britain stood firmly by the Entente, and announced her formal opposition to Germany's obtaining political rights in Morocco. Complicated negotiations between France and Germany followed; and ended in the treaty of Nov. 4, 1911. France obtained from Germany a certain number of rights—to occupy, by agreement with the Sharifian Government, points where the maintenance of order might render the occupation necessary; and to be the Sharifian Government's obligatory medium in its foreign relations. A Resident General might be appointed, if necessary, at Fez and France should have the right to control the Sharifian finances in order to ensure the payment of foreign debts, etc.

In exchange, the principle of economic equality for all, notably for the concession of mines and railways, etc., was reaffirmed. In a letter annexed to the treaty, a large slice of French Congo was handed over to Germany, to the indignation of a part of French opinion which could not see the link between the two questions. On the other hand, though the word "Protectorate" was not formally used in the body of the treaty itself, a near equivalent could be found in it; and, by a second letter, Germany agreed not to oppose it, if circumstances rendered it necessary.

The French Protectorate and the Franco-Spanish Agreement.—As soon as the treaty had been ratified by the two parliaments, M. Regnault was sent to Fez, and the Franco-Moroccan treaty of March 30, 1912, was signed, by which Mulai Hafid agreed to a certain number of reforms, equivalent to a Protectorate, which was accepted by the Powers. Negotiations with Spain ensued, for the putting into force of the secret treaty of 1904. The new Convention was signed on Nov. 27 and contained a few modifications as to the frontier of the Spanish zone, which follows the Muluya from its mouth to near Meshra 'Klila. Thence turning west, it runs north of a line reaching to Jebel Mulai bu Shota (the Riff) and thence, striking toward the north-west, to the Atlantic, and containing El Qsar and Larache. A Khalifa (Deputy) represents the sultan at Tetuan, where the Spanish Commissioner-General resides. The Spanish Protectorate extends over a zone of about 18,300 sq.m., with an estimated population of 460,000 (1923). The question of the Ifni enclave in the south was also settled. Tangier (*q.v.*) and its neighbourhood (about 100 sq.m.) constitute a special internationalized zone.

The Protectorate was followed by a revolt at Fez (April 17, 1912), in which 13 French officers, 40 soldiers and 13 civilians were killed. General Lyautey was appointed resident-general and took up his post on April 27, 1912. Mulai Hafid, whose collaboration could not be counted upon, retired on Aug. 12, and was succeeded by his brother, Mulai Yusef. The history of General (now Marshal) Lyautey's administration is a remarkable example of France's colonial policy. Internal difficulties were not wanting. The tribes around Fez remained unsettled, especially in the Taza "corridor" leading to Algeria. In the south, the revolt of El Hiba necessitated the occupation of Marrakesh (Sept. 1912) by General Mangin, who was to play such a conspicuous part in the World War. Fighting in Western Morocco continued for some months, but this district and that of Fez were occupied by the spring of 1913. The important strategic point of Taza was taken in May 1914, and Khenifra (centre of the unsubdued Zaïan tribes of the Tadla district), in June.

Morocco and the World War.—On the outbreak of the World War, the French commander received telegraphic orders from the ministers of foreign affairs and of war (July 27–28, 1914) "to reduce the occupation to the principal points on the coast," as "the fate of Morocco would be settled in Lorraine," and asking him to send all available men and material to the French front. Lyautey immediately dispatched 37 battalions and other troops; but refused to evacuate the interior. The tribes round Taza and the Zayan in the west promptly rose once more, but the three great *kaids* of the Atlas and the *bashas* of Tarudant and Tiznit, in the south, near Agadir, remained friendly. The Spanish zone was used by the Germans as a basis of active propaganda and action against the French Protectorate. Throughout 1915 and 1916 chiefs in German pay conducted a campaign along the Wad Wergha. But in May and June 1917 Abd el Malek was driven from Taza. In March 1917, El Hiba was severely defeated at Wijan, his force being dispersed in the following spring. The Tafilelt was definitely occupied at the end of 1917.

Military Operations After the War.—After the War the French continued their operations, taking the offensive now on one and now on another of their four fronts: the northern (Spanish zone, Djebala and Riff tribes); the Berber (Central Atlas); the front of the big *kaids* (round Marrakesh, the Glawi, M'tuggi, Gundafi); and the southern front (Kut Aissa, Tafilelt). By the end of 1923, the French zone was completely pacified. Lyautey's constant aim all through was the conquest of what he called "useful Morocco" (*le Maroc utile*), the last French operations being largely dictated by the need of gaining control of the "Water Castle" of the Central Atlas.

Abd el Krim and Spain (1923).—But Lyautey's military difficulties were not at an end. The Riffis, who, during the World War, had lavishly received arms, ammunition and money from the Germans against the French, turned, from 1919 onward, against the Spaniards. In 1921, Abd el Krim, the son of a Beni Uryaghel (Ouriaghel) chief, some time in the Spanish service, settled at Ajdir, at some distance inland from Alhucemas, stirred up resistance between that point and Melilla, and inflicted a terrible defeat on the army of General Silvestre. With the capture of an enormous amount of arms and ammunition, these Moroccan events led to a crisis in Spain, and, in Sept. 1923, the constitutional Government was replaced by a Military Directorship under General Primo de Rivera, who decided upon a general withdrawal; a courageous but difficult manoeuvre which was not accomplished

until the autumn of 1924. But the evacuation increased Abd el Krim's prestige, and on the other hand, the gradual occupation by France of the northern limits of her Protectorate caused some apprehension to the Riff chieftain.

Abd el Krim and France (1925–26).—In April 1925 Abd el Krim launched a furious attack on the Taza-Ujda roads; the tribes that remained faithful were massacred; Wazzan and Taza were threatened; but Lyautey, although his councillors were, it is said, in favour of a retreat, persistently refused to budge from Taza, just as he had refused to abandon the interior in 1914, thus saving Morocco for France a second time. A regular and severe campaign ensued. A rapid glance at a good map, enables one immediately to appreciate its difficulties. In July, Marshal Pétain was sent on a mission to Morocco while General Naulin took supreme command of the troops, under the high direction of Marshal Lyautey. But, on Aug. 22, Marshal Pétain returned to Morocco. A joint action of France and Spain was agreed upon, at a conference held in Madrid. On Sept. 8 a successful disembarkation of Spanish troops took place in Alhucemas bay and a junction was effected at Syah between the columns of the two countries. Winter suspended the general operations, which really necessitated quite different methods and material from those employed in European warfare, a practical point that appears to have been too often lost sight of. So the Riff "coup-de-main" continued. On May 30, however, 40,000 additional native troops having been recruited, Abd el Krim surrendered unconditionally at Taza to General Boichut, the French commander, and was sent in exile to Madagascar. (*See* ABD EL KRIM.) The French losses during the campaign amounted to 2,162 exclusive of casualties among native troops; but the monetary expense was great, and will be supported principally by Morocco itself (about Fr. 26,000,000).

Meanwhile, Marshal Lyautey had sent in his resignation to the French Government (Sept. 24, 1925), and was succeeded (Oct. 6) by M. Theodore Steeg, who had just been successful as Governor-General of Algeria. A new sultan, Mulai Mohammed, succeeded his father on Nov. 17, 1927.

THE PROTECTORATE

The Sultan and the Makhzen.—In accordance with Muslim law and traditions, the Sultan remains, not only the head and tutor of the whole Sharifian house, but the only legislator. His *dahirs,* countersigned by the Resident-General, are binding, as laws, even on the French residents and colonists in Morocco. His *Makhzen* (Central Government) is composed of the grand wazir, and the wazirs, or ministers of justice, domains, *habus* (land or houses the perpetual usufruct of which is given up by their owners for religious, charitable or public uses), and public instruction; and the presidents of the High Sharifian Tribunal and of the Tribunal of Appeal of the *Chraa* (Islamic law, as opposed to Berber custom).

The Pashas, Kaids, Kadis and the Berber Customs.—Outside their courts, pashas in the towns, and *kaids* in the country, represent the temporal authority of the sultan (as opposed to his religious authority, represented by the *kadis*), have also certain penal powers, and act as judges in cases where movables and commercial matters are concerned. His religious and judicial authority is vested in the *kadis,* local judges, who are in reality religious magistrates, the civil and family status (including inheritance) of a Muslim being regulated by the Koran. The judicial competency of the *kadi* has even been partly maintained in the matter of the acquisitions of landed property (art. 60 of the Act of Algeciras). Hence the importance of the Ministry of Justice. But when land has been *immatriculated* (*see* below), it falls under the new land laws and French jurisdiction. On the other hand, care was taken by Lyautey to preserve, as far as possible, among the Berber tribes, the customs (*izref*) to which they are deeply attached. Disputes as to personal status, property, etc., are settled by the *djemaas* (popular assemblies), according to custom.

The "municipalities" created by Lyautey, and in which the Moors and the French are given an opportunity of collaborating under the double guidance of the Pasha and a French "Civil Controller," have not been constituted on a uniform model (election of the Moorish members in the very important intellectual and commercial centre of Fez for instance; elsewhere, nominated, etc.). The authority of the *kaids* was not allowed the same play near the fighting front as in the south, where the three great feudal lords, the Glawi, the M'tuggi and the Gundafi (the last two died in 1928) wielded great local powers and were left free to use them. The *habus* (*see* above), or *wakfs,* an essentially Muslim institution, were respected but were reorganized. In 1912, owing to maladministration, the receipts of the *habu* ministry only amounted to Fr. 1,870,000. In 1926, they had risen to Fr. 9,000,000 with a cash balance of Fr. 3,000,000, relieving the Moroccan budget from the expenses relative to the salaries of a great number of religious professors in the *medersas;* of the numerous *fonctionnaires* of the mosques (*imams, khatibs, muezzins,* etc.); of the upkeep of the mosques themselves, and the *zauias,* mausolea, etc.

The Central Services.—The whole administration is under the authority of the "Commissaire, Résident Général" (decree June 11, 1912) assisted by a delegate to the *Makhzen,* and a secretary general of the Protectorate. The central administration, which is entirely concentrated at Rabat, comprises (1) the aforesaid general secretariat, to which are attached the following services: civil control, personnel, legislation, general administration, penal justice; and the special direction of native affairs and intelligence service (in the military zones); and the following "directions générales": (2) finance; (3) public works; (4) agriculture, commerce, industry and colonization (with the forest and the land survey and registration); (5) public instruction, fine arts and antiquities; (6) public health; (7) post, telegraph and telephone office.

The "Exterior Services"; the "Civil Controller."—The exterior services are in the hands of a staff of "civil controllers"—the pivot of administration, as is the district officer in British India, a sort of "Jack-of-all-trades of the Protectorate," omniscient, work-beridden, who must be informed (and inform the Rabat headquarters) of everything that is going on, advise and watch the *pashas, kaids* and *kadis,* know the "notables" and headmen, help the French colonists, audit the native provident societies, give his reasoned opinion on the roads and public works projected, keep an eye on the collecting of the taxes, secure harmony between the French and the Moorish population, etc. They are distributed among the civil regions (Ujda, Eastern Morocco), the Gharb (Khenifra), Rabat, the Shawia and autonomous circumscriptions (Doukhala, Mazagan); Abda (Safi); Shiadma (Mogador); Oued Zem, etc. There are four military regions (Marrakesh, Fez, Meknes and Taza). These regions generally correspond to the habitat of a leading tribe; and the tribal distribution itself is, in most cases, commanded by the physical features of the country.

The French Judiciary.—The French judiciary organization (which comes into play whenever Frenchmen or foreigners are concerned) comprises 12 peace tribunals, four tribunals (Casablanca, Rabat, Ujda and Marrakesh); and a court of appeal (with 10 magistrates), also at Rabat.

The Government Council and the French Taxpayer.—In order to secure "a constant and regular collaboration between the Government and French settlers in the country," the presidents and vice-presidents of the French chambers of commerce, chambers of agriculture and mixed chambers of both (according to the regions; 10 chambers in all), whose members are elected, assemble, every two months, at Rabat, for the Council of Government, to which the 7 Directors-General, above enumerated, belong. A third College of the Council was created in 1927. It consists of French citizens not belonging to the second College (Agriculture, Commerce and Industry); that is to say, the liberal professions (lawyers, doctors, pharmacists, etc.), French artisans and workmen, the functionaries and even the few *rentiers.* The first election took place on May 15–29, 1927. It was marked, as in Algeria, by political squabbles among Frenchmen; and so, probably, will not prove an unmixed blessing. On the other hand, it is difficult

to exclude from a participation in the Government, and especially in the examination of the taxes, any category of French citizens who pay them (and the indirect taxes, at least, are fairly heavy). The sitting takes places every two months. The reports on budget questions are often entrusted to the elected president of the chambers of commerce or agriculture. Not counting Tangier, there were seven French daily papers and 30 periodicals in Morocco, and three native papers in Arabic (1923).

Finance.—The 1928 budget amounted to Fr. 640,000,000; the annual debt charge, to Fr. 150,000,000. A new loan of Fr. 819,-800,000 was authorized by the law of March 22, 1928, with the guarantee of the French Government. The former loans (1914, 1916 and 1920) amounted to Fr. 986,000,000, out of which Fr. 770,500,000 have been expended. The new loan is mainly destined for the Fez-Ujda railway line, which is estimated to cost Fr. 800,000,000, Fr. 750,000,000 of which will be at the charge of the Protectorate. It will complete the 752 km. of normal gauge railway lines already exploited or under construction (besides 418 km. planned; and about 1,500 km. of narrow gauge) and constitute an Imperial Highway from Tunis to Casablanca. The Casablanca to Marrakesh line was opened in November 1928.

Public Instruction.—Public instruction is still behind-hand with the natives, as there were only, in 1926, 77 missionary schools with 5,612 pupils; but there was a beginning even with the girls, quite a revolution in the Maghreb (1,041 in 1926); There are also 5 special schools for the sons of the "notables"; 13 apprenticeship schools (461 pupils); and 2 colleges (204 pupils). The 34 Jewish primary schools had a far larger attendance (7,471 for a total Jewish population of 107,000) than the Moors' (6,879 school attendants in all for a population of 4,016,000). The European schools (primary, technical and colleges) had a school population of 21,570 in 1926. (Hi. Br.)

M. Steeg and Moroccan Prospects.—Under the prudent guidance of M. Steeg, the French Protectorate of Morocco gained assurance of a prosperous future. As in Algeria, he had great plans for *la politique de l'eau* (irrigation and water power), and the geographical conditions are better in Morocco. The Wazzan territory was pacified in the spring of 1927, and in December the Ida and other mountain tribes made their submission.

On Jan. 1, 1929, following the law passed by the French Chamber forbidding the extension for more than six months of the "special missions" of members of parliament, M. Steeg resigned and was succeeded by M. Lucien Saint.

MORÓN DE LA FRONTERA or **MORÓN** (anc. Arumi), a town of southern Spain, in the province of Seville; 32 m. S.E. of the city of Seville. Pop. (1920) 18,758. Morón occupies an irregular site upon broken chalk hillocks near the right bank of the Guadaira. It is connected by rail with Utrera. The chief public building of Morón is the large parish church, which dates from the 16th century.

MORON, deficient in intelligence, from Gr. *mōros*, "foolish."

MORONE, the name of two distinguished Italian painters, father and son, of the Veronese school. Of Domenico Morone (*c.* 1442–*c.* 1517) but few works have survived. The frescoes which he executed in San Bernardino at Verona (1503) and in the little church of San Niccolò di Tolentino at Paladon (now in the Museo Civico) are not well preserved. There are, however, two signed works which reveal him as a spirited painter of much grace and decorative quality. One is the large canvas of the Crespi collection, Milan, which was painted in 1483 for the Marquis of Mantua and illustrates the fight between the Gonzagas and the Bonacolsi. The other signed picture is a small "Virgin and Child" at Berlin. The National Gallery has two delightful small scenes at a tournament ascribed to him on stylistic evidence.

His son Francesco Morone (*c.* 1473–1529), after working as an assistant of his father, began work as an independent painter, and in 1495 produced the "Crucifixion" in the church of San Bernardino. His greatest work in fresco was the decoration of the walls and ceiling of the sacristy of S. Maria Organo with incidents freely adapted from Mantegna's "Camera degli Sposi" at Mantua. This work is one of the greatest monuments of local art. In the same church is an altarpiece (1503) representing the Madonna enthroned between two saints, a work fine in colour and design and of remarkable finish. Francesco's pictures are rare outside Verona. The Brera, Milan, has two interesting works. The National Gallery, London, and the Berlin museum each contain a picture of the "Virgin and Child."

MORONE, GIOVANNI (1509–1580), Italian cardinal, was born on Jan. 25, 1509 at Milan, where his father, Count Ieronimo Morone (d. 1529), was grand chancellor. His father, who had been imprisoned for opposing encroachments on the liberties of Milan by Charles V. (whom he afterwards cordially supported), removed to Modena. The son was educated there and at Padua. He was in 1527 nominated by Clement VIII. to the see of Modena, and consecrated in 1533 after a contest. From 1535 he was constantly entrusted by Paul III. with diplomatic missions. In 1542 he was created cardinal, and was further nominated protector of England, Hungary, Austria, of several religious orders, and of the *santa casa* at Loreto. With the cardinals Paul Parisio and Reginald Pole he was deputed to open the Council of Trent (Nov. 1, 1542), the place of meeting having been a concession to his diplomacy. The legates arrived on Nov. 22, but no council assembled. The death of Paul III. (1549) deprived him of a good friend. The views of the Reformers had spread in his diocese, and he was suspected of temporizing with them. He resigned his see (1550), reserving to himself an annual pension and the patronage of livings. Julius III., at the instance of the duke of Milan, gave him (1553) the rich see of Novara (which he resigned in 1560 for the see of Albano) and sent him as nuncio to the diet of Augsburg (1555), from which he was immediately recalled by the death of Julius (March 23). In June 1557 Paul IV. imprisoned him in the castle of St. Angelo (with others, including Pole and Foscherari), on suspicion of Lutheran heresy. The prosecution entirely failed, and Morone might have had his liberty, but refused to leave prison unless Paul IV. publicly acknowledged his innocence. He remained incarcerated till the pope's death (Aug. 18, 1559), and took part in the election of Pius IV. Ochino, in the twenty-eighth of his *Dialogi XXX.*, 1563, has a colloquy on the treatment of heretics, between Pius IV. and Morone, in which the latter maintains: "Errantes in viam revocandi, non occidendi." This really hits the position of Morone, a sincere Catholic, to whom persecution was abhorrent. He presided at the Tridentine Council from April 10 to Dec. 4, 1563. In 1564 he was reinstated in the see of Modena. On the death of Pius IV. (1565) he came near to being elected pope. He died at Rome on Dec. 1, 1580, and was buried at S. Maria sopra Minerva.

See J. G. Frick, "De Joanne Morono," in J. G. Schelhorn's *Amoenitates literariae*, vol. xii. (1730); "G. Moroni," *Dizionario di erudizione* (1847); N. Bernabei, *Vita del cardinale G. Moroni* (1885); M. Young, *Life and Times of Aonio Paleario* (1860); C. Benrath, in Hauck's *Realencyklopädie* (1903); G. Constant, *La Légation du Cardinal Morone, 1563* (1922).

MORONI or **MORONE, GIAMBATTISTA** (*c.* 1525–1578), Italian portrait-painter of the Brescian school, was born at Albino near Bergamo and became a pupil of Bonvicino named Il Moretto. His portraits are full of straightforward life and individuality, with genuine unforced choice of attitude, and excellent texture and arrangement of draperies; there is a certain tendency to a violet-tint in the flesh. Among his works may be mentioned—in the Uffizi Gallery, Florence, the "Nobleman pointing to a Flame," inscribed "Et quid volo nisi ut ardeat?"; in the National Gallery, London, the portraits of a Tailor, a member of the Fenaroli family, Canon Ludovico de' Terzi, and others; in the Berlin Gallery, his own portrait; other portraits are in the galleries of New York, Boston, Vienna, Munich and Milan. Most of his pictures are at Bergamo. He died on Feb. 5, 1578.

MOROSINI, a noble Venetian family whose two chief members were:

Andrea Morosini (1558–1618) was a famous historian and was entrusted by the Venetian senate with the task of continuing

Paolo Paruta's *Annali Veneti*, in Latin. His history of Venice was published by his brother in 1623, and translated into Italian by Senator Girolamo Molin (1782). Among his other works are: *Le Imprese ed espeditioni di terra santa, etc.* (Venice, 1627); *De iis quae veneta respublica ad Istriae oras gessit, etc.* (in the Corner-Duodo collection of mss.); *De forma reipublicae venetae* in ms. in the Bibliothèque Nationale in Paris. His life has been written by Luigi Lollin (1623), by Niccolo Crasso (1621), and by Antonio Palazzoli (1620).

Francesco Morosini (1618–94) was one of the greatest captains of his time. He fought against the Turks and the pirates, and after distinguishing himself at the battle of Naxos in 1650 he was appointed commander-in-chief of the Venetian navy. He conducted a series of successful campaigns against the Turks, but was recalled in consequence of the intrigues of his rival the Provveditore Antonio Barbaro (1661). But when Candia was attacked Morosini was sent to relieve it in 1667; the siege lasted 18 months, but Morosini was forced to surrender to save the surviving inhabitants. He was tried but acquitted of all blame, and on the renewal of the war with the Turkish Empire in 1684 he was again appointed commander-in-chief, and after several brilliant victories he reconquered the Peloponnesus and Athens; on his return to Venice he was loaded with honours and given the title of "Peloponnesiaco." In 1688 he was elected doge, and in 1693 he took command of the Venetian forces against the Turks for the fourth time; the enemy, which had been cruising in the archipelago, withdrew at his approach, so great was the terror inspired by his name. He died at Napoli di Romania (Nauplia) on Jan. 6, 1694.

MORPETH, town and borough, Northumberland, England, on the river Wansbeck, 17 m. N. of Newcastle on the L.N.E.R. Pop. (1931) 7,390. The manor of Morpeth is said to have been granted to William de Merlay soon after the Conquest and passed with the borough from his family to the earls of Carlisle, with whom it remains. The town is a borough by prescription and grew up round the castle attributed to William de Merlay. Nothing remains of the castle except the gateway. The valley of the Wansbeck above Morpeth is well wooded, and in it are fragments of Newminster Abbey, a wealthy 12th century foundation, and the ruins of a Norman castle and manor house of the 17th century. A peel tower of the 15th century is seen at Cockle Park. Local industries have included tanning, brewing, malting, iron and brass founding, and the manufacture of flannels, agricultural implements, and bricks and tiles. Charles II. incorporated the town in 1662, and under this charter the borough was governed until the Municipal Reform Act of 1835.

MORPHEUS, in Roman mythology, one of the sons of Somnus, the god of sleep. In Ovid (*Metam.* xi. 635), he calls up human shapes (*μορφαί*) of all kinds to the dreamer, while his brothers Phobetor and Phantasus assume the forms of all kinds of animals and inanimate things. It is, however, possible that Ovid misinterprets his name and that it really means "dark," *cf.* *ὀρφνός*. Whether he is a popular or a literary figure is uncertain.

See Jümpel in Roscher's *Lexikon, s.v.*

MORPHINE, the chief alkaloid of opium (*q.v.*), insoluble in water and ether. It is used in the form of its hydrochloride, sulphate, acetate and tartrate and in various non-official preparations such as dionin, heroin, glycaphorm and peronin. The preparations of morphine are incompatible with salts of iron, copper and mercury, also with lime water and alkaline earths and substances containing tannin. With ferric chloride it forms a deep red colour.

Morphine relieves pain and produces deep sleep. From opium it differs in being less astringent and constipating. No drug yet discovered equals morphine in pain-relieving power. The most frequent mode of administration is the hypodermic, on account of the extreme rapidity with which it is absorbed. In pain due to violent sciatica relief and even permanent cure has been obtained by the injection of morphine directly into the muscle of the affected part, and in the treatment of renal and hepatic colic, given subcutaneously, it will relieve the acute pain. A violent paroxysm of asthma may be arrested by the administration of morphine subcutaneously, but the practice should not be continued, as there is great danger in a chronic disease that the patient may become the victim of morphinism. Morphine is recognized as one of the most useful drugs in the treatment of eclampsia, early injection often arresting the fits. In hæmoptysis morphia is invaluable in quieting the patient and in the cough of phthisis minute doses are of service, though morphine is frequently better replaced by codeine or heroin, which check irritable coughs without producing narcotism. Its use in Bright's disease is dangerous, minute doses producing disproportionately great results. For the same reason it is not administered to children. In bronchitis with profuse expectoration it checks cough but also checks secretion; where cough is harassing small doses may be necessary to procure sleep, but it must be remembered always that renal disease is often accompanied by bronchitis. In the dyspnoea of advanced valvular disease of the heart morphine relieves the distress and restlessness, and induces sleep. It should, however, be withheld if the heart has undergone fatty degeneration. If given in excess the drug is eliminated by the intestines and kidneys. It is also excreted in the milk; hence the danger in the administration of large doses of morphine to nursing mothers. (*See* Poisons; for morphinism *see* Drug Addiction.)

Morphine-scopolamine anaesthesia was introduced in 1902 by Steinbückel. It has been used by some surgeons for the production of anaesthesia previous to the administration of ether or chloroform, but the use of the method is now more usually relegated to obstetric practice to produce the so-called twilight sleep (*see* Scopolamine).

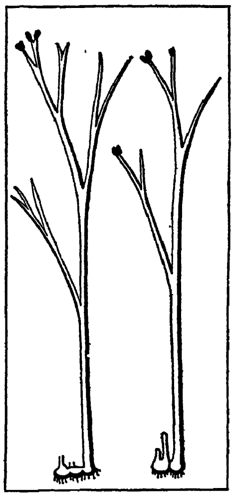
Physical and Chemical Properties.—Morphine, $C_{17}H_{19}O_3N$, crystallizes from alcohol in colourless prisms, containing one molecule of water, which is lost at 100° C. The anhydrous alkaloid melts at 254° C, and has a specific rotation of $[\alpha]^{23°}_{D} = -130.9°$ in methyl alcohol. It is sparingly soluble in most solvents, but dissolves in lime-water and alkalis owing to its acidic character, due to the possession of a phenolic hydroxyl group. (*See* Phenol.) It is also a monoacidic base forming salts, which are usually well crystallized. Many of these are manufactured for use in medicine but those most commonly used are the sulphate, $(C_{17}H_{19}O_3N)_2,H_2SO_4,5H_2O$, and $C_{17}H_{19}O_3N,HCl,3H_2O$, the hydrochloride, which forms colourless, silky needles from water. When morphine or its hydrochloride is heated with hydrochloric acid at 140° C under pressure, it is converted by loss of a molecule of water into *apomorphine*, $C_{17}H_{17}O_2N$, a substance which has lost the characteristic physiological action of morphine and has acquired that of a powerful emetic, for which purpose it is principally used in medicine. Morphine also yields a number of derivatives, in which its characteristic physiological action is retained in a somewhat modified form. Thus when the phenolic hydroxyl group of morphine is methylated, the alkaloid codeine (*q.v.*), $C_{18}H_{21}O_3N$, which also occurs naturally in opium, is produced. Other derivatives, analogous to codeine, have been made for use in medicine, such as ethylmorphine (dionin), benzylmorphine (peronin). Morphine can also be converted into a diacetyl derivative, known commercially as heroin. The third alkaloid of this group, thebaine, is of importance mainly on account of its chemical relationship to morphine and codeine, but is of no value in medicine, since in it the convulsant action feebly manifested in some of the derivatives of morphine is much more strongly developed.

MORPHOLOGY, a term used in zoology and botany to cover all those studies in which the centre of interest is the form and structure of an organism. It is thus the antithesis of physiology (*q.v.*).

The first step in morphology is to determine and record the

shape of a whole animal. This shape never exists as a permanent quality; it is constantly varying with the animal's movements even in the case of animals with a hard skeleton such as the lamellibranchs or the crustacea.

There is nevertheless in the vast majority of cases a definite plan visible at any time for each individual animal. The creature may be free-moving or it may be fixed to the ground either permanently or for the time being. It may have no axis of symmetry and be indefinite in shape like an amoeba, or it may be bilaterally symmetrical like a fish, or radially symmetrical like a star fish. It may like a sea anemone be apparently radially symmetrical but actually possess an underlying bilateral symmetry. Such symmetry as it possesses may be externally perfect, or it may be modified by differences in the development of similar appendages on the opposite sides, as in the case of the great claws of a lobster.



BY COURTESY OF PROF. LANG

A RECONSTRUCTION OF A VERY EARLY TYPE OF LAND-LIVING PLANT, LEAFLESS AND ROOTLESS

External Forms.—The external form of every animal must be such as to enable it to live under those conditions in which it is placed. Thus a study of the external shape of an animal can have little meaning unless it is coupled with an investigation of the function of the various structures and forms which it presents.

Quick movement of an animal either through water or air, whether in contact with a substratum or not, can only be achieved if the animal is bilaterally symmetrical, because only then, the animal moving in one direction, will the impulses which the animal receives from the activities of its muscles be symmetrically disposed so as to ensure a straight track. On the other hand an animal which lives constantly attached to the sea bottom in most cases receives its food from all directions or from above, and must be so designed that it can catch it with equal ease whencesoever it comes. Thus a radial symmetry is most suitable for a sedentary animal.

The analysis of the external form of a single animal can often be carried much further. The motion of a fish swimming in water is hindered by many factors, which have been disentangled by naval architects. Unless its shape conforms to a special geometrical figure, the "streamlined form," it will create eddies which absorb energy, it will produce bow and tail waves, and the water will exert a definite frictional resistance to motion, varying with the smoothness of the skin and with some other qualities. Thus it should be possible to predict the ideal shape for a fish. But this exact form will be unrealisable in actual life, because it is necessarily modified to secure stability, both when the fish is motionless, and also in the sense of maintainance of its course when swimming. Furthermore the needs of feeding and of taking in and expelling the water which is necessary for respiration modify the shape of the anterior part, while the hinder end is conditioned by the area and shape of the tail fin and the muscles which move it.

Thus any explanation of the shape of a fish is necessarily complicated, so many factors entering into it that anything more than a rough analysis is impossible.

But those features of the external form of an animal which have a directly adaptive significance are mere modelling carried out on a basis of fundamental structure which is in essence uniform throughout large groups of allied species.

Subcutaneous Structures.—An investigation of external form if it is to be at all satisfying involves an understanding of those structures which lie beneath the skin.

The skeleton and somatic muscular system are only significant in relation to their function of bringing about movements, either of the animal as a whole, or of the jaws and other organs for such special purposes as the capture of food. Theoretically there is a most efficient shape for each bone and each muscle in the body of a fish, but exactly as in the case of the external form this ideal is never attained, in part because few organs or parts of organs are so isolated that they can be exclusively devoted to one function unmodified by the impact of neighbouring structures, and in part because their fundamental architecture is determined, not by present needs, but by those of a chain of ancestors which may be very remote and very different in habits.

Thus any investigation of structure from a fundamental standpoint necessarily involves a comparison with that of other animals, which may be held to be relatives in the sense that all have been derived by evolution from some common ancestor.

Such a comparison between two similar animals of different sizes will reveal a whole series of proportional differences which depend simply on absolute size. Thus an organ like the ear fulfils exactly the same function in a domesticated cat and in a lion perhaps fifty times as heavy. In each animal it has to determine rotational movements of the head, to determine its position with respect to gravity, and to receive sounds and analyse them into their constituent tones over a certain range. These things are done satisfactorily by the ear of a cat and even more so by those of smaller animals such as bats, and there is no reason for which the size of the organ should be increased however large the animal may become. In fact the ear of a lion is only about three times the volume of that of a cat. But generally the size of an organ necessarily varies with that of the animal of which it forms a part, and varies in accordance with mathematical laws. For example the weights of two similar animals will vary as the cube of their linear dimensions, while the areas are only related as the squares.

Thus if the larger of two cats was a mere mechanical enlargement to twice the length of the other, its weight would be eight times as great, while the area of the transverse section of a legbone would be only four times as large, the pressure tending to crush it being twice as great for a unit area. Thus if there is to be the same factor of safety in the two cases the leg-bone of the larger animal must be thicker, so that its diameter will be $\sqrt{2^3}$ instead of $\sqrt{2^2}$; *i.e.*, instead of twice the diameter, it should be nearly $2\frac{3}{4}$ times as large.

Modifications in accordance with this law apply to all the organs of the body, to the lungs and alimentary canal, to the brain and spinal nerves as well as to the skeleton. But after allowance has been made for all such differences, there will still remain others which cannot be accounted for on mechanical grounds but represent innate characters of the two animals.

If the comparison be carried further afield, as it must be if the nature of the general plan of the structure is to be determined, fresh difficulties arise.

A comparison of a bird with a mammal will show a similarity of external structure in that each is bilaterally symmetrical, has a head, neck, trunk and tail, and two pairs of symmetrical appendages. But in the mammal the anterior pair are walking legs, in the bird they are wings. The problem which at once arises is whether it is justifiable to compare these structures with one another or whether they are *sui generis*.

This problem may be attacked in several ways which depending on different lines of reasoning should give consistent results.

Each appendage is covered with skin, which in the one case supports feathers, in the other fur, but as this skin is continuous with and of the same general character of that which coats the body it is clear that the differences between their qualities is not a special feature of the organ which we are discussing.

Below the skin in each case lies a series of bones and muscles, together with the blood vessels and nerves which are necessary for their maintenance and control.

In each case the skeleton consists of an articulated series of bones forming functionally a series of interconnected levers. The segment lying nearest the body is single, articulating with a cup formed by two bones which lie within the body; the second segment contains two bones lying side by side which at their outer ends articulate with a series of small bones, the wrist, beyond which lie in one case the bones supporting five fingers, in the other a strange bone with a slit dividing it incompletely along its length, which in turn supports others forming three axes. Thus

the proximal parts of the skeletons of the two appendages have a similar arrangement, while distally they differ considerably. The muscles, blood vessels and nerves show similar resemblances and differences.

MORPHOLOGICAL RESEMBLANCE OR HOMOLOGY

It is evident that the differences between those structures that lie distal to the wrist in the bird and mammal are associated with the different functions which they perform; in the bird they have to support the largest feathers of the wing, in the other they have to be divided into fingers so as to enable the animal to gain a firm hold on the ground over which he is walking. It thus seems to be legitimate to regard the two structures as members of a single category, despite their difference in function. The nature of this group can be made clearer by a comparison of the wing of a bird with the parachute of the flying lizard "Draco," which performs similar functions in that it supports the animal in the air. In Draco the parachute consists of a fold of skin stretched out by a series of delicate unjointed bony rods which project to its margin. These rods are the animal's ribs each articulating independently with the backbone. There is in fact no structural resemblance between the two organs despite their functional similarity. The recognition of this difference between resemblances of structure and resemblances of function arose gradually and was only firmly established and defined by Richard Owen in 1843, who applied to morphological resemblance the term "homology" and to functional or "physiological" resemblance, "analogy." In Owen's words, Homology "as the same organ in different animals under every variety of form and function (*e.g.*, fore limbs of Draco volans and wings of a bird)"; Analogy "as a part or organ in one animal which has the same function as another part or organ in a different animal (*e.g.*, parachute of 'Draco' and wings of a bird)."

This distinction between homologous and analogous structures is fundamental; it underlies all morphological studies whether they are concerned with comparative anatomy in the old sense, embryology, or the classification of animals.

Interpreted in evolutionary terms homologous structures are those which can be traced back to a single structure in the common ancestor of the animals compared. Thus if we knew the ancestors of a bird and a mammal for a sufficient distance back, we should see a steady divergence of structure of the fore limb, leading to the bird's wing and to the fore leg of a mammal. In fact the single fossil bird which is old enough to differ materially in structure from those now living, "Archaeopteryx," has three independent fingers agreeing in the number of their phalanges and in their general structure with the first three fingers of a lizard, and we have evidence that the very remote ancestors of a mammal had a similar structure. Thus an investigation of their history confirms the view that the two structures are homologous.

If homologous structures in different animals be derived by evolution from the same structure in an ancestor, it should follow that the mode in which they arise during the development is the same in each case, and a new criterion of homology becomes available.

The "Limb Bud."—In the case of the bird's wing and the mammal's fore leg the mode of origin is the same. In each there first appears a small swelling on the lateral surface of the trunk toward the ventral surfaces, and in each this "limb bud" is an outpushing of the skin by a mass of cells, some of which wander into the region, whilst others appear by the multiplication *in situ* of these cells. From them the bones, muscles and blood vessels are gradually formed, whilst the nerve fibres which supply them grow out into the developing limb from definite parts of those which pass as a regular series from the spinal cord to the muscles which lie between the ribs and to the skin.

The limb bud gradually grows longer, its end becomes enlarged and divided into lobes which finally become fingers. This process is identical in bird and mammal for a considerable time.

If we compare a mammal with a dogfish we find a general similarity in the plan of structure, but whereas in one we have two pairs of appendages, the legs, lying at the extremities of the trunk, in the other legs are absent but two pairs of fins lie in a similar position. At first the structures of these two appendages, leg and fin, seem totally different; one has a bony skeleton surrounded by muscles on all sides, whilst the other has a cartilaginous skeleton with the muscles lying only above and below it. The most obvious point of similarity is that in each case the nerves that supply the muscles come in the same way from the ventral branches of the spinal nerves. If we examine the mode of development of the two organs we find a similarity in that each appears as a limb bud, a fold of skin lying longitudinally and supported by a mass of cells, but whereas in the mammal the muscles arise from these cells, in the fish they grow down from the body musculature. Thus even embryologically there are differences between the two structures.

Nevertheless they are regarded as homologous, even although no real intermediates are yet known

This belief is founded largely on the identity of the nerve supply: it having been found that the evidence as to homology afforded by different classes of structures varies greatly in value.

But it is possible to carry the conception of homology much further; an investigation of the origin of the nerves supplying the fore limb shows that that structure, which is clearly homologous among the vertebrates, may lie at very varying distances behind the head; in a frog its supply comes from the actual second, third and fourth spinal nerves behind the head; in the extinct reptile "Elasmosaurus" it probably came from the 77th to the 80th nerves.

Thus different position in the body of an animal, whose body is in part or whole composed of a succession of similar segments is consistent with homology. But in general character, in mode of origin, and in the nature of their nerve supply, the fore and hind limbs of vertebrates are identical, and thus by an extension of reasoning may be held to be homologous, the homology being of a special nature called serial.

The criteria which may be used for the determination of serial homology between the parts of an individual are in essence identical with those used in discussions involving two distinct animals, identity of general relationships and embryological origin being those chiefly used.

Analysis of the Vertebrate Head.—Perhaps the most elaborate example of an analysis of structure depending on the determination of serial homology is that of the vertebrate head, first attempted successfully by J. W. van Wijhe. A long series of investigations has led morphologists to the view that the head of a vertebrate includes a series of segments, eight in number in most higher forms, which are homologous with one another and with the segments of the trunk. From this conception the prediction could be made that there must once have existed primitive vertebrates in which each segment contained a definite series of muscles, skeletal parts, nerves, blood vessels and gills either identical throughout the series, or exhibiting a gradation in structure from front to back. Such an animal has now been discovered in the fossil "lamprey" Cephalaspis, from the Upper Silurian. Such verification of a prediction by subsequent discovery is the best testimony to the value of the method by which the original prediction was made.

EXPERIMENTAL MORPHOLOGY

The actual structure of any organ in the body of an animal represents a compromise; in its fundamental plan it is determined by the nature of the ancestors of the animal of which it forms a part, while the details are determined by the function which it carries out and by the interference of neighbouring structures. The factors involved are so numerous, and interact so considerably that no analysis based on a comparison with similar forms can hope to be complete.

The correct scientific procedure in such cases is that of experiment; one and one only of the factors believed to influence the final structure is changed artificially in a known way, and the resulting changes investigated. Comparatively little work along these lines has been carried out; the field of work is open and should prove profitable. One aspect of such work has, however,

been largely exploited, the investigations commonly grouped together under the term experimental embryology.

Explanation of Structure-Changes.—These studies have had for their object an explanation of the succession of changes in structure which transform a fertilised egg cell into the body of a larva or an adult. To a very large extent they have been concerned with the earliest part of the process, the cleavage or segmentation stages, and they have succeeded in demonstrating that for many animals these parts of the whole process of development are pre-determined by the structure of the fertilised ovum, which, apparently uniform in many forms, must itself possess an elaborate and definite structure.

But some investigations, especially those of Speeman and his followers, carried into later stages have shown how in Amphibian embryos the course of development is controlled by definite localised parts of the animal, the "organisers," which take control, one after the other, until some organs become self-determining and can develop into their final structure in isolation. The whole of this work is strictly morphological in that it is the form and changes of form which are studied.

The structure of an egg, the events which are associated with fertilisation, and the nature of the zygote are investigated by cytologists, whose technical methods have all been designed to make visible in microscopical preparations the architecture of these bodies. The information so acquired is, however, difficult to relate to that which is inferred to exist in the zygote from the evidence afforded by experimental embryology, and only through the very indirect evidence of genetical research has it become established that the chromosomes, the most visible structures in the nucleus, possess a structure of elements, "genes," with a linear arrangement, which is directly associated with a developmental course which leads to the appearance of structures which exhibit an alternate or Mendelian inheritance.

The investigations of physiologists have made it certain that such elements of an animal's body as muscle and nerve fibres and the surface layer of all cells must possess an ordered arrangement of molecules, whose nature we may hope to discover by the methods of physics and chemistry. Thus in the end the study of biology will involve a morphology, not of organs, tissues or cells, but of molecules and electrons which form the mechanism whose functioning is life.

In philology, morphology is that branch of grammar which examines the form of words as well as the principles of word-formation and inflection. In general use the expression morphology has been extended to comprise the general laws of the grammatical structure of a language, *i.e.*, as synonymous with accidence.

(D. M. S. W.)

MORRILL, JUSTIN SMITH (1810–1898), American political leader and financier, was born at Strafford, Vt., on April 14, 1810. He was a clerk in a store at Strafford in 1825–28, and at Portland, Me., 1828–31, and was a merchant and then a farmer in his native town in 1831–55. He was elected to the national House of Representatives as an anti-slavery Whig in 1854, soon afterwards joining the new Republican Party, and served in the house from 1855 until 1867. From 1867 until his death more than 30 years later he represented Vermont in the Senate. In the house he was continuously a member of the ways and means committee and in the Senate of the finance committee of which he was chairman for nearly 20 years. Soon after entering Congress he became the acknowledged leader of the protectionists, and at the request of John Sherman, then chairman of the ways and means committee, he prepared a new tariff bill, which was introduced in the house in March, 1860. To this relatively conservative bill, which substituted in many instances *ad valorem* for specific duties, and was intended by its author to be a revenue as well as a protective measure, were added many amendments which made the bill more strongly protectionist, and in some cases were vigorously opposed by Morrill. The bill was finally passed by the Senate on Feb. 20, 1861, and was signed by President Buchanan on March 2 following. Morrill is probably best known as the author of the Land Grant Act passed on July 2, 1862, which provided for the foundation and maintenance of colleges "where the leading object shall be, without excluding other scientific and classical studies, and including military tactics (which had not been included in the original bill), to teach such branches of learning as are related to agriculture and the mechanic arts . . . in order to promote the liberal and practical education of the industrial classes in the several pursuits and professions in life." In 1890 Morrill introduced in the Senate the so-called "second Morrill Act," under which $25,000 is given annually by the Federal Government to each of the "land-grant" colleges. He died at Washington, on Dec. 28, 1898.

See William Belmont Parker, *The Life and Public Services of Justin Smith Morrill* (1924).

MORRIS (Morrison), **CLARA** (1849–1925), American actress, was born in Toronto (Ont.), and at the age of 17 joined a stock company in Cleveland, Ohio. Her first New York appearance (1870) was under Augustin Daly in an adaptation of Wilkie Collins's *Man and Wife;* and she won considerable success as Cora in *L'Article 47,* Camille, Miss Multon and similar emotional parts. In 1874 she married Frederick C. Harriott, and soon afterwards began to write novels and to contribute to magazines. She published her *Life on the Stage* in 1901, and *Life of a Star* in 1906. She died at New Canaan, Conn., on Nov. 20, 1925.

MORRIS, EDWARD PATRICK MORRIS, 1st Baron, cr. 1918, K.C.M.G. 1913 (1859–), Newfoundland statesman, was born at St. John's, Newfoundland, on May 8, 1859. Educated at St. Bonaventure's College and the University of Ottawa, in 1884 he was admitted a solicitor, and in 1885 was called to the bar. The same year he was elected to the legislature of Newfoundland as the representative of St. John's in the Liberal interest. From 1890 to 1895 he was acting attorney-general for Newfoundland, and from 1893 to 1906 he was a director of the Newfoundland Savings Bank. In 1898 Morris left the Liberal party and was leader, first of the Independent Liberals and later of the People's party (1908–19). In 1902 he became attorney-general and subsequently Minister for Justice. He was knighted in 1904. In 1909 he became Prime Minister, retaining this office until 1918, and representing Newfoundland at various Imperial and other conferences. He was sworn of the privy council in 1911 and in 1917 was a member of the Imperial War Conference. Lord Morris edited an edition of the Newfoundland law reports from 1820 to 1905, usually called *Morris's Reports.*

MORRIS, GOUVERNEUR (1752–1816), American statesman, was born in the old Morrisania manor house, in what is now the city of New York, on Jan. 31, 1752. He graduated at King's college (now Columbia university) in 1768, studied law, and was admitted to the bar in 1771. An extreme aristocrat in his political views, he distrusted the democratic tendencies of the Whigs, but a firm belief in the justice of the American cause led him to join their ranks. Morris served in the New York provincial congress in 1776–77, and after the congress had become the "Convention of the Representatives of the State of New York," he served on the committee of that body which prepared the first draft of the State constitution. He served in the Continental Congress in 1777–79, and was enthusiastic in his support of Washington. In 1778 he was selected chairman of the committee to treat with Lord North's conciliation commissioners, and as such presented the famous report, adopted by a unanimous vote of Congress, which declared that the recognition of independence must precede any negotiations for peace.

He settled in Philadelphia as a lawyer, and in Feb. 1780 he published a series of essays on finance, in which he criticized the issue of legal tenders, denounced laws passed for the benefit of the debtor class, and urged the people to tax themselves for the common good. From 1781 to 1785 he was assistant to Robert Morris (*q.v.*), superintendent of finance. In 1782 he prepared an elaborate report on the coinage, suggesting the use of the decimal system and of the terms *dollar* and *cent.* With some modifications introduced by Jefferson, this plan constitutes the basis of the present American system. Morris was one of Pennsylvania's representatives in the Constitutional Convention of 1787, and took an active part in the debates. His influence was weakened, however, by his cynicism and by his ultra-aristocratic

views. He was instrumental in securing the executive veto and in defeating the proposal that the legislature should elect the President. He also gave able support to the nationalist and anti-slavery factions in the convention. He was a member of the committee of revision selected to draft the Constitution in its final form. In 1787 he returned to New York to live.

He went to France in Feb. 1789 on private business, and remained abroad for nine years, passing most of the time in Paris, London and the German capitals. He was appointed U.S. minister to France in 1792, and was the only representative of a foreign country who remained at his post throughout the Reign of Terror; but his ill-concealed attitude of hostility to the Revolution gave offence, and in return for the recall of Genêt, at the request of the United States, the French government, in 1794, asked for the recall of Morris. Business and pleasure, however, still detained him in Europe until 1798, when he returned to New York, resumed the practice of law, re-entered politics and sat in the U.S. Senate as a Federalist from 1800 to 1803. As early as 1801 Morris became interested in projects for improving the communication between the Hudson river and Lake Erie, and from 1810 to 1816 he was chairman of the board of canal commissioners, which prepared plans for the Erie canal. He was bitterly opposed to the War of 1812, and openly advocated the formation of a northern confederacy to escape the rule of the "Virginia dynasty." He died at Morrisania on Nov. 6, 1816.

His half-brother, LEWIS MORRIS (1726–1798), a signer of the Declaration of Independence, was educated at Yale, served in the Continental Congress (1775–77) and went on a mission to the western frontier in 1775 to win over the Indians from the British to the American side. He joined the Army as brigadier general of militia in June 1778, and served in the New York Senate (1777–81 and 1784–90).

See *The Diary and Letters of Gouverneur Morris* (1888), edited by Anne Cary Morris; Jared Sparks, *Life of Gouverneur Morris* (1832), the first volume being a biography and the second and third containing Morris's miscellaneous writings and addresses; and Theodore Roosevelt, *Gouverneur Morris* in the "American Statesmen" series (1888).

MORRIS, SIR LEWIS (1833–1907), Welsh poet, was born in Carmarthen, in 1833. His great grandfather, Lewis Morris (1700–65), had been a well-known Welsh poet and antiquary. He was educated at Sherborne school and Jesus college, Oxford. He won the chancellor's prize for an English essay in 1858, was called to the bar in 1861, and elected hon. fellow of his old college in 1877. He practised for 20 years as a conveyancing counsel, retiring from active legal work in 1881. He was knighted in 1896. *Songs of Two Worlds* (1872, 1874 and 1875) showed a fluent gift of versification, and *The Epic of Hades* (1876–77) has passages of undeniable force and effect. Among his other books were *Gwen* (1880), *Songs Unsung* (1883), *Gycia* (1886), *A Vision of Saints* (1890), *Idylls and Lyrics* (1896) and *The New Rambler* (1906). He died at Carmarthen on Nov. 13, 1907.

MORRIS, ROBERT (1734–1806), American financier, a signer of the Declaration of Independence, was born in Liverpool, England, on Jan. 31, 1734. He joined his father in America in 1747, entered a mercantile house, and in 1754 became a member of a prosperous firm in which he later became partner. In the Revolution Morris sided with the colonists, but associated himself with the conservative group of Pennsylvania Whigs rather than with the more radical faction represented by Thomas Paine. He was vice-president of the Pennsylvania committee of safety (1775–76), and a member of the Continental Congress (1775–78). At first he disapproved of the Declaration of Independence, but he joined the other members in signing it on Aug. 22. He retired from Congress in 1778, and was at once sent to the legislature, serving in 1778–79 and in 1780–81. His greatest public service was the financing of the War of Independence. As chairman or member of various committees he practically controlled the financial operations of Congress from 1776 to 1778, and when the board system was superseded in 1781 by single-headed executive departments he was chosen superintendent of finance.

With the able co-operation of his assistant, Gouverneur Morris —who was in no way related to him—he filled this position with great efficiency during the trying years from 1781 to 1784. For the same period he was also agent of marine, and hence head of the Navy department. Through requisitions on the States and loans from the French, and in large measure through money advanced out of his own pocket or borrowed on his private credit, he furnished the means to transfer Washington's army from Dobbs Ferry to Yorktown (1781).

In 1781 he established in Philadelphia the Bank of North America, chartered first by Congress and later by Pennsylvania. A confusion of public and private accounts during the war, when his own credit surpassed that of the Government, gave rise to charges of dishonesty, of which he was acquitted by a vote of Congress. On the formation of the new Government he was offered, but declined, the secretaryship of the Treasury, and urged Hamilton's appointment in his stead. As U.S. senator, 1789–95, he supported the Federalist policies and gave Hamilton considerable assistance in carrying out his financial plans. After the war he gradually disposed of his mercantile and banking interests and engaged extensively in western land speculation. The slow development of this property, finally drove him into bankruptcy, and he was confined in a debtors' prison for more than three years (1798–1801). He died in Philadelphia on May 7, 1806.

BIBLIOGRAPHY.—The best biography is E. P. Oberholtzer's *Robert Morris, Patriot and Financier* (1903), based upon the Robert Morris papers in the Library of Congress; *see* also W. G. Sumner's *The Financier and the Finances of the American Revolution* (1891).

MORRIS, WILLIAM (1834–1896), English poet and artist, third child and eldest son of William Morris and Emma Shelton, was born at Elm house, Walthamstow, on March 24, 1834. His father came up to London in 1820, and entered the office of a firm of discount brokers in which he afterwards assumed a partnership. William was a delicate and studious child. When he was six the family moved to Woodford hall, where the boy's health improved. He was then sent to a school at Walthamstow, and, after his father's death, when the home at Woodford was broken up, to Marlborough. There he acquired a taste for architecture, fostered by the school library, and an attraction towards the Anglo-Catholic movement. In June 1852 he matriculated at Exeter college, Oxford, but he did not go into residence till Jan. 1853. Among his Oxford friends were Edward Burne-Jones and a little Birmingham group at Pembroke. They were known among themselves as the "brotherhood"; they read together theology, ecclesiastical history, mediaeval poetry, and, among moderns, Tennyson and Ruskin. They studied art, and fostered the study in the long vacations by tours among the English churches and the Continental cathedrals. Morris began at this time to write poetry.

Morris was entered (1856) as a pupil at the office of George Edmund Street, the architect; and on New Year's Day the first number of *The Oxford and Cambridge Magazine* appeared. The magazine existed for only a year. The chief immediate result was the friendship between Morris and Dante Gabriel Rossetti (*q.v.*), who became a contributor. In the summer of 1856 Street removed to London, and Morris accompanied him, working hard at architecture and painting. Rossetti persuaded him to devote himself exclusively to painting. Early in 1858 Morris published *The Defence of Guenevere,* which was almost unnoticed by contemporary criticism, but is now recognized as one of the pearls of Victorian poetry.

On April 26, 1859, Morris married Jane Burden, a beautiful Oxford girl, who had sat to him as a model, and settled temporarily at 41 Great Ormond Street, London. Meanwhile he set about building for himself at Upton a house which was to be the embodiment of all his principles of decorative art. Its furnishing had suggested a fresh activity; Morris now decided to begin decoration as a career. A small company was formed, consisting of D. G. Rossetti, Philip Webb, Burne-Jones, Madox Brown, Faulkner and Marshall, and in Jan. 1862 started business under the title of Morris, Marshall, Faulkner and Co., with offices at 8 Red Lion square. The firm undertook church decoration, carving, stained glass, metalwork, paper-hangings, chintzes and carpets. The business, after inevitable vicissitudes, flourished, but the "house beau-

tiful" at Upton proved to be unhealthily situated. Serious illness obliged the family to remove to town, and in Nov. 1865 they re-settled at 26 Queen square, Bloomsbury. Morris was now unceasingly busy, but he found time to write. In June 1867 he published *The Life and Death of Jason,* which was at once successful; and in April 1868 the first two parts of *The Earthly Paradise.* The rest of this wonderful storehouse of poetic romance appeared in two volumes in 1869 and 1870. In 1871, he took Kelmscott manor house, in the Upper Thames valley, in joint-tenancy with Rossetti, for use principally as a holiday home. In 1872 appeared *Love is Enough,* structurally the most elaborate of his poems; and in the autumn he began to translate the shorter Icelandic sagas, to which his enthusiasm had been directed by two inspiring journeys to Iceland. Business worries, however, interrupted him; the company had grown out of proportion with the existing division of profit and labour, and reconstruction was necessary. Long negotiations ensued, and in March 1875 the old firm was dissolved. Morris now became sole manager and proprietor.

Meanwhile in addition to his work upon the sagas, Morris had actually finished and (in 1875) published a version of the *Aeneid.* In 1876 appeared *Sigurd the Volsung,* a version full of heroic vigour, movement and vitality, but somewhat too lengthy and incoherent in design to preserve the epic interest intact to the British taste. This splendid burst of poetic activity had raised him to a place among the first poets of his time; and in 1877 he was offered the professorship of poetry at Oxford, which he declined. A fresh outlet for his energy was furnished by his foundation in 1877 of the Society for the Protection of Ancient Buildings, which sprang into being as a practical protest against a scheme for restoring and reviving Tewkesbury abbey.

At first Morris inclined, in politics, to the Radical section of the Liberal party, but in Jan. 1883 he joined the Democratic Federation, soon afterwards becoming treasurer of the party. On Dec. 30, 1884, he and others seceded from the Federation and formed the Socialist League, largely on the grounds that parliamentary action on which the leaders of the Federation tended to concentrate, was premature. Morris was appointed treasurer and editor of the monthly organ of the new League, the *Commonweal,* to which he later contributed his *Dream of John Ball* and *News from Nowhere.* The League started by repudiating State Socialism, and later became definitely opposed to parliamentary action. Morris lectured and spoke at meetings, and was several times arrested for obstruction in open-air meetings. But he was beginning to see that the time was not ripe for revolution. In 1890 the Anarchist section of the Socialist League became dominant, and Morris had to relinquish the editorship of the *Commonweal.* He still kept up with the Hammersmith Branch, which became independent, and met at Kelmscott House until its dissolution in 1892. But from this time on he took up a negative position. His *News from Nowhere,* published in book form in 1891, is a delightful and inspiring book, and a classic of the English movement, describing an England in which the socialist commonwealth has been realized.

Long before that time, however, Morris had returned to art and literature. When his business was enlarged in 1881 by the establishment of a tapestry industry at Merton, in Surrey, Morris found yet another means for expressing the mediaevalism that inspired all his work, whether on paper or at the loom—or indeed in political thought. In 1887 he published his translation of the *Odyssey.* He then added another to his multitudinous activities; he assumed a direct interest in typography. *The House of the Wolfings,* which was printed in 1889 at the Chiswick Press, was the first essay in this direction; and in the same year, in *The Roots of the Mountains,* he carried his theory a step further. Some 15 months later he added a private printing-press to his multifarious occupations, and started upon the first volume issued from the Kelmscott Press, his own *Glittering Plain.* For the last few years of his life this new interest remained the absorbing one.

His last piece of work, decidedly the crowning glory of his printing-press, was the *Kelmscott Chaucer,* which had taken nearly two years to print, and fully five to plan and mature. It was finished in June 1896. His vigour had been slowly declining for some time, and he sank gradually during the autumn, dying on Oct. 3, 1896. He was buried in Kelmscott churchyard.

Essentially the child of the Gothic revival, he had put an ineffaceable stamp on Victorian ornament and design, his place being that of a follower of Ruskin and Pugin, but with a greater practical influence than either. In house decoration of all kinds —furniture, wall-papers and hangings (which he preferred to paper), carpet-weaving, and the painting of glass and tiles, needlework, tapestry—he formed a school which was dominated by his protest against commercialism and his assertion of the necessity for natural decoration and pure colour, produced by hand work and inspired by a passion for beauty irrespective of cheapness or quickness of manufacture.

His friend Swinburne said that he was always more truly inspired by literature than by life. His socialism was tinged by a passionate enthusiasm for an inaccessible artistic ideal. Morris, indeed, was not primarily interested in men at all, but in objects. His poetry deals, it is true, with the human passions, but the emotion is always seen as in a picture; he is more concerned with the attitude of the group than with the realization of a character. But the spirit of beauty breathes in every line; a sense of music and of colour is everywhere abundant. Nor does the poet lack power and vigour when an adventurous story is told. Over all hangs the faint atmosphere of mediaevalism, of an England of green gardens and grey towers, of a London "small and white and clean," of chivalry and adventure in every brake. The critic has also to remember the historical value of Morris's literary influence, following upon the prim domesticities of early Victorian verse, and breaking in upon Tennyson's least happy phase of natural homeliness.

Sparling, *The Kelmscott Press and William Morris* (1924); G. Fritzsche, *William Morris' Sozialismus und anarchistischer Kommunismus* with bibliography (1927).

MORRIS-DANCE or **MORRICE-DANCE,** an old English dance, which is said by various authorities to have been introduced by John of Gaunt from Spain or borrowed from the French or Flemings. That it was a development of the morisco-dance or Spanish fandango is not invalidated by the fact that the morisco was for one person only, for, although latterly the morris-dance was represented by various characters, uniformity in this respect was not always observed. There are few references to it earlier than the reign of Henry VII., but it would appear that in the reign of Henry VIII. it was an almost essential part of the principal village festivities. In earlier times it was usually danced by five men and a boy dressed in a girl's habit, who was called Maid Marian. There were also two musicians; and, at least sometimes, one of the dancers, more gaily and richly dressed than the others, acted as "foreman of the morris." The garments of the dancers were ornamented with bells tuned to different notes so as to sound in harmony. Robin Hood, Friar Tuck and Little John were characters extraneous to the original dance, and were introduced when it came to be associated with the May-games. The morris-dance was abolished along with the May-games and other festivities by the Puritans, and, although revived at the Restoration, the pageant gradually degenerated in character and declined in importance. Maid Marian latterly was personated by a clown, who was called Malkin or Marykin. The interest of the subject has revived in recent years in connection with the new movements associated with folk-music generally. (*See* also DANCE; FOLK-DANCE.)

MORRIS MOTORS (1926), LTD., the organisation of Morris Motors (1926), Ltd., occupying works at Cowley, England, and with an output of nearly 100,000 cars a year, had its inception when, at the age of seventeen, after nine months' apprenticeship in the cycle trade, Sir William Morris Bt., decided to go into business on his own account.

When the light car movement began Mr. W. R. Morris (as he then was) rapidly grasped the type of car for which an eager

public was clamouring. Up to this time cars—English cars especially—had been heavy unwieldy vehicles, expensive to run.

The 1912 Morris-Oxford, the forerunner of all Morris cars of to-day, was a light, sturdily constructed car with a highly efficient engine, and economical to run.

In the large works at Cowley, the embryo car is seen in the form of two flat strips of steel which, passing underneath a huge press, costing no less than £10,000, emerge a few seconds later as side members. The cross members are added, all the holes drilled at a single operation and the chassis frame begins its journey upon the assembly line. The chassis grows, passing from one group of workmen to another as each component is added.

The works at Cowley, near Oxford, employ between 3,500 and 4,000 men and have a covered floor space of some $81\frac{1}{4}$ acres, where a wide range of cars is turned out, from the little Morris Minor to a luxury Six-Cylinder Saloon. (C. R. L.)

MORRISON, ARTHUR (1863–), English novelist, was born in Kent on Nov. 1, 1863. He was for a short time a clerk in the civil service, and in 1890 took to journalism. *Tales of Mean Streets* (1894) and *A Child of the Jago* (1896) contained admirable realistic descriptions of London life. He also wrote plays.

MORRISON, GEORGE ERNEST (1862–1920), British journalist and traveller, was born at Geelong, Australia, and educated at Melbourne University. From 1882 he travelled extensively in the South Sea Islands, where he studied the Kanaka labour question; in Australia, which he crossed on foot from the Gulf of Carpentaria to Melbourne; and in New Guinea. He took his M.D. degree in 1887 and after journeys to the United States and the West Indies he worked in his medical capacity in Spain, Morocco and Australia. In 1893 he abandoned medical work and set off on extensive travels in the Far East. He was special correspondent of *The Times* (London) in Siam (1895), and in Peking (1907–12). He visited every province and dependency in the Empire, with the exception of Tibet, and gained an intimate knowledge of men and affairs. In 1912 after the revolution he resigned his *Times* appointment and became political adviser to Yuan Shih-K'ai, president of the newly formed Chinese Republic. Dr. Morrison's published works include *An Australian in China* (1895). He died at Sidmouth, Devonshire, on May 30, 1920.

MORRISON, RICHARD JAMES (1795–1874), English astrologer, commonly known by his pseudonym "Zadkiel," was born on June 15, 1795. He served in the Royal Navy, but resigned with the rank of lieutenant in 1829. He then devoted himself to the study of astrology, and in 1831 issued *The Herald of Astrology,* subsequently known as *Zadkiel's Almanac.* In this annual pamphlet Morrison, over the signature "Zadkiel Tao-Sze," published predictions of the chief events of the coming year. He died on April 5, 1874.

MORRISON, ROBERT (1782–1834), the first Protestant missionary to China, was born of Scottish parents at Buller's Green, near Morpeth, on Jan. 5, 1782. After receiving an elementary education in Newcastle, he was apprenticed to a lastmaker, but his spare hours were given to theology, and in 1803 he was received into the Independent academy at Hoxton. The London Missionary Society sent him out to Canton in 1807. He became translator to the East India Company's factory there in 1809, and worked at a *Chinese Grammar* and a translation of the New Testament, both published in 1814. In 1817 he published *A View of China for Philological Purposes,* and his translation of the Old Testament (in which William Milne collaborated) was completed in the following year. He established (1820) an Anglo-Chinese college at Malacca for "the reciprocal cultivation of Chinese and European literature," and for the training of native Chinese evangelists who could proceed to the mainland and carry on Christian work with comparative immunity. In 1821 Morrison's *Chinese Dictionary* (6 vols.), was published by the East India Company. Leaving China at the close of 1823, Morrison spent two years in England, where he was elected a fellow of the Royal Society. Returning to China in 1826, he began to prepare a Chinese commentary on the Bible and other Christian literature. He died at Canton on Aug. 1, 1834. Morrison's establishment of a dispensary, manned by a native who had learned the main principles of European treatment, marks him out as the forerunner of modern medical missions.

His *Memoirs,* compiled by his widow, were published in 1839. *See* also R. Lovett, *History of the London Missionary Society,* vol. ii. ch. xix.; C. S. Horne, *The Story of the L. M. S.* ch. v.; Townsend, *Robert Morrison* (1888).

MORRISTOWN, a town of northern New Jersey, U.S.A., the county seat of Morris county; 30 m. W. of New York city, on the Whippany river and the Lackawanna railroad. Pop. (1920) 12,548 (19% foreign-born white and 7% negroes); 1930 Federal census 15,197. The town has a beautiful location, among wooded hills interspersed with lakes, at an altitude ranging between 400 and 700 ft. It is primarily a residential suburb, and has a number of large estates. At Morris Plains, 4 m. N., is a State hospital for the insane (1876). Morristown was founded (as West Hanover) in 1710 by Puritans, who were attracted by the deposits of iron ore. In 1740 the present name was officially adopted, in honour of Lewis Morris (1671–1746), then governor of New Jersey. Washington made Morristown his headquarters from January to May 1777, and again from Dec. 1779 to June 1780. The building in which he was is still standing and contains a fine collection of Washingtonian furniture. Behind the court-house is the site of Ft. Nonsense (now a public park), which he had his soldiers build largely to keep them occupied. Benedict Arnold was tried (Dec.–Jan. 1779–80) in the Dickerson tavern (still standing). The town was incorporated in 1865.

THE HEADQUARTERS OF GENERAL WASHINGTON IN MORRISTOWN DURING THE AMERICAN WAR OF INDEPENDENCE

MORRISTOWN, a town of eastern Tennessee, U.S.A., 42 m. N.E. of Knoxville, at an altitude of 1,351 ft.; the county seat of Hamblen county. It is on Federal highways 511 and 25E, and is served by the Southern railway. Pop. 5,875 in 1920 (83% native white); 7,305 in 1930 by the Federal census. It is in the fertile and beautiful valley of the Holston river, where poultry-raising, dairying and tobacco-growing are the leading industries. The city has creameries, a tobacco warehouse, storage facilities for 3,600,000 eggs, large chick hatcheries and broiler feeding-stations. Its manufacturing industries include eight woodworking plants, three textile factories and a variety of other establishments. A municipal hydro-electric plant on the river (4 m. N.) was completed in 1926. Morristown was founded in 1830 and incorporated in 1855.

MORROW, DWIGHT WHITNEY (1873–1931), American lawyer and diplomat, was born at Huntington, W.Va., on Jan. 11, 1873. He was educated at Amherst (A.B., 1895) and Columbia (LL.B., 1899), and in 1899 entered the employ of the law firm of Simpson, Thacher and Bartlett. In 1905 he became a member of the firm and soon won a reputation in the organizing and financing of corporations. His many services brought him to the attention of J. P. Morgan and Co., in which firm he became a partner in 1914. His position with this firm during the World War period and after, when there were financial matters of great national and international import under negotiation, gave him wide experience and high standing. He was appointed by President Wilson adviser to the Allied Maritime Transport Council in 1918, and his work in connection with military shipping won him the Distinguished Service Medal in 1919. He was retained by Gen. Pershing for a time at Chaumont as his chief civil aid. In 1925 he was appointed chairman of the president's aircraft board. He was also active in charitable work and prison reform, his report as chairman of the Prison Inquiry Committee of New Jersey in 1917 resulting in a radical revision of penal legislation in that State. In Sept. 1927 he was appointed by President Coolidge ambassador extraordinary and plenipotentiary to Mexico. His friendly spirit and tactful negotiations resulted almost immediately in better relations between the two countries and in the settlement

of controversies over oil properties. He was retained in his position by President Hoover. He was one of the American delegates to, and played an influential part in, the Conference which resulted in the London Naval Treaty of 1930.

MORSE, SAMUEL FINLEY BREESE (1791–1872), American artist and inventor, was born at Charlestown (Mass.) on April 27, 1791. In 1810 he graduated at Yale college, where under the instruction of Jeremiah Day and Benjamin Silliman he received the first impulse towards electrical studies. In 1811 Morse, whose tastes during his early years led him more strongly towards art than towards science, became the pupil of Washington Allston and accompanied his instructor to England. In 1825 he was one of the founders of the National Academy of Design, and was its first president (1826–45). The year 1827 marks the revival of Morse's interest in electricity. But he was still devoted to art, and in 1829 he again went to Europe to study the old masters.

The year of his return, 1832, may be said to close the period of his artistic and to open that of his scientific life. He completed rough drafts of the necessary apparatus, upon which the modern telegraph substantially is modelled. During the 12 years that followed Morse was engaged in perfecting his invention and securing for it a proper presentation to the public. He made his own models, moulds, and castings. It was not until 1836 that he completed an apparatus that would work, and finally, on Sept. 2, 1837, the instrument was exhibited at the university of the City of New York with such satisfactory results as to interest Messrs. Vail, iron and brass workers in New Jersey, who thenceforth became associated with Morse in his undertaking. Morse's petition for a patent was soon followed by a petition to Congress for an appropriation to defray the expense of subjecting the telegraph to actual experiment to demonstrate its value.

Congress, however, adjourned without making the appropriation, and Morse sailed for Europe to take out patents there. In England his application was refused, and, while he obtained a patent in France, it was subsequently appropriated by the French government without compensation to himself. His negotiations with Russia proved futile, and after a year's absence he returned to New York. In 1843 Congress passed the appropriation, steps were taken to construct a telegraph from Baltimore to Washington, and on May 24, 1844 it was used for the first time. In 1847 Morse was compelled to defend his invention in the courts, and successfully vindicated his claim to be called the original inventor of the electro-magnetic recording telegraph.

FIRST TELEGRAPH-RECEIVING APPARATUS INVENTED BY SAMUEL MORSE

In 1858 the representatives of Austria, Belgium, France, the Netherlands, Piedmont, Russia, the Holy See, Sweden, Tuscany, and Turkey made a monetary appropriation in recognition of the use of his instruments in those countries. He introduced into America Daguerre's process of photography, patented a marble cutting machine in 1823, and in 1842 made experiments with telegraphy by a submarine cable. He died on April 2, 1872 at New York. (*See* TELEGRAPH.)

MORSE CODE: *see* TELEGRAPH.

MORSHANSK, a town of Russia in the province of Tambov, in 53° 28′ N., 41° 45′ E., on the Tsna river. It is a grain collecting centre and has an elevator, and has grown since the railway reached it. There are manufactures of glass, cloth, makhorka tobacco and sauce. Pop. (1926) 27,758. The village was founded in the 17th century.

MORTALITY STATISTICS: *see* DEATH RATE.

MORTAR: *see* BRICKWORK, MORTAR IN BUILDING and ORDNANCE.

MORTARA, EDGAR, an Italian Jew, of a Bologna family, whose abduction in early childhood (1858) by the Inquisition occupied for several years the attention of European diplomacy. When five years of age he fell ill. His nurse, a Catholic, arranged with her priest for his baptism in that faith, unknown to his parents, on June 24, 1858. She had tried to convert his elder brother in a similar way, but failed. This time everything was concerted in advance with the ecclesiastical authorities, and immediately after the baptism both child and nurse disappeared. The story became known, and protest was aroused in nearly every European country. Pius IX. maintained that the question at issue was a spiritual one, outside his temporal jurisdiction, and would not take any action, meanwhile indicating the direction of his sympathies by making Mortara his ward. In 1861 the Mortara family induced the Italian Government to demand the prosecution of the nurse, who had meanwhile entered a nunnery, but subsequently, on the threat of intervention by Prussia, they withdraw their plaint. After the capture of Rome by the Italian troops in 1870 Edgar Mortara had the opportunity of reverting to Judaism, but he refused to do so, and became an Augustinian.

MORTARA, town, Lombardy, Italy, province of Pavia, 354 ft. above sea-level, a railway junction situated between the Ticino and the Po, 32 m. by rail southwest of Milan. Pop. (1921), 8,167 (town); 9,740 (commune). It is the capital of the Lomellina district. Here the Austrians defeated the Piedmontese in 1849.

MORTAR IN BUILDING. This consists of granular and siliceous material, such as sand, crushed brick, or stone, chippings, or crushed clinker with a cementitious material, such as lime or cement, mixed and reduced to a plastic state with water. The purpose of mortar is to bed uniformly and to unite blocks of building material in order to provide continuous contact of surfaces for the transmission of loads and stresses, and also to render the joints weatherproof.

Lime mortar is in common use for buildings such as dwellings and for industrial structures of moderate height, but cement mortar is much better adapted for the transmission of great stresses and, therefore, more suitable for use in high buildings, foundations, piers, etc. Cement mortar is also used for pointing or filling of external joints in all buildings where weathertight beds and vertical joints are required. Lime mortar is much weaker than most building materials; cement mortar more nearly approaches the strength of bricks and stones and enables these to withstand higher stresses than if bedded in lime mortar. Where the latter is used for bedding building blocks it should be of the character known as "hydraulic," especially for work at or below the ground level. Pure or fat limes are most suitable for the process of internal wall plastering. Grey stone lime which has slight "hydraulic" properties makes a good mortar for general work above ground.

Mixing.—Lime mortar may be mixed by hand or by machinery. Well slaked lime must be thoroughly mixed and incorporated with fine granular material, using sufficient water to make it plastic for manipulation with the trowel. Where a mill is used, stone chippings, furnace clinker or other substitute for sand may first be ground under the heavy rollers, in water, to a fineness approaching that of sand; the lime may then be added and the mixing accomplished by a similar operation which must not be prolonged otherwise there is a danger of reducing the particles to a much finer state which results in a fattier mass and reduces the probability of setting in the interior of the mass. Mortar made from hydraulic lime or cement or mortar gauged with cement must be mixed in quantities sufficient only for immediate use; cement cannot usefully be reworked after its initial set has begun because its setting properties are reduced, and the resulting mortar is weak and unsound.

Slaking.—This is a most important operation in the process of making mortar. There are three methods of slaking lump lime —the first by immersion, the second by sprinkling with water, and the third by exposing the lime to the atmosphere and leaving it to absorb moisture. Different qualities of lime require varying amounts of water, but the average quantity is about a gallon and a half to every bushel of lime. It should all be added at one time

and the mass then left to slake undisturbed. Hot limes are often used for mortar. These are unsuitable for plastering unless slaked for a long period. When mortars composed of these limes are used immediately after mixing, slaking must continue for a long time absorbing the moisture necessary for setting, making the work liable to serious damage by expansion of the slaking particles and often causing the mortar to crumble to dust in the joints of the brickwork. There was an old Roman enactment which set forth that lime should be slaked for three years before using and in the south of Europe it is still the custom to slake lime the season before it is used.

The results of many careful tests and experiments serve to show that the hardening of mortar is due to several causes acting collectively. With ordinary lime mortars the chief causes of hardening are the absorption of carbonic acid from the air and the combination of part of the water with the lime, which unites with some of the silica of which the sand is composed and forms silicate of lime. The initial setting is due to the evaporation of the excess of water and to the production of minute crystals of hydrate of lime which slowly combine with carbon dioxide from the air. With mortar of rich lime an outer crust is thus formed on the exposed parts which prevents ready access of air to the interior and confines the setting of the interior of the mass to a very slow and often incomplete formation of particles of silicate of lime.

The setting and hardening of hydraulic limes and cements are due mainly to crystallization brought about by the action of water on the silicate of lime. As a consequence we find that good hydraulic limes and cements have the valuable property of setting hard while immersed in water and in many cases growing increasingly hard with the lapse of time.

Extra Constituents. *Magnesia.*—Opinions differ on the question of the suitability for building purposes of limes or cements which contain an appreciable proportion of magnesia, many experts holding the view that the expansion which often occurs in floors and other works of concrete from one to four years after laying may be justly attributed to the presence of this substance. For mortars, however, it may be assumed that the presence of magnesia is not detrimental to the value of the matrix, but on the contrary may be a source of strength, for experiments show that it reduces the energy of slaking and increases that of the setting processes. Cements containing magnesia are pronounced both by Vicat and Chatoney to resist the dissolving action of sea-water better than those in which no magnesia is present and it is pretty well established by experience that cements derived from argillo-magnesian limestone furnish a durable cement for construction in the sea. Recent specifications for Portland cement provide that magnesia contents shall not exceed 2% of the whole and modern writers express the view that magnesia in excess of 4% is dangerous as it reduces the tensile strength of the cement under normal conditions and makes mortar or concrete unsound. (*See* CEMENT.) It is a good plan, where the question of cost precludes the use of mortar made entirely of cement, to add to lime mortar mixed in the usual proportions a small quantity of Portland cement. This is termed "gauged" lime mortar. By this addition the strength is greatly increased at little extra cost.

Adhesive Strengths of Lime and Cement Mortars

	Proportions	Approximate stress
White chalk, lime and sand . .	1 to 3	4¾ lb. per sq.in.
Barrow lias, " " " . .	1 " 3	9 " " " "
" " " " " . .	1 " 4	6¾ " " " "
Portland cement	1 " 4	23 " " " "
" "	1 " 6	15½ " " " "

Adhesion of Mortar.—The above table shows the force required to tear apart common stock bricks bedded in mortar, mixed in proportions commonly used, and left to set and harden for four weeks. These results indicate that the adhesive strength of mortar varies with the proportion of sand used, the resistance decreasing as the proportion of sand is increased. The primary cause of the premature decay which sometimes takes place in mortars and like material is due to the presence of impurities or of decayed vegetable and animal matter in the sand, though the lime or cement itself may be defective. It is therefore of great importance to use a perfectly clean sand for the aggregate, and to select a lime or cement of good quality for the matrix, care being taken that no foreign matters detrimental to the mortar be introduced during the processes of preparation.

Salt.—In some German experiments, cubes of stone were joined together with cement mixed with waters of different character, ranging from pure rain-water to water containing from 2 to 8% of salt. Before the cement was set the blocks were exposed in air at a temperature varying from 20° F to freezing-point, after which they were kept for seven days in a warm room. The samples were then examined with these results: The cement mixed with pure water was crumbled, having lost all its tenacity. The cement made with water containing 2% of salt was in a better condition, while that containing 8% of salt had not suffered from its exposure to frost. The use of salt causes efflorescence on the face of the work, and should therefore not be used where this would be undesirable; nor should salt be employed for work that is to be subsequently painted. The mortar for the brick facing of the Forth Bridge below water was composed of one part of Portland cement and one part of sand mixed with salt water in a mill. Briquettes made from this compound withstood a tensile stress of an average of 365 lb. per square inch when a week old, and of 510 lb. at five weeks after mixing. Salt has no serious effect upon the strength of a mortar, although it definitely retards the setting process.

Sugar.—Cement mixed with a percentage of sugar (usually 2% and under) has been used with varying success. In India sugar is a frequent ingredient in mortar, probably because it has the effect of preventing too rapid setting; it also retards the drying of the material. The sugar must be dissolved in the water used for gauging, as the results obtained when the sugar is mixed with the other ingredients in a dry state are not good. The addition of sugar to water enables it to take up very much more lime than pure water. It is supposed by many writers who have studied the methods of the ancients that old Roman mortars contained strong ale, wort or other saccharine matter, and it is probable that the use of sugar with lime passed from India to Egypt and Rome.

Limes and Cements for Mortar.—The varieties of lime and cement chiefly used for mortar in the British Isles are set forth below:—

Pure or fat limes should not be used for mortar. Grey stone lime, feebly hydraulic, makes a good mortar, but should not be employed for work below ground or in other damp situations. It is obtained in many places including Dorking, Halling, Lewes and Merstham. It is used in the proportion of one part to two or three parts of sand. An analysis of the lime from Castle Bytham gave the following composition:—

Silica	14·00
Iron oxide and alumina	4·25
Lime	77·00
Magnesia	1·25
Carbon dioxide	0·90
Water and loss	2·60
	100·00

Blue lias lime is eminently hydraulic and should be used in good class work. Its use is a necessity for foundations and work in damp situations where Portland cement is not employed. It is used in the proportions of one part to one or two parts of sand. The best-known varieties are obtained from Watchet and Keynsham in Somersetshire, Barrow-on-Soar in Leicestershire, Rugby in Warwickshire, Lyme Regis in Dorsetshire, Aberthan in Glamorganshire, and other places. A typical lias lime showed on analysis the following composition:—

Silica	17·53
Iron oxide	2·87
Alumina	6·83
Lime	65·84
Magnesia	1·00
Sulphuric anhydride	1·36
Water and carbon dioxide	3·85
Insoluble matter and loss	0·72
	100·00

Portland cement is the best matrix known, since it is the most powerful and the most durable. It is used for mortar wherever great strength, hard-wearing properties, and resistance to damp are required. It should weigh 90 lb. per cu.ft. and be ground fine enough to pass through a standard sieve having 32,400 meshes to the square inch and leave not more than 10% residue; not more than 1% residue should remain on a standard sieve having 7,700 meshes per sq. inch. Test briquettes after setting under water for seven days should stand a tensile stress of 400 lb. on a square inch. It is used in the proportions of one part of cement to from one to five parts of sand.

Portland cement of a similar general character to the English cement is made on the continent of Europe and in America. The first American Portland cement was manufactured in 1874 by Mr. David O. Saylor.

The chief works of reference on this subiect are G. R. Burnell, *Limes, Cements, Mortars;* Rivington, *Notes on Building Construction,* Vol. III.; F. W. Taylor and S. E. Thompson, *A Treatise on Concrete, Plain and Reinforced.*

MORTGAGE, the securing "money or money's worth" by making it a charge upon property, real or personal, so that if the debt be not paid by a time agreed upon by the parties, the creditor may foreclose or sell the property and pay himself out of the proceeds. In English law this is done by an actual or executory conveyance of the property to the creditor, subject only to its being defeated if the debt should be paid at the time fixed. Under the altered system initiated by the Law of Property Act, 1925, mortgages are charged without conveyance of the property to the mortgagee. (*See* HYPOTHEC.)

The mortgage of English law is the result of two distinct influences. Its origin and form belong to the common law; the restrictions by which it is made to serve the purpose of a security only, and nothing more, belong to the courts of equity. In the eye of the common law the mortgagee was the owner of the estate conveyed in the mortgage; in equity the mortgagor remains the real owner, and the mortgagee is merely an encumbrancer. At law, after failure of payment, the land belonged absolutely to the mortgagee, while in the meantime, before payment, the legal estate was considered to be vested in him, subject only to being defeated by payment at the proper time. The court of chancery first interfered in the reign of James I. to decree a redemption after forfeiture, and a case in the reign of Charles I. decides that payment after forfeiture has the same effect as payment before. The right of the mortgagor to redeem his estate after it has been forfeited, according to the terms of the deed, is called his *equity of redemption.* No agreement between the parties was suffered to oust the jurisdiction of the court, or to deprive the debtor of his equity of redemption. And this equity, at first regarded as a mere right of the debtor, became established in course of time as an estate in land which descended to the heirs of the mortgagor. In spite of the terms of the mortgage, the owner of the land is still the owner. It may be a question whether a given deed is a conveyance or a mortgage, and the court, in deciding, will look at all the circumstances of the case, and will treat it as a mortgage when it was the real intention of the parties that it should operate as a security only.

A mortgagee may, however, on default of payment file a bill of foreclosure requiring the mortgagor to pay the amount of the debt with interests or costs by an appointed day, or submit to be deprived of his equity of redemption. The effect of failure to pay by the time appointed would be to make the mortgagee absolute owner of the estate; but the court in any foreclosure suit may, at the request of either side, order a sale instead of a foreclosure. The mortgagee is entitled to retain out of the proceeds of the sale the amount of his principal, interest and costs, the surplus belonging to the mortgagor.

An *equitable* mortgage is constituted simply by the deposit of title-deeds in security for money advanced. Any subsequent legal mortgagee, having notice of the deposit, will be postponed to the equitable mortgagee, and when the legal mortgagee has not inquired as to the title-deeds the court will impute to him such knowledge as he would have acquired if he had made inquiry. A Welsh mortgage is one in which an estate is conveyed to a creditor, who takes the rents and profits in lieu of interest and without account, the estate being redeemable at any time on payment of the principal. Any form of property, with few exceptions, may be mortgaged.

United States.—In America the common law mortgage was adopted in many States with such incidents as the English law had attached to it. Equity courts intervened to prevent strict foreclosure or the forfeiture of the equity of redemption upon non-payment of the debt, insisting that foreclosure should be only made by judicial sale. Many States, however, permit the mortgagee to reserve a power of sale in the deed, which he may exercise without the intervention of the court. In about one-third of the American States the common law mortgage no longer exists, a mortgage having the effect of giving the mortgagee a legal lien upon the property, the mortgagor still retaining title. The practical differences between this and the common law mortgage are not great. Chattel mortgages are also common in the United States, recording of such mortgages being required by most States in order that the mortgagee's rights shall prevail against innocent purchasers of the chattel from the mortgagor.

MORTIER, EDOUARD ADOLPHE CASIMIR JOSEPH, DUKE OF TREVISO (1768–1835), marshal of France, was born at Cateau Cambrésis on Feb. 13, 1768, and entered the army as a sub-lieutenant in 1791. He served in the campaigns of 1792 and 1793 on the north-eastern frontier and in the Netherlands, and subsequently on the Meuse and the Rhine. In the war against his second coalition in 1799 he was promoted successively general of brigade and general of division. Following his conduct of the French occupation of Hanover he was created marshal in 1804. He commanded a corps of the *grande armée* in the Ulm campaign, distinguishing himself by his brilliant action of Dürrenstein; in 1806 he was again in Hanover and north-western Germany, and in 1807 he served with the *grande armée* in the Friedland campaign. In 1808 he was created duke of Treviso, and he commanded an army corps in Napoleon's campaign for the recapture of Madrid. He won the victory of Ocaña in November 1809. In 1812 and 1813 he commanded the Young Guard, and in the "defensive" campaign of 1814 he rendered brilliant services in command of rearguards and covering detachments. In 1815, after the flight of Louis XVIII., he rejoined Napoleon, but at the opening of the Waterloo campaign he fell ill. After the second restoration he was for a time in disgrace, but in 1819 he was readmitted to the Chamber of Peers. In 1830–1831 he was ambassador of France at St. Petersburg, and in 1834–1835 minister of war and president of the council of ministers. In 1835, while accompanying Louis Philippe to a review, the marshal with eleven other persons was killed by the bomb aimed at the king by Fieschi (July 28, 1835).

MORTIFICATION or **GANGRENE.** A medical term signifying death in mass of some part of the body (*e.g.*, a portion of a limb or lung or a strangulated portion of gut) with the subsequent changes undergone by the part. Gangrene is always the result of interference with blood supply, and the appearances differ according as obstruction concerns the arterial supply or the venous return. If the artery is occluded and blood cannot reach the part by collateral circulation the part dies and evaporation from the surface causes it to dry and shrivel (*dry gangrene* or *mummification*). If the veins are occluded the part becomes oede-

matous and undergoes putrefaction (*moist gangrene*). Which of the two varieties will occur depends upon circumstances. If the arteries are diseased as in arteriosclerosis it is dry gangrene that occurs; if the part is inflamed and infiltrated with exudation and blood, as in some cases of comminuted fracture of bone, moist gangrene occurs. In such diseases as diabetes and chronic renal disease, where the nutrition of the tissues is already impaired, or in cardiac conditions in which the effective power of the heart as a pump is impaired, gangrene may arise after minor injuries or even spontaneously. If the nutritive condition of the patient is sufficiently good the dead material is separated from the living in time and cast off by a process of inflammation. This process may often be replaced by surgical amputation. The blackness of a gangrenous part is due to the formation of sulphide of iron from the broken-down red blood corpuscles. Frost bite (*q.v.*) is in reality only a specialized variety of gangrene.

MORTIMER (*Family*). The Mortimers of Wigmore, earls of March and Ulster, were akin to the dukes of Normandy. Their ancestor Hugh, bishop of Coutances in 990, had three sons, the eldest being Ralph, father of William of Warenne, earl of Surrey, and the second Roger of Mortemer-en-Brai. In the battle at his own village, Roger was a leader of the force which defeated the French, but, releasing an enemy of his duke, he was punished by the loss of his castle. The Mortimers' chief seat in Normandy became St. Victor-en-Caux. Roger's son, Ralph, who became heir to his father's lands, followed his kinsman, William Fitz-Osbern, the earl of Hereford, to the marches of Wales, and the Domesday book for Hereford and Shropshire marks the growth of the Mortimer power in those countries. After the rising of the 2nd earl of Hereford, he was enriched by many of the earl's forfeited estates, among them the castle town of Wigmore, which became the chief seat of Mortimer and Cleobury, thereafter called Cleobury Mortimer. His Domesday lands lie in eleven counties, especially in North Hereford and South Shropshire. Ralph rose in 1188 with the other barons of the March, but was reconciled to William II., whom he afterwards supported in Normandy. In 1104 he was a partisan of Henry I., and must have died soon afterwards.

Ralph de Mortimer, the 5th baron of Wigmore (d. 1246), married the daughter of Llewelyn, prince of Wales, and by her was father of Roger, whose bride, Maude de Breuse, brought in a third of the honour of Breuse of Brecknock, and a share of the honour of the earls marshal. So came the lordship of Radnor with other lands, and the history of the Mortimers ceases to be a provincial record. The last-named Roger supported Henry III. in his struggle with the barons. In 1282, he was succeeded by Edmund, the eldest surviving son (d. 1304), Roger, a third son, founding the line of Mortimer of Chirk.

By Margaret de Fiennes, a kinswoman of Queen Eleanor of Castile, Edmund Mortimer was father of Roger (b. 1287), whose great inheritance was increased on his marriage with Joan, daughter and heir of Peter de Geneville, her grandmother being a coheir of Lacy. The whole of the Geneville lands, with the half of the Lacy fief in England and Ireland, came through her to the Mortimers, who now added the castle town of Ludlow and half Meath to their estates. During the war with the Despensers, the force of the Mortimers was cast against the king but after Bridgnorth Castle had been taken, Edmund's son, Roger, was imprisoned for two years before he made his famous escape to France. At the court of Charles IV. the exile met Isabel, the queen of England, and early in 1326 the scandal of her close friendship with the lord of Wigmore had reached England. When the queen landed at an English port in September, Mortimer was with her, and he followed the flight of the king to Wales. He was among the judges of the elder Despenser at Bristol, and of the younger, his chief enemy, at Hereford. After parliament deposed Edward II. and made the young Edward king in his stead, Roger, as the queen's paramour, ruled England. Enriched by the lands of the Despensers, and by those of the earl of Arundel, beheaded at his command, Mortimer, who was created earl of March in 1328, never ceased to add to his possessions. The young king, however, worked secretly for his fall. Montague's men-at-arms entered Nottingham Castle by night, and joining the king, seized the favourite in his chamber next the queen's. Mortimer was hurried to London and condemned by the peers; his death followed suddenly.

Roger, who fought at Crécy in "the king's battle," was restored to a great part of the forfeited inheritance. A founder of the Order of the Garter, he was summoned as a baron and obtained a reversal of his grandfather's attainder. In 1355 he was summoned as earl of March. But following his king in the invasion of Burgundy, he died suddenly at Rouvray in 1360.

His only son, Edmund, succeeded him as 3rd earl of March (1351–1381). His marriage with Philippa, daughter of Lionel of Antwerp, duke of Clarence, by Elizabeth de Burgh, the heir of Ulster, added the earldom of Ulster to his style, and brought his issue into the direct succession of the Crown. Elizabeth, their eldest child, became the wife of the famous Harry Percy, called Hotspur. Their second child was Roger, who succeeded to his father's two earldoms as a boy of seven, and was at once appointed lieutenant of Ireland. He married Eleanor Holand, niece of King Richard, and in the parliament of 1385 the king named him heir-presumptive to the throne. In 1398 he was killed at Kells in one of his petty wars with the Leinster men, and once more a child succeeded to the earldoms. Edmund, 5th earl of March, was, for the king's party, the heir-presumptive of the kingdom, but by the coming to power of the Lancastrian party in 1399, Henry IV.'s first parliament recognized Henry's son as heir-apparent. March served Henry V. in his French wars, and on the accession of Henry VI. the earl was appointed to the lieutenancy of Ireland which had been held by his father and grandfather. He died suddenly of the plague in Ireland on Jan. 19, 1425. With him the illustrious house of the Mortimers, earls of March and Ulster, became extinct. Their lands and earldoms passed to Richard, duke of York, son of Richard of Cambridge, by the last earl's sister.

MORTISE or **MORTICE,** a term for a socket or cavity cut in a piece of wood, or other material, into which a corresponding projecting end, a "tenon," fits, the two when fitted together forming a "mortise-joint," for fastening two beams or other pieces of timber together. When locks are made to be imbedded in a socket cut in the thickness of a door they are termed mortise-locks.

MORTLAKE, a village in Surrey, England, on the Thames, 6½ m. W. of London. Pop. of parish, in urban district of Barnes, (1921) 19,502. The Oxford and Cambridge boat-race finishes here. The village appears in Domesday, and the manor belonged to the Archbishops of Canterbury until it passed by exchange to Henry VIII.

MORTMAIN, the state or condition of lands or tenements when held by a corporation in perpetual or inalienable tenure. Alienation in mortmain having the effect of depriving the lord of the incidents of seignory, many English statutes were passed directed against such alienation. Later statutes were based rather on economic and social grounds. The earliest is that of Henry III. 36; others being 7 Edward I. 13 (De Viris Religiosis); 13 Edward I. 32; 15 Richard II. 5; and 23 Henry VIII. 10. The present law is regulated by the Mortmain and Charitable Uses Act 1888, as amended by the Act of 1891.

A few British colonies, such as Ontario, have passed similar legislation.

In the United States mortmain acts have been passed in some jurisdictions restricting the right of corporations to hold land and also their power to make devises or conveyances or to receive land by devise.

MORTON, JAMES DOUGLAS, 4th Earl of (*c.* 1525–1581), Scottish statesman, was the son of Sir George Douglas of Pittendriech, and before 1543 married Elizabeth (d. 1574), daughter of the 3rd earl of Morton, to whose titles and estates he succeeded in 1553. Ten years later he became lord high

chancellor of Scotland. He headed the armed force which took possession of Holyrood palace in 1566 to effect the assassination of Rizzio, and it was to his house that the leading conspirators adjourned while a messenger was sent to obtain Mary's signature to the "bond of security." The queen, before complying with the request, escaped to Dunbar, and Morton and the others fled to England. Having been pardoned, Morton returned to Scotland early in 1567. He led the army which defeated the queen's forces at Langside in 1568, and was the most valued counsellor of the earl of Murray during his regency. In Oct. 1572, he himself was elected regent. He effected a pacification with Huntley, the Hamiltons, and the Catholic nobles who supported Mary, and took by arms the castle of Edinburgh.

There were, however, undercurrents which combined to procure Morton's fall. The Presbyterian clergy were alienated by his leaning to Episcopacy, and all parties in the divided Church by his seizure of its estates. When the powerful earl of Argyll and Atholl, a Stuart and Roman Catholic, united with Alexander Erskine, governor of Stirling, and others, Morton offered to resign. He surrendered the castle of Edinburgh, the palace of Holyrood, and the royal treasures, and retired to Lochleven. But his ambition could not deny itself another stroke for power. Aided by the young earl of Mar, he got possession of Stirling Castle and the person of the young king. A nominal reconciliation was effected, and a parliament at Stirling introduced a new government. Morton, who secured an indemnity, was president of the council, but Atholl remained a privy councillor in an enlarged council with the representatives of both parties. In 1580 Morton was condemned by an assize for having taken part in the murder of Darnley, and the verdict was justified by his confession that Bothwell had revealed to him the design, although he denied participation in its execution. He was executed on June 2, 1581.

MORTON, JOHN (*c.* 1420–1500), archbishop of Canterbury, cardinal and statesman, was born either at Bere Regis or Milborne St. Andrew. Educated at Balliol college, Oxford, he graduated in law, and followed that profession in the ecclesiastical courts in London. He is said (*Dict. Nat. Biog.*) to have been "at once admitted to the privy council"; but probably this is a mistake for the ordinary council, of which Morton might well have been made a member when he was appointed master in chancery and chancellor of the duchy of Cornwall. He received a good deal of ecclesiastical preferment from the Lancastrian party, was present, if he did not fight on the losing side, at the battle of Towton in 1461, and was subsequently attainted by the victorious Yorkists. He lived with the exiled court of Margaret of Anjou at Bar until 1470, and took an active part in the diplomacy which led to the coalition of Warwick and Clarence with the Lancastrians and Louis XI., and indirectly to Edward IV.'s expulsion from the throne. Morton landed with Warwick at Dartmouth in September 1470, but the battle of Tewkesbury shattered the Lancastrian hopes, and Morton made his peace with Edward IV.

In 1473 Morton was made master of the rolls; he was sent on a mission to Hungary in 1474, and was one of the negotiators of the Treaty of Picquigny in 1475. In 1479 he was elected bishop of Ely. He was one of the executors of Edward IV.'s will in 1483, but was arrested after the accession of Richard III. He escaped from Brecknock castle to Flanders, and worked in the interests of the earl of Richmond. When Richmond secured the crown as Henry VII., Morton became his principal adviser. He became archbishop of Canterbury in 1486 and lord chancellor in 1487. In the year 1493 Morton was created a cardinal, and in 1495 was elected chancellor of the university of Oxford. He encouraged learning to the extent of admitting Sir Thomas More into his household, and writing a Latin history of Richard III., which More translated into English. He died at Knole on Oct. 12, 1500, and was buried in Canterbury cathedral.

Besides the authorities cited in the *Dict. Nat. Biogr. see* the calendar of Patent Rolls, 1461–85, *passim;* W. Busch, *England under the Tudors* (1892); J. Gairdner, *Henry VII.* (1889) and *Lollardy and the Reformation* (1908), and *Political History of England,* vols. iv. and v. (Longmans).

MORTON, JOHN MADDISON (1811–1891), English playwright, the son of Thomas Morton (1764?–1838), also a playwright, was born at Pangbourne, on Jan. 3, 1811. He was the author of the famous farce *Box and Cox* (1847) and other pieces. He became a Charterhouse pensioner, dying on Dec. 19, 1891.

MORTON, LEVI PARSONS (1824–1920), American banker and politician, was born in Shoreham, Vt., on May 16, 1824. He was in business at Hanover, N.H., in 1843–49 and in Boston in 1849–54. He then became a partner in a New York dry-goods house. He established in 1863 the banking house of L. P. Morton and Company (dissolved 1899), with a London branch which had Sir John Rose (1820–88) as its principal member. The American firm assisted in funding the national debt at the time of the resumption of specie payments, and the London house were fiscal agents of the United States Government in 1873–84, and as such received the $15,500,000 awarded by the Geneva Arbitration Court in settlement of the "Alabama Claims" against Great Britain. He was a Republican representative in Congress in 1879–81, United States minister to France in 1881–85, vice-president of the United States in 1889–93, and in 1895–96 was governor of New York. He died in Rhinebeck, N.Y., on May 16, 1920.

See R. M. McElroy, *Life of Levi Parsons Morton* (1929).

MORTON, OLIVER PERRY (1823–1877), American political leader, "war governor" of Indiana, was born in Salisbury, Ind., on August 4, 1823. After studying for two years (1843–45) at Miami university, he practised law at Centerville, Ind., and in 1852 became circuit judge. In Feb. 1856 he was a member of the Pittsburgh convention which led to the organization of the national Republican party, and in the same year he was a candidate for governor of Indiana but was defeated. He was elected lieutenant-governor in 1860, and when Henry S. Lane, the governor, resigned, on January 16, 1861, Morton became governor. In 1864 he was re-elected. In meeting all the extraordinary demands resulting from the Civil War he displayed great energy and resourcefulness, and was active in thwarting the schemes of the secessionists in the neighbouring State of Kentucky, and of the secret societies of Southern sympathizers and other opponents of the war in Indiana. In 1863 a hostile legislature sought to deprive him of all control over the militia, and, failing in this, adjourned without making the appropriations necessary for carrying on the State government. In this predicament Morton appealed for financial aid to private individuals, bankers, the counties, and even the Federal government. The response was so prompt that he was able to conduct affairs practically single-handed until 1865, when a legislature more favourable to his policies assembled. Morton resigned as governor in Jan. 1867 to accept a seat in the U.S. Senate, in which he served during the rest of his life. He was recognized as one of the leaders of the Radical wing of his party, voting in favour of Johnson's impeachment, and being especially active on behalf of negro suffrage. He was a prominent but unsuccessful candidate for the Republican nomination for the presidency in 1876. He died at Indianapolis on Nov. 1, 1877.

See William D. Foulke, *Life of Oliver P. Morton* (Indianapolis, 1899).

MORTON, THOMAS (*c.* 1590–1646), usually called Thomas Morton of Merrymount, English adventurer in America, was a lawyer of Clifford's Inn, London, and seems to have practised in the west of England. He spent three months in America in 1622; returned in 1625, and settled at Mount Wollaston, in what is now Quincy, Massachusetts; and in 1626, when most of the settlers removed to Virginia, he assumed command of the settlement, and renamed it Merrymount. He came into conflict with the Puritan settlers, by setting up a maypole and also, it should be added, selling rum and arms to the Indians. He was banished to England, but returned in 1629, when he was arrested on trivial charges by the Massachusetts authorities, and was confined in the stocks. Later his house was burned and he was sent to England, where he spent a term in the Essex gaol. After his release he wrote his *New English Canaan* (1637), in which he heaps ridicule upon the New England colonists. In 1643 Morton returned to America. He was imprisoned in Boston in the following year, was brought to trial, remanded pending the gathering of further evi-

dence, and after a year's confinement was fined £100 and released. He retired to Agamenticus (now York), Maine, and in 1646 died poverty-stricken.

See the *New English Canaan,* edited by Charles Francis Adams (Publications of the Prince Society, vol. ix., Boston, 1883); C. F. Adams, *Three Episodes of Massachusetts History* (Boston, 1896); and, for a more favourable view of Morton, *A Few Observations on the Prince Society's Edition of the New English Canaan,* revised and reprinted from the *Churchman* (New York, 1883). Morton's adventures have furnished material for Nathaniel Hawthorne's short story, *The Maypole of Merrymount,* and for John Lothrop Motley's novels, *Morton's Hope* (1839) and *Merry Mount* (1849).

MORTON, WILLIAM THOMAS GREEN (1819–1868), American dental surgeon, was born at Charlton, Mass., on April 9, 1819, and studied dentistry at the Baltimore College of Dental Surgery. In 1844 he opened an office in Boston, where he gave especial attention to the improvement of artificial teeth and their means of attachment. It was necessary in many cases to remove the roots of old teeth, and in order to lessen the pain of this operation he searched for some means of deadening sensation. Dr. Charles T. Jackson (*q.v.*), a Boston chemist who already had made himself unconscious in the laboratory by inhaling sulphuric ether, suggested the use of this gas and demonstrated for Morton the method of inhalation. Morton first used it with success in the extraction of a tooth on Sept. 30, 1846, and on Oct. 16, 1846, he publicly administered ether at the Massachusetts General hospital while Dr. J. C. Warren performed a painless operation. Though Dr. Crawford W. Long (*q.v.*) had performed the first operation under ether in 1842, as subsequently revealed in 1849, it was Morton's independent discovery and his demonstrations which first made the value of sulphuric ether known to the medical world. He never benefited financially from his discovery and died in poverty in New York city on July 15, 1868. Morton published *Remarks on the Proper Mode of Administering Sulphuric Ether* (1847) and several papers in scientific journals.

MORTUARY, of or belonging to the dead, or in particular to the burial of the dead (Lat. *mortuarium,* from *mortuus,* dead, past part. of *morior*). The term was specially applied to the customary oblation or offering due from the estate of a deceased person to the church of the parish to which he belonged, and usually paid in kind to the incumbent. The parliament of 1529 (21 Hen. VIII., c. 6) limited the value of mortuaries to a maximum of ten shillings in estates exceeding forty pounds. Mortuaries, where customary, can be enforced only in the ecclesiastical courts: the custom is now obsolete, though claims have been made from time to time. The modern use of the word for a building in which bodies awaiting burial are temporarily kept is derived from the Latin *domus mortuaria,* mortuary house. But it has also been applied to many subjects connected with death and burial. In monastic institutions it was the duty of the almoner to send round to other monastic houses notice of the death of a member, asking for prayers for the soul of the dead. This notice was often beautifully illuminated. On being returned with the endorsement of the monastery to which it had been sent, it would be copied into the roll. Both the notice and the roll were known as a *mortuarium,* or mortuary.

See Abbot F. H. Gasquet's *English Monastic Life,* 1904.

MORVAN, an elevated region of gneiss and granite forming the northern continuation of the central plateau of France, and extending over a large part of the department of Nièvre, and over portions of those of Yonne, Côte-d'Or and Saône-et-Loire. Its area is a little over 1,000 sq.m. The average elevation is about 1,600 ft., the highest point, the Bois-du-Roi, attaining 2,959 ft. It is traversed by the Yonne, which has its source on Mt. Prénelay (2,789 ft.), by the Cure and by several affluents of the Arroux. It contains much good pasturage and is well wooded; the timber industry is important.

MORVI, a native state of India, in the Western India States agency, Bombay. Area, 822 sq.m.; pop. (1921), 91,355; tribute, £4,000. The chief, whose title is Thakur sahib, is a Jadeja rajput, of the same clan as the rao of Cutch. The chief products are cotton, sugar and grain. There is a state railway from Wadhwan to Rajkot. The town of Morvi is situated on the river Machhu, 22 m. from the sea and 35 from Rajkot; pop. (1921) 13,115.

MORYSON, FYNES (1566–1630), English traveller and writer, son of Thomas Moryson, M.P. for Grimsby, was a fellow of Peterhouse, Cambridge. He spent many years in travel on the continent of Europe, in Palestine and in Asia Minor. In 1600 he became secretary to Sir Charles Blount, lord-deputy of Ireland, where his brother, Sir Richard Moryson, held an appointment. In 1617 Moryson published an account of his travels and of his experiences in Ireland, where he witnessed O'Neill's rebellion, in a voluminous work entitled *An Itinerary.* He died on Feb. 12, 1630.

The *Itinerary* was originally intended to consist of five parts; but only three were printed, a fourth being preserved in manuscript in the library of Corpus Christi College, Oxford (partially printed in 1903 in Charles Hughes's *Shakespeare's Europe*).

MOSAIC, either a method, or the result produced by a method, of forming a surface by placing close together small pieces of marble, glass, tile, enamel, etc., usually for decorative effect. Mosaic is an outgrowth of inlay. In early periods of culture, small carvings of wood, stone or ivory were often decorated by inserting into them minute pieces of brilliant stone or enamel. When the area of such inlays is greater than the exposed area of the original material, which thus becomes merely a base and frame to hold the pieces of inlay, the result may be called mosaic. Many examples have been found in Egypt and Mesopotamia, dating from early cultural periods and chiefly ornamenting jewellery, furniture, small tablets and the like. The Egyptians had a certain grasp of larger possibilities for the material, as excavations at Tel-el-Yehudia in lower Egypt have revealed. Examples of column capitals and wall tiles show decorative richness where bits of coloured glass and earthenware have been inserted into sinkages in the tile or stone to form lotus and other ornaments. Recent discoveries in the Mesopotamian valley prove that the Sumerians had, at least as early as *c.* 3500 B.C., taken the next logical step in mosaic design and glued or cemented the small pieces of coloured stones to a base. A remarkable work in lapis lazuli and pink sandstone, excavated at Ur by the joint expedition of the British Museum and the University of Pennsylvania, is probably a standard, showing on one side an army going to battle, and on the other, a king or noble at a feast. This, probably dating from *c.* 3500 B.C., had the lapis lazuli and sandstone fastened to a wood background with bituminous cement. (See *Illustrated London News,* p. 1176, June 23, 1928.)

The Egyptians of the later empire apparently abandoned the use of mosaic except for jewellery, but in this they developed the amazingly skilful technique in glass mosaic, which is still employed in north Italy in making mosaic jewellery. This consisted of the use of small rods of coloured glass put together in such a way that their ends formed the desired pattern. The bundle thus made was heated, and so, partially fused together, drawn out while still hot to many times its original length so that at the centre, its section was but a small fraction of its original size. The whole was sliced, each slice giving a miniature reproduction of the original pattern. Thus, results of microscopic delicacy were produced, and the well known Egyptian skill produced coloured glass of great brilliance and variety; the most common colour was a greenish blue, widely used as a background.

Greek and Roman.—It is probable that the Greeks of the pre-Alexandrian period had developed at least the rudiments of mosaic technique, but it was only in the late Hellenistic era that this type of decoration became common. The name *opus Alexandrinum* (applied to one type, and its invention sometimes wrongly attributed to the emperor Severus Alexander), undoubtedly points to Alexandria as the great centre for work of this type. Few examples in Greece proper can be dated earlier than the Roman occupation. The House of the Trident of Delos shows exquisite examples of late Hellenistic mosaic. It is also a fact that in Pompeii, many of the finest examples of floor mosaics, such as the famous Battle of Issus, from the House of the Faun, date from as early as the 2nd century B.C.; and even the subject of this, unquestionably the most effective of ancient picture mosaics, with its representa-

tion of Alexander the Great, would seem to point to a Hellenistic origin and a Greek artist. In all of these early floor mosaics, the main body of colour is formed by tesserae, or small cubes, of carefully selected coloured marbles, but occasional bits of glass and tile are sometimes present.

Such large pictorial mosaics as the Battle of Issus in intricately worked detail, were exceptional in Roman floor mosaic work. Usually pictorial features were merely incidental panels in a much larger scheme of floor decoration, a type of design both more practical, and decoratively more satisfactory. Various types can be traced in the hundreds of examples of Roman floor mosaics preserved, not only in Italy, but in Syria, north Africa, France, Germany and England. The simplest, which from its common occurrence in even the most modest houses in Pompeii indicates an extremely inexpensive method of floor covering, consisted of an all-over simple geometric pattern, of two colours only. The tesserae of the background were of many shapes and sizes, put in almost at random, so that the effect approximated that of *terrazzo* (a cement coating embodying an aggregate of small pieces of coloured marbles, highly polished). The second class consisted of those in which a simple, central, rectangular field, usually light in colour, was surrounded by a decorative border of greater or less richness. These borders comprised some of the most effective mosaic designs of the time. In colour they were usually simple, often merely black and white.

Frets of all types were common, and the acanthus *rinceau,* or running scroll, was frequent, drawn in bold silhouette, with the utmost simplicity, appropriate to the material. In similar technique were the silhouettes of dogs, with the inscription *cave canem* ("beware of the dog"), that occasionally decorated vestibule floors. A third type comprised floors where the entire surface was made a rich decorative composition, usually by means of bold geometric patterns of considerable intricacy. Frequently, small panels of pictures were placed in important positions. It is to this type that the finest examples of Roman floor mosaic belong, such as the remarkable series found in and near Carthage, with their simple representations of men fishing, and other similar *genre* subjects, and the great mosaic from the baths of Otricoli, now in the Sala Rotunda in the Vatican. The last class is that of the frankly pictorial mosaic, undoubtedly based on Greek precedent. The famous "unswept room," now in the Lateran Museum, with its litter of fish, vegetables and fruit, and its mouse gnawing a nut, was copied or adapted from a well-known Hellenistic original at Pergamum.

Another type of floor treatment was the large-scale marble mosaic, *opus sectile.* In this, large slabs of coloured marbles, circular or square, were used to form magnificent and simple all-over patterns, usually with an alternation in adjacent units, of square and circular forms; there was sometimes, also, an additional alternation in colour. The most famous example, unique in being still in place and in use after more than 1800 years, is the great marble floor of the Pantheon, at Rome (begun 110), whose alternating squares and circles have been the inspiration for countless marble floors in modern days.

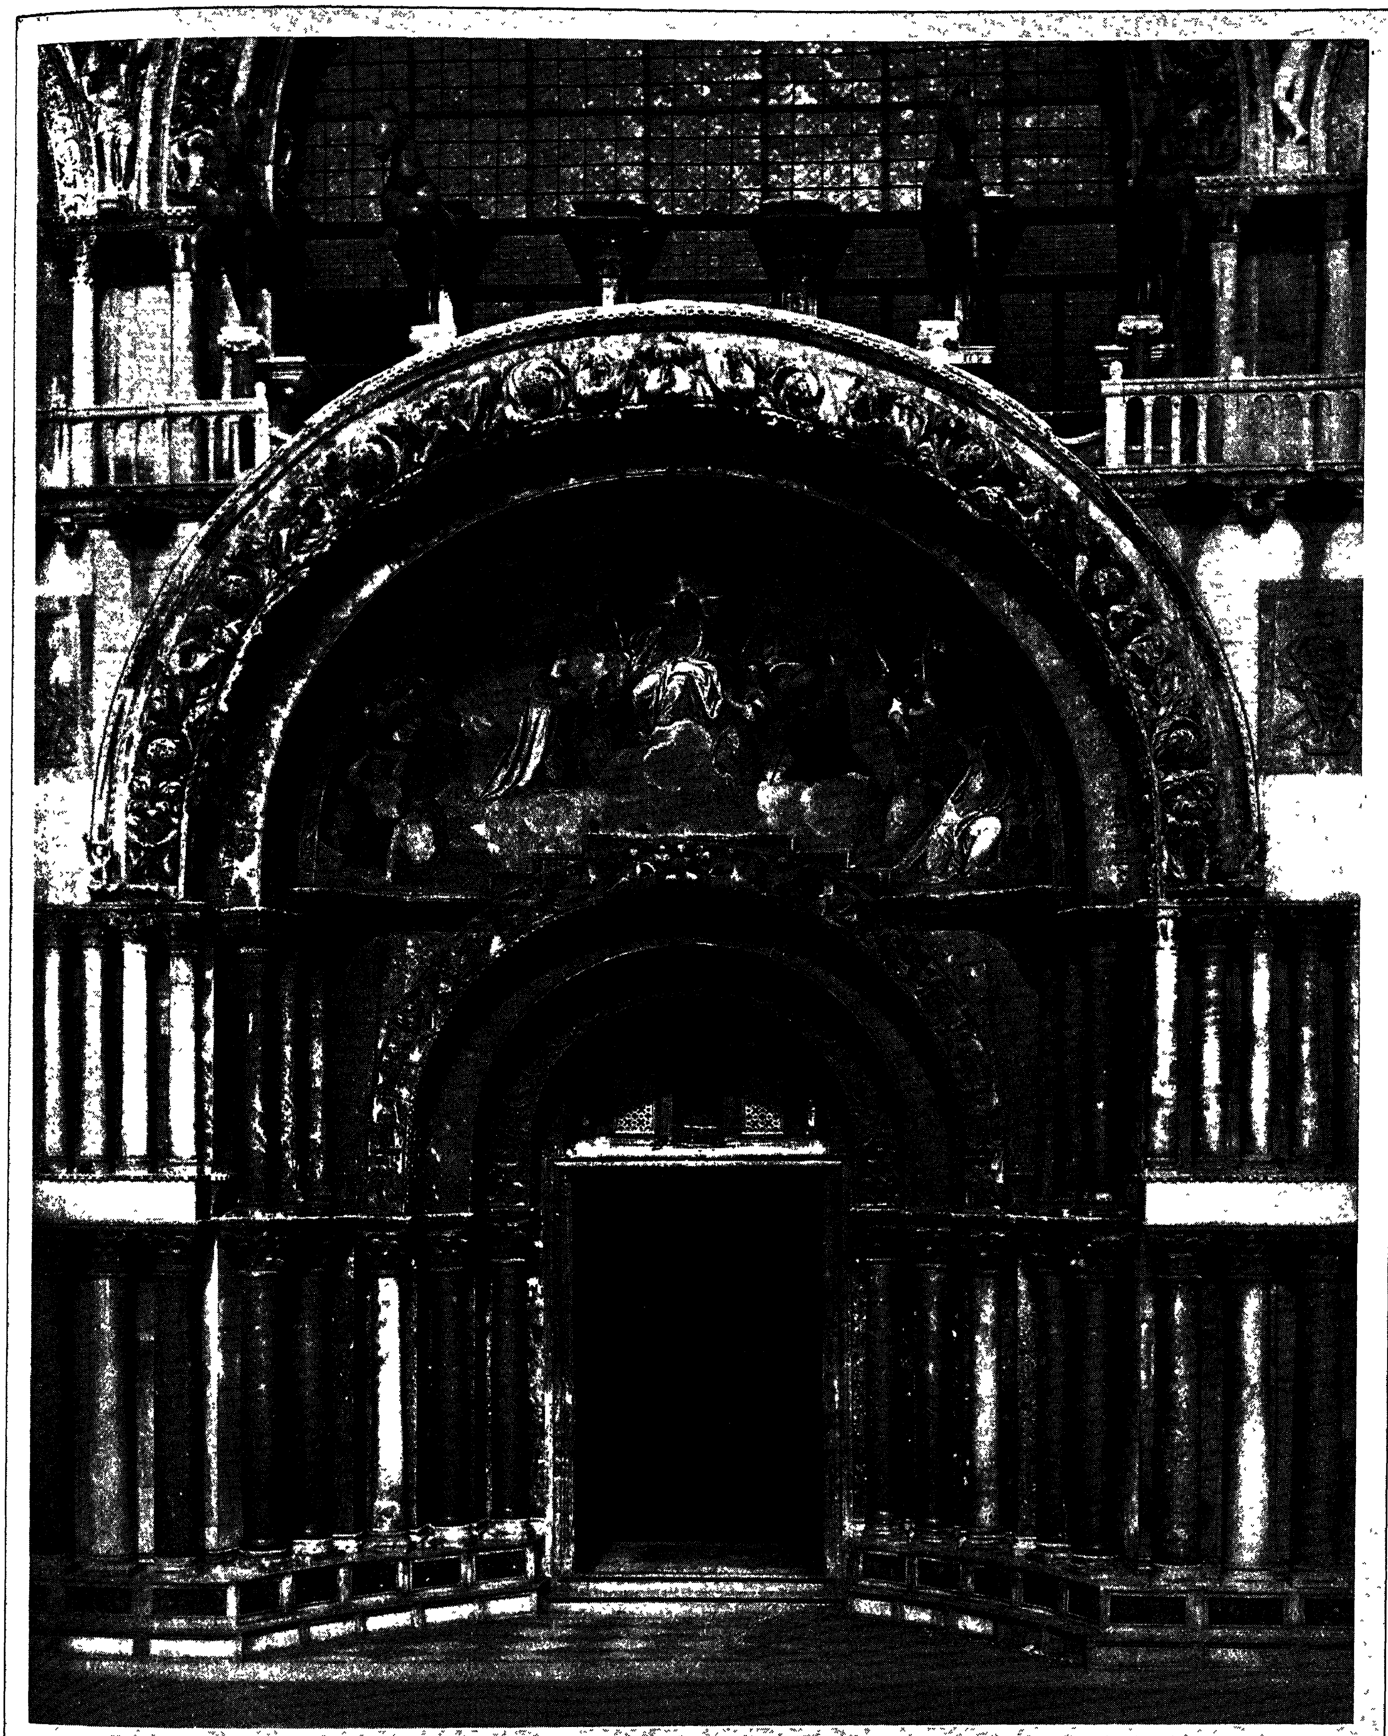
It is known from literary sources that mosaics, chiefly of glass, were much used also on the upper walls and vaults of monumental buildings of the Roman empire. Unfortunately, few, if any, examples of vault decoration earlier than the 4th century remain, and none *in situ.* Pompeii, however, has furnished several instances of more informal uses, especially mosaic columns and several mosaic garden fountain niches. Certain small panels of fine scale, and exquisite draughtsmanship, such as the two panels of rabbits in the Metropolitan Museum, New York, may have been used on walls rather than floors. It is noteworthy that the Pompeiian columns and fountains already show certain features characteristic of later Byzantine mosaics, both in the roughness of the texture, and in the colouring, largely blue-green. Column patterns seem to have been based on textile motives. The finest example of classic Roman vault mosaic is that in the aisle of S. Costanza (dated by Rivoira 324–326). Portions that remain are remarkably rich, varied and skilful in design; parts have leaves; birds and fishes are scattered over a light ground with lavish informality; and other parts show interlacing, geometric patterns. The most famous fragment represents a vintage scene, with the grape gatherers climbing through the vines, whose supporting lattice forms an interesting geometric basis.

In the 5th century mosaics of the tomb of Galla Placidia (*c.* 440) and the baptistry of Neon (5th century), both at Ravenna, the rich mosaics covering walls and vaults still remain dominantly classic and Roman, although elements characteristic of later Byzantine work had appeared. Those of the baptistry, with their great swirling acanthus *rinceaux* in the lower arch spandrils, and the rich architectural ornament of columns and shell-topped niches, at the base of the dome, and the garland or wreath on the under side of the entrance arch of the tomb of Galla Placidia are especially important in showing what must have been the character of the monumental Roman mosaics of the earlier period.

Byzantine.—By the middle of the 6th century, the Byzantine technique of design and execution had become definitely differentiated from the earlier Roman and transitional types. Not only did Byzantine domical design and the flatness of architectural forms give enormous scope for mosaic decoration in church interiors, but also, the very crudities of Byzantine execution, became, themselves, valuable aids to the development of mosaic design. Thus no imitation of painting was possible; crudities in drawing became interesting decorative conventions, admirably fitted to mural decoration; growing roughness of texture gave a play of light and shade that brought out in a new way the possibilities and characteristics of the material. Moreover, the use of gold tesserae, made by compressing gold leaf between two layers of glass, became increasingly common, and gave to the result a tremendously scintillating and vibrant quality. The mosaics of the triumphal arch and apse of S. Vitale, at Ravenna (*c.* 547) are characteristic of the earlier type of developed Byzantine mosaic. The grouping of the figures has just the right decorative rigidity, and the faces are drawn with impressive simplicity. Medallions, groups and decorative features are composed with richness and dignity. Gold and silver were used sparingly. Similar characteristics appear in the earlier Roman mosaics in the triumphal arches of St. Paul's Outside the Walls and S. Maria Maggiore (both 5th century), and remain constant in Italian Byzantine mosaic work well into the 13th century as in the apses of St. Paul's Outside the Walls (13th century) and of S. Maria in Trastevere, the upper part of the 12th century, the lower part by Pietro Cavallini (1291).

The most typical, and in some ways, the most remarkable production of the Italian school of Byzantine mosaic are the half-dome mosaics of the apses of the Roman basilicas. In these, not only is the stylization of the figures themselves entirely satisfactory, but also, the naïve directness of the composition and the simple symbolism of the ornament combine to create reverent and charming beauty. In general, the upper portion of the apse dome is occupied by a half rosette which may embody a symbol of deity. Below, filling the greater part of the curve, stand the figures, varying in number with the subject, but usually the central figure is that of Christ or the Virgin Mary, or, more rarely, the patron saint. Sometimes the figures are in a symbolic landscape, with a river below, and trees on the sides; occasionally, as a base to the composition, there is a row of lambs, representing the souls of the saved, facing a central lamb, carrying a cross and banner and symbolizing Christ. In addition to the examples already mentioned, those of SS. Cosmas and Damian (6th century), S. Agnese Outside the Walls (626) and St. Marco and S. Cecilia in Trastevere (both 9th century) are noteworthy. The apse of S. Clemente (12th century) and of S. Maria Maggiore (13th century) are exceptional; the former, in its bold covering of the dome surface with vine patterns which are, in essence, merely variations of acanthus *rinceaux;* the latter, because of the new spirit resulting from its design by Jacopo da Turrita and Taddeo Gaddi, whose work is more in the line of descent of later Italian painting than of Byzantine mosaic.

Meanwhile, in Constantinople, a different school of Byzantine mosaic had developed. Its earliest great monument, the decoration of S. Sophia (middle 6th century) still remains one of its most



PHOTOGRAPH, ALINARI

PRINCIPAL DOORWAY OF ST. MARK'S IN VENICE

The technical skill of the Byzantine mosaicists was preserved in Venice for centuries, but the decorative genius of the earlier designers decayed swiftly, and by the 16th century—the period of this mosaic—only sterile and clever attempts to imitate paintings were produced. A comparison with fig. 2 on Plate II. reveals at a glance the decorative feebleness of this mosaic

MOSAIC

BY COURTESY OF (1) P JACKSON HIGGS, (2, 6) THE RAVENNA MOSAICS, INC ; PHOTOGRAPHS, (3, 4, 5) ALINARI

PERSIAN AND BYZANTINE MOSAICS

1. Persian faience mosaic from a tomb at Ola, an example of the richness of architectural treatment by the use of ceramic tiles, which was a dominant feature of Persian architecture (*see* TILE). The type of design shown here is that developed at Isfahan, in the year A.H. 885, or A.D. 1482.

2, 5 and 6. Byzantine mosaic at its best. (5) is from the church of S. Apollinare Nuovo, in Ravenna, and dates from the 6th century. Its simple row of ranked saints, so dignified in their powerful restraint, becomes one with the wall it decorates; it is an essential part of the architecture of the building, as firm, as constructive, as the columns and arches below. (2) and (6) face each other from opposite sides of the apse walls of S. Vitale at Ravenna; they, also, date from the 6th century. Less formal than the saints of (5) they still preserve that rhythm, balance, and simplicity of composition that constitute the essence of harmonious architectural ornament. The exact and desirable balance between representation and conventionalism, between pictorial vividness and rigid architectonic quality has seldom been so perfectly achieved. In them is the richness of the Byzantine court, yet they always remain essentially parts of the wall, and essential units in the architectural design

3. The apse mosaic from Sta. Maria in Trastevere, Rome, one of the richest and most satisfactory examples of the work of the 12th century Roman mosaicists. This work, usually classed as Byzantine, combines with strict Byzantine decorative composition a more Roman quality of freedom; a late classic influence is revealed in the shell-like form at the top, and the rich border on the arch

4. This 12th century mosaic from the Capella Palatina (the chapel of the Royal palace) in Palermo, Sicily, showing the angel visiting St. Peter, reveals the increased pictorial quality of the later Byzantine mosaics

effective achievements, and although it is contemporary with the work in S. Vitale, already mentioned, it is strikingly different, both in composition and effect. The novelty appears in the use of gold mosaic as a background for all of the decorative work covering the vaults and the large scale and oriental, non-classic type of ornament; and although the figure work is now covered with Turkish plaster and paint, the portions still exposed give an effect of unrivalled, solemn richness. In general, domes and vaults are treated simply, with large areas of gold and borders, and occasional spots, of direct and simple ornament, often geometric, with occasional leafwork in which forms almost Persian appear. In the pendentives are great figures of the cherubim, represented merely as six great wings, magnificently filling the space in soft bluish grey. Between the windows of the large side arches, and in the apse were the figures now covered up. These have, however, been studied during an examination of the building for its stability under Sultan Abdul Medjid (1847–49); the mosaics were at that time carefully drawn by the Italian architects in charge, the Fossatis, so that it is possible to form a perfect conception of the original appearance. (*See* C. G. Fossati, *Aya Sophia,* 1852.) The most effective of the mosaics still exposed are those of the vaults of the narthex, the gallery immediately above it, and the cherubim in the pendentives.

The precedent of gold grounds set by S. Sophia, controlled, not only all the mosaics of Constantinople and the adjacent regions, for the next 700 years, but is also responsible for the gorgeous interiors of Monreale cathedral, 1170–90, and La Martorana and the Capella Palatina (both in Palermo, 12th century). To it is also due the use of the single great head or figure of Christ in the apse, a type of religious decoration whose awe-inspiring grandeur and daring beauty can best be judged at Monreale. Similarly, the ranked figures over the columns of the nave of the Capella Palatina, recall, distantly, the saints between the windows of the arches of S. Sophia. Even in Venice, the Italian school of Byzantine mosaic is entirely dominated by that of Constantinople, and the narthex and baptistry of St. Mark's (13th century), resemble the oriental patterns of Constantinople much more than the contemporary work in Rome. The vaults and domes of the main body of the church, with glorious gold backgrounds, are equally eastern, but the figures and scenes, dating from the 12th to the 16th century, have been so repaired, altered and polished, and in parts, so disfigured by the Renaissance effort to imitate paintings with an alien material, as to be individually disappointing.

The Constantinople tradition even permeated Mohammedan countries. Thus the entire mosaic decoration of the Koubet-es-Sakra (or dome of the rock) and the El Aksa mosque, both in Jerusalem, were executed by Greek artists, invited to Jerusalem specifically for that purpose. Those from the Dome of the Rock date largely from *c.* 694, with portions from the reconstruction under Saladin in 1187. Those from El Aksa are principally of Saladin's time. Even in Cordova, Spain, Greek artists, brought there by Abd-er-Rahman III., decorated the mihrab of the Great Mosque with rich floral mosaics (929–961).

Although in Europe, Byzantine mosaic passed into decadence in the 13th and 14th centuries and finally disappeared, through the tremendous development of the magnificent school of Italian mural painters, in Constantinople and Greece, mosaic remained the dominant church decoration until the fall of Constantinople (1453). The mosaics of the church of the convent of Daphni, near Athens (*c.* 1100), are interesting examples of the middle period. In Constantinople great areas of mosaics still remain in churches converted into mosques; only in two cases are these exposed: one is a beautiful ribbed dome in the Fetihieh Djami, originally the church of Pammakaristos (12th century), the other, and more important example, is the rich 14th century decoration of the Kahrieh Djami, once the church of the Chora; these show that in the 14th century the earlier hieratic stiffness of figure drawing, and the almost mechanical regularity of composition, decoratively so impressive, of the earlier period, was giving way to a much more pictorial ideal. There are not a few resemblances between some of the scenes here and the almost contemporary decoration in fresco of the church of St. Francis at Assisi. The borders and the ornamental details retain, however, their old character, and the gold ground, and the roughness of texture, still make these decorations essentially mosaic in character, and not the imitated paintings of the later work at St. Mark's at Venice.

Mediaeval Italian.—The opus sectile of Roman marble floors had an equally distinguished mediaeval development. This came through the combination of opus sectile, in which large slabs of coloured marble were cut to a pattern, with opus Alexandrinum, a form of mosaic consisting of many small pieces of marble cut to constant "stock" shapes. These shapes are: right angle and equilateral triangles, lunettes and squares, by the combination of which all sorts of geometric patterns could be obtained. The colours most common are red, dark green, white, black and occasionally creamy yellow. The most usual pattern is that obtained by inscribing in a large triangle, smaller triangles of alternating dark and light colours. With opus Alexandrinum, continuous bands were formed which were inset into the opus sectile to make borders for panels, or running interlaces and guilloches (*q.v.*). The effect thus achieved of contrast of large and small scale was extremely impressive and there was an indefinite supply of coloured marble to be had for the taking from pagan Roman buildings. The circles so frequently used were made by slicing Roman columns. The use of this type of pavement is so common in Italy as to make it difficult to select examples; those of St. Mark's, Venice, and S. Maria Maggiore, S. Maria in Trastevere, and S. Clemente, all in Rome, are particularly striking. The decorative possibilities of this combination of opus sectile and opus Alexandrinum were recognized during the 12th, 13th and 14th centuries for the decoration of altar frontals, ambones, choir screens and parapets. Rome and south Italy are particularly rich in examples (*see* AMBO). Roman workers in this type of mosaic evidently travelled widely, for in Westminster abbey the space in front of the high altar was decorated with it in the third quarter of the 13th century by a Roman artist named Odericus.

In using opus Alexandrinum for church furniture a continual decrease in the size of the units, and an increased delicacy in the scale of the pattern was obtained. In this development it was but natural to substitute glass or enamel, in some cases, for the earlier marble, and it is this type which is known by the name of the family that, during the 13th century, was its chief exponent—Cosmati work. Its use was not limited to flat surfaces. Frequently the spiral columns, then so popular, had grooves cut in the hollow spiral flutes, which were filled with Cosmati mosaic of exquisite delicacy. This is the case in the 13th century cloisters of St. John Lateran and St. Paul Outside the Walls, both at Rome, in the paschal candlestick at S. Clemente, Rome, and in much church furniture in the south of Italy. Without doubt, work of this kind was common in the 13th century all over Europe and mosaic patterns probably exerted a large influence upon the other arts, especially in the case of enamel work on metal. In Westminster abbey the shrine of Edward the Confessor (1269), and the tomb of Henry III. (1291), are both remarkable examples of rich Cosmati work outside of Italy; they were the work of one Peter, a Roman citizen, who was possibly a pupil of the Cosmati.

Mohammedan.—In Mohammedan countries mosaics of the Byzantine type were little imitated by native artists. In Persia a type of mosaic occurs in exterior design, which seems to be either of independent origin, or else due to a distant memory of the burned and glazed brick and tile wall coverings of Assyrian palaces. Small rectangular tiles are put together to form geometric patterns, some of which are based upon rectangularized versions of Arabic letters. The most remarkable examples are those of the mosque at Veramin (early 15th century), the mosque of Chah-Sindeh at Samarkand (1392), and certain details of the tomb of Princess Tchuchuk Bika, at Samarkand (1371). A similar technique is used in the decoration of the great entrance arch and loggia of the Chinili Kiosk in the seraglio at Constantinople, designed by Kemal-ed-din (1466–70). In Persia itself, however, continually increasing skill in painting faïence tiles with floral pat-

terns led gradually to the abandonment of mosaic in favour of the newer and richer method.

Mohammedan architecture of India developed under the Moguls a tremendous skill in an elaborate marble mosaic of opus sectile type in which the most intricate curvilinear patterns are formed in the cut marble, and colour is furnished by the rich use of precious and semi-precious stones, as well as coloured marbles and enamel.

Another characteristically Mohammedan development is that of small scale geometric mosaic in wood, for the decoration of furniture, boxes and implements. This art was especially practised in Cairo, Damascus and north India and persists in parts of the Mohammedan world to the present day. Frequently ivory and mother-of-pearl are combined with different coloured woods in the patterns. A similar technique is employed to-day in parts of Italy. No definite line can be drawn between wood mosaic of this type and that which is known as marquetry (*q.v.*). Similarly the quasi-mosaic work in wood inlays, known as intarsia, of which the most remarkable example is the choir stalls of the church of S. Pietro Casinensi, at Perugia, from designs said to be by Raphael, executed by Stefano da Bergamo (1535), is more truly marquetry than mosaic.

Modern.—With the coming of the Renaissance, mosaic art almost completely disappeared, and where mosaic was used by Renaissance decorators, such as the work of Titian in St. Mark's at Venice, it was merely an attempt to imitate painting. Only in Venice, in the form of jewellery and similar small work, did the vitality of the art continue. There, at least in technique, it seems to have persisted down to modern times, although in design following the fashion of the day. It was not until the revivals of the 19th century that mosaic art resumed any importance whatsoever as mural decoration. The tendency toward decorative lavishness, so characteristic of the Gothic revival, was peculiarly fruitful in resurrecting the art. Almost all of the middle 19th century work is Venetian, and much of it produced by Antonio Salviati. The mosaics of the central hall of the houses of parliament, at Westminster, from designs by Sir Edward Poynter, and those of the reredos of Westminster abbey (1867) are typical. They show the great fault common in these revival mosaics—a surface polished smooth, tesserae so close together that joints between them become almost invisible, and design which neglects the material and aims principally at pictorial effect. Even in the much more successful mosaics from the designs of Sir Edward Burne-Jones, in the American church at Rome, the surface is too smooth to bring out the maximum decorative effect. Similarly, in France, the mosaics of the ceiling of the Escalier Daru, by Lenepveu, the apses of the Madeleine by Gilbert Martin and the Pantheon, by Hébert, show the same fault of texture, though in design revealing the customary brilliance of French mural decoration. During the present century the decorative possibilities, as well as the limitations of the material have come to be more thoroughly recognized, and work as different as that of the Giggleswick school chapel in England, by Sir T. G. Jackson, and the extremely modernist Golden hall in the town hall of Stockholm, by Ragnar Ostberg, alike show a true grasp of the necessity of keeping surfaces rough, drawing simply and allowing the cement in the joints between the tesserae to count as part of the decorative effect.

In the making of the best modern mosaic two general methods are employed. In one, the tesserae are fixed in place by hand, on the wall or vault itself. This is, undoubtedly, the most direct method, and allows the light on each piece to be studied in place. The more common technique is to prepare an outline drawing on heavy paper, which is the reverse of the full size cartoon for the design. Upon this the tesserae are glued in place. When this process is completed, the paper is cut into pieces small enough to be handled easily. The wall to be decorated has in the meanwhile been brought to a perfect surface with a special cement. Fresh cement is placed over this surface, and into it are pressed the tesserae with their faces still glued to the original drawing; when the cement has sufficiently set, the paper is torn off, the joints pointed with cement and the whole cleaned. This method allows the choice of the tesserae and their arrangement to be accomplished at leisure in a studio. If carefully handled with the necessary changes, when the tesserae are in place, slight errors may be satisfactorily corrected, although certain critics maintain that the best results can only be obtained by the direct application of the tesserae to the wall. In recent years new effects have been obtained by leaving the background entirely in cement, only the figure, or pattern itself being in mosaic.

Another strictly modern development of mosaic has resulted from the use of small tiles for floors, wherever ease of cleaning is imperative. Thus mosaics of small, vitrified tile, in uniform shapes—especially squares, hexagons and circles, or of small rectangles arranged in a basket weave design—are common, not only in the halls of tenement houses, public buildings, etc., but also on the floors and as wainscoting in baths, toilet rooms, lavatories, swimming pools and even kitchens.

Modern decorative mosaic floors are largely based on the opus sectile of Roman imperial work, and especially in churches, upon those combinations of opus sectile and opus Alexandrinum so characteristic of mediaeval Italy.

MOSBY, JOHN SINGLETON (1833–1916), American soldier, was born in Edgemont, Va., on Dec. 6, 1833. He graduated at the University of Virginia in 1852, was admitted to the bar in 1855 and practised in Bristol, Washington county, Va., until the beginning of the Civil War. For a time he was adjutant of Gen. J. E. B. Stuart's 1st Virginia Cavalry. In 1863 with Stuart's permission he undertook a quasi-independent command. In Fairfax, Fauquier and Loudoun counties within the Federal lines, he raised and equipped a force of irregulars. On the night of March 8, 1863, with about 30 men, he penetrated the Federal lines at Fairfax Court-house and took 33 prisoners, including Brig.-Gen. Edwin H. Stoughton. He became famous for other such exploits. In the North he was regarded as a guerilla and in 1864, Sheridan, under orders from Grant, hanged seven of Mosby's men without trial; Mosby retaliated by hanging seven of Custer's cavalrymen. On April 21, 1865, 12 days after Lee's surrender, he disbanded his men. Through the influence of Gen. Grant, he was paroled. He returned to his legal practice, joined the Republican Party, canvassed Virginia in 1872 for Grant. In 1878–85 he was U.S. consul at Hongkong, and was assistant attorney in the Federal Department of Justice from 1904 to 1910. He wrote *Mosby's Reminiscences and Stuart's Cavalry Campaigns* (Boston, 1887) and

Scott, *Partisan Life with Mosby* (New York, 1867).

MOSCHELES, IGNAZ (1794–1870), Bohemian pianist, was born at Prague on May 30, 1794, and studied music at the Conservatorium under Dionys Weber. He made his name in 1815 with his *Variationem über den Alexandermarsch.* He then toured the capitals of Europe as a pianist. During a visit to Berlin in 1824 he met Mendelssohn, then a boy of fifteen; and a friendship sprang up between them which was severed only by Mendelssohn's early death (see *Briefe von Mendelssohn-Bartholdy an Ignaz und Charlotte Moscheles,* 1888). In 1826 Moscheles married Charlotte Embden at Hamburg, and settled permanently in London. He was a brilliant executant, who interpreted the works of the great masters with conscientious fidelity. In 1846, at Mendelssohn's earnest solicitation, he removed to the Leipzig Conservatorium, then recently founded. Moscheles died on March 10, 1870. His numbered works extend to 142, apart from minor pieces; his most important compositions are his Pianoforte Concertos, Sonatas and Studies (*Études,* op. 70; and *Characteristische Studien,* op. 95); *Hommage à Händel;* and his three *Allegri di bravura.*

See *The Life of Moscheles* (1873), a translation by A. D. Coleridge of Mme. Moscheles' *Aus Moscheles Leben* (1872).

MOSCHEROSCH, JOHANN MICHAEL (1601–1669), German satirist, was born at Willstädt, near Strasbourg, on March 5, 1601. He was educated at Strasbourg, and after various appointments in different places, became privy councillor to the landgravine of Hesse-Cassel. He died at Worms on April 4, 1669. His most famous work is the *Wunderliche und wahrhafftige Gesichte Philanders von Sittewald* (anagram of Willstädt) (1641–1643), for which he took as his model the *Sueños* (visions) of the Spaniard Gomez de Quevedo y Villegas. Hardly inferior to the "visions" is the *Insomnis cura parentum, Christliches Vermächtnis eines Vaters,* (Strasbourg 1643 and 1647). Noteworthy is also *Die Patientia,* discovered in 1897 in ms. in the municipal library at Hamburg.

Selections from Moscherosch's writings have been published by W. Dittmar (1830), F. Bobertag (in Kürschner's *Deutsche National-literatur,* xxxii., 1884), and K. Müller (in Reclam's *Universalbibliothek*). Reprints of the *Insomnis cura parentum* and *Patientia* have been published by L. Pariser (1893 and 1897), who is also the author of *Beiträge zu einer Biographie von Moscherosch* (1891). *See* also M. Nickels, *Moscherosch als Pädagog* (1883); J. Wirth, *Moscherosch's Geschichte* (1888); and bibliography by A. Bechtold, *Kritisches Verzeichnis der Schriften J. M. Moscherosch* (Munich, 1922).

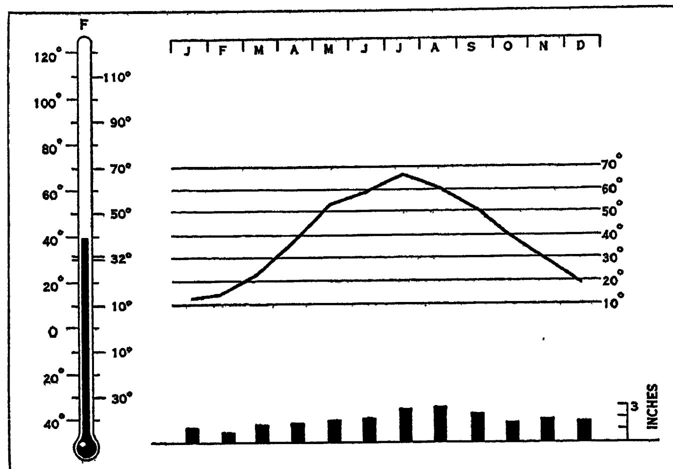
MOSCHUS, Greek bucolic poet, was born at Syracuse and flourished about 150 B.C. He was the author of a short epic poem, *Europa,* and a pretty little epigram, *Love, the Runaway,* imitated by Torquato Tasso and Ben Jonson. The epitaph on Bion and the *Megara* are probably not his, but a few other pieces, undoubtedly genuine, have been preserved. His poems are nearly all in hexameters. They are usually printed in editions of Bion and Theocritus.

The text has been edited by U. von Wilamowitz-Möllendorff, in the Oxford *Scriptorum classicorum bibliotheca* (1905); and in the Loeb *Classical Library,* with translation, in *The Greek Bucolic Poets* (1912); there are English translations by J. Banks in Bohn's *Classical Library* (1853), and by Andrew Lang (1889).

MOSCOW (Russian Moskvá), a province of the Russian S.F.S.R., surrounded by those of Smolensk, Tver, Vladimir, Ryazan, Tula and Kaluga, area 44,980 sq.km.; pop. (1926) 4,534,133. The province is of peculiar interest as the cradle of the "Great Russian" nation which rose after the decay of Kiev. It consists largely of the inter-riverine ("Mesopotamia" in Russian "mezhdurechie") district between the upper Oka and the upper Volga, with the Moskva river flowing through its core to join the Oka. To the west of the province there was a convenient portage between the Moskva and the upper Volga, on which was situated the fiercely disputed Novgorod trading colony of Volok-Lamsk, through which the railway from Moscow to Rhzev now passes.

The region was always densely forested, and even to-day forest occupies 42·7% of the province. The climate is continental, the rivers are frozen for 153 to 160 days, average January temperature 14° F, July 66·5°, snow lies thickly in the winter, and the average precipitation is 21·0 in. per annum, the prevailing winds being southerly and south-westerly.

The province consists of undulating ground (500–850 ft.) with



WEATHER GRAPH OF MOSCOW. THE THERMOMETER INDICATES THE ANNUAL MEAN TEMPERATURE. THE CURVE SHOWS THE MONTHLY MEAN TEMPERATURE. THE COLUMNS INDICATE THE NORMAL MONTHLY PRECIPITATION

broad valleys carved out by the rivers. In the Tertiary period it was already continental, but was partly submerged by the Cretaceous sea. There are no Triassic or Permian deposits, and the Jurassic is represented by its upper formations only. Upper Carboniferous deposits of deep sea origin rest upon the Devonian, discovered in an artesian well at Moscow at a depth of 1,508 feet. The pendulum anomaly, mentioned by Kaspar Gottfried Schweitzer (1816–73), appears in a zone 10 m. wide and extending for about 95 m. from west to east, and is positive (+10·6″) to the north of Moscow and negative (−2·7″) to the south.

Industries.—Coal, of low calorific value, is mined; and in early times the forest and this coal provided fuel for the industries which sprang up around the market at Moscow, where the first fur-preparing and cloth factories were established. The making of textiles began first in the peasants' huts, and even to-day peasant textile industries are widespread in the province and flourish in spite of the great development of the factory textile industry.

In early times a heavy metal industry existed in the district, but with the development of the Ural mining and metal industry it died down in view of the poor fuel supply. In 1876–80, the coalfields to the south of Moscow province provided 15·7% of the coal raised in Russia, but with the introduction of cheap transport on the Oka and Volga for the Don coal and Baku naphtha, the Moscow textile industry ceased to rely on local fuel and the production in 1911–15 was ·7 of the Russian total. After the outbreak of war in 1914, an impetus was again given to the use of local coal which provided 700,000 tons in 1916–17.

Since the 1917 revolution efforts have been made to overcome the fuel deficiency of the industrial regions of the province by the provision of electric power. Peat is abundant and an electric plant at Bogorodsk, east of Moscow, works on peat fuel, while the famous Shatura station, opened in 1925–26, working on peat had a power of 92,000 kw. in 1928, which is planned to be increased to 136,000 kw. in 1929. At Kashira, south of Moscow, a station works on local coal, power in 1928, 34,000 kw., planned to give 78,000 kw. in 1929. Another station works on naphtha and anthracite and the R. E. Klasson electric station had a turbo-generator installed in 1925–26 giving 16,000 kilowatts.

There are intensive textile industries, especially cotton and chintz, with woollens, linens, silk and silk ribbons. Dependent on

these are factories producing dyes, spools, reels, machinery for the textile factories, buttons, needles, ready made clothing and knitted garments. A cellulose industry is developing at Dmitrov, and silicate, cement and machinery industries at Podolsk, near which phosphorite is found. Guns and rope are manufactured at Kolomna. Other factories produce glass, bricks, tobacco, confectionery, alcoholic drinks, leather, galoshes and fur garments. Serpukhov undertakes iron and copper smelting.

Agriculture has been much influenced by its nearness to the great population centre at Moscow. Before cheap corn was imported from the newer grain-growing regions, grain was grown for the Moscow market in spite of poor soil conditions and low yields per acre, but a marked diminution then set in and in 1909–1913, the area under grain crops was a very small proportion of that in 1887. A many field grass system now prevails in place of the old three field system, and much attention is devoted in the regions near the towns to the production of potatoes, cucumbers, cabbages and onions, and also to fruit growing, especially cherries, raspberries, strawberries, gooseberries, currants and plums. Some collective agricultural artels exist.

Intensive dairying is carried on for the town markets, and pig breeding is developing in dependence on it. Flax, which demands much labour, is diminishing rapidly in spite of the factory market, because available peasant labour tends to be absorbed in the factories. The chief grain crops are rye and oats, with a little buckwheat.

The chief towns are Moscow, Orekhovo-Zuevo, Serpukhov, Bogorodsk, Egorievsk (Yegorievsk), Sergiev and Pavlovo-Posad, *qq.v.* Communications are the best in the country; a network of navigation, railway routes and roads concentrates on the town. This fact and the lessened costs of transit from Siberia, the Central Asiatic region, the Caucasus, and the productive regions of the south enabled the industries of the province to survive the development of St. Petersburg (Leningrad) as an industrial centre.

The district has been inhabited since the Stone Age, though bronze implements are rare. In some places stone, bone and iron implements have been found together. Burial mounds of the 10th and 12th centuries seem to be of Finnish origin. Finnish tribes certainly occupied the district at the time of its colonisation by the Slavs, and some racial intermixture took place, thus somewhat emphasizing the difference between Great Russians and Little Russians, the latter of whom have intermingled with the Tatars.

MOSCOW, the capital of the Union of Socialist Soviet Republics and of the Russian Socialist Federative Soviet Republic, situated in the Moscow province, on both banks of the navigable Moskva river, a tributary of the Oka, in 55° 45′ N., 37° 37′ E. Pop. (1926) 2,019,453. In 1156 George Dolgoruki, prince of Rostov, founded the town, probably by erecting wooden walls round his villa and estate and its dependent settlements, which were situated on the hill at present occupied by the Kremlin. This patch of the virgin pine forest had been cleared but recently, and the little church of the Saviour in the Wood, the oldest building in Moscow preserves the memory of the forest clearing. Even in those early times its site had some trading importance and rough tracks, the precursors of the modern roads and railways, linked it with Kiev and old Novgorod, while the Moskva river linked it with the Volga and the south and east. Ivan Kalita, Ivan I., (1328–41) laid the foundations of its future financial importance by acting as tax-gatherer for the Mongol Horde, thus placing the east Russian princes in a position of dependence on Moscow for security from Tatar raids. Under Ivan III. (1462–1505) the conquest of Kazan and Astrakhan opened a trade route from Moscow to central Asia and Persia, and another route was opened through the White sea to western Europe, while the gradual development of western Siberia following on Yermak's expedition of 1582 added further sources of trade. In the latter half of the 19th century began the construction of railways and the development of industry in the Ukraine and on the Caspian, leading to the supply of coal and naphtha for the industries of Moscow. Thus Moscow to-day is the centre of the trade, industry and culture of Russia.

A seventh part of all Russian trade passes through the capital and eleven railways radiate from it, bringing it into communication with Vladivostok and the Pacific, with the central Asiatic republics, with the Black sea and the Caspian, with Leningrad and the Baltic, with Murmansk and Archangel and the Arctic ocean. The Soviet Government is collecting data as to the possibilities of a river and canal link between Moscow and the Pacific (1928) and air communications are bringing Moscow into even closer communication with the rest of Russia and the outside world. The Russian Volunteer Aviation Company, organized in 1925, is expanding the air-routes from Moscow. A bi-weekly service goes to Nizhni-Novgorod and there are routes to Kharkov and Odessa, and projected routes to Yakutsk, Vladivostok and other distant centres. The Russo-German air-fleet has regular services between Moscow and Berlin.

Moscow's industries are mainly textiles, metallurgy and the production of foodstuffs; its factories number 794, and its trading enterprises, 16,407. The marked development of electrification since 1924 is solving the difficulty of inadequate fuel, and giving a fresh impetus to production. Among new industries are the production of glass machinery of the Furko type, agricultural triers, manometers, chrome leather, and glass for clocks and automobiles. There is an excellent tram and bus service and some part of the local railways is electrified. Proposals for an underground railway are being considered, though as yet there is little traffic congestion in the streets, since the general level of poverty does not allow of private motor cars except for a few Government officials. The rapid increase of population consequent on the return of the administration to Moscow since the 1917 revolution, and the great influx of peoples from the varied regions of the vast empire has created a sharp crisis in housing accommodation, which was sadly inadequate even in 1913. In 1923 only 8% of the population had one or more rooms, 54·7% were living 2 to a room, 31·8% five to a room and 4·9% more than eight in one room. In spite of these terrible conditions, great advances in sanitation and the care of children have resulted in a marked diminution of the mortality rate.

In appearance the city presents a striking summary of the national life, the wooden houses of the suburbs reminiscent of the peasant *izba* of the villages, the low built houses of the former aristocracy with their pillar-porticoes, the many storeyed modern flat dwellings, the huge factories, the oriental splendour of the gilded and painted domes of the churches and cathedrals and the magnificence of the former imperial palaces, alongside of which are the barrack-like and utilitarian buildings of recent years. The gaily painted houses, the golden domes and the green and blue and red spires give it a picturesque and semi-Oriental appearance, which is emphasised by the great variety of nationalities, often indicated by their special costumes amongst which Asiatic peoples are well represented. The crowds of beggars and homeless waifs add to the impression. A last strange addition to the contrasts of Holy Mother Moscow is the preservation by the Soviet Government of the ikon of the Iberian Virgin, formerly the most revered of all the ikons, in her chapel shrine, while on a neighbouring wall is the inscription "Religion—opium for the people," put up by the same Government. The illiterate peasant bows and crosses himself to both alike.

The Kremlin.—The citadel, fortress or Acropolis, common to ancient Russian towns and known as the Kremlin, is the centre round which Moscow has grown. It is shaped like an isosceles triangle, one side running parallel with the Moskva river; its huge pyramidal walls of pale pink brick are surmounted by battlements, and pierced by five gates. The Borovitzkiye gate (1490) (bor-wood) is situated on the spot where, in the midst of a dense wood near the mouth of the Neglinka tributary of the Moskva, the first settlement arose on the Kremlin hill. The Neglinka, whose swampy banks formerly added to the safety of the fortress, now runs underground. The Taynitzkiye gate, first erected in 1498, but destroyed by Catherine II. and rebuilt at a later date, had a secret passage (taynik) connecting it with the river. The Spasskiye Vorota (Gate of Salvation) (1491) is the main entrance

(1) BY COURTESY OF THE FRIENDS OF SOVIET RUSSIA

THE KREMLIN AND THE RED SQUARE IN MOSCOW

1. The Kremlin, an old fort which was for many centuries the centre of Russia's political and religious life. It contained within its walls the tsar's palace, great churches, and palaces of the nobility

2. The Red Square, looking toward the Iberian Gate, with the Spassky Gate and Lenin's Mausoleum on the left. The demonstration is by competitors in the 1928 games (Spartakiad)

and opens on to the Red Square. Before the 1917 revolution every passer-by was compelled to uncover to the frescoes representing the Redeemer. In 1625 an Englishman erected the famous peal of bells in the tower above the gate, from which the "International" is now pealed at 12 o'clock and 6 o'clock, and the Russian Revolutionary Funeral March at 3 o'clock and 9 o'clock. These gates, with drawbridges, converted the Kremlin into an island fortress when the bells of the alarm tower gave warning of an approaching Tatar raid. The oaken 12th century walls remained until 1485–95, when the present stronger and more fire-resisting walls were erected. The stone walls formerly surrounding the Kremlin and the Kitai Gorod on the west, north and north-east, were destroyed in the 18th century and replaced by boulevards, and broad streets with gardens on either side have replaced the outer earthen walls and palisades.

An irregular enclosure made in the reign of Catherine II. encloses the outer parts of the city, though the suburbs have extended far beyond it. In the 17th century the Kremlin lost its importance as a fortress and ornamental tent-shaped additions were made to the towers. The tsars and the patriarchs of the Greek Church resided within the Kremlin until the reign of Peter the Great, when the court was removed to St. Petersburg (Leningrad). In the 18th and early 19th centuries it fell into disrepair and many monuments of mediaeval Russian architecture were lost. The arsenal in the Kremlin was held by the pupils of the higher military schools against the Bolshevists in the 1917 revolution and the bombardment carried out by the latter damaged many parts of the Kremlin; the damage has been repaired as far as possible. The Kremlin can now be entered only by special permission of the commandant. Within it along the only street, re-named Communist street, are the residences of former court officials, within which the Kremlin Command and the more important Government officials of the Soviet Union are now housed. In the former Moscow Senate (1775–84) are held the meetings of the All Russian Central Executive, the Central Executive Committee of the Union and the Councils of the People's Commissars (Sovnarkom). In this street are the Poteshny Dvoretz (Pleasure Palace) 1650–51, a lofty green building, now undergoing restoration, the exterior of which has retained its 17th century appearance; the Orujeynaya Palata (1849–51), built in pseudo-Russian style and organized as a museum of the decorative arts (1920–24) to which the more important treasures of tapestry, enamel, jewelled and silver work from the cathedrals and monasteries of Moscow and from the treasury of the patriarch of the Greek Church have been removed; and the Great Kremlin palace (1838–49), a building in white stone with a gilded cupola. Various congresses, including that of the Communist International are held in the former palace throne room. Within the palace are the *terems,* rooms erected in the 17th century by Tsar Michael Feodorovitch for his sons and restored in 1836–49. Another wing of the palace, the Granovitaya Palata (1473–90), consists of a single-vaulted apartment, a state reception room where Ivan the Terrible in 1552 celebrated the conquest of Kazan. Its painted frescoes were destroyed in 1612 during the Polish occupation.

Cathedrals, Churches, etc.—To the east of the Great Kremlin Palace is the cathedral square, surrounded by ancient churches. The cathedral of the Annunciation (Blagovyeschenskiy) with its nine cupolas, was erected by architects from Pskov (1484–89) on the site of an old church first built in 1397. The sacred pictures of Rublev (1405), on the ikonostas of the high altar, have been preserved. The Archangel cathedral was designed by a Milanese architect and built in 1505–09 on the site of the original 14th century cathedral. It contains the tombs of the tsars, from Ivan Kalita (1340) to Ivan Alexeivich (1696), with the exception of Boris Godunov, whose body was removed in 1606 to the Troitza-Sergievskaya Lavra. Of the later tsars only Peter II. is buried here. In 1920–21 the cathedral was restored, and many additions of later centuries were removed. The cathedral of the Assumption (Uspenskiy Sobor) 1475–79, was designed by a Bolognese architect, on the site of the ancient church of the Assumption (1325), which fell to ruins in 1472. It is in the Lombardo-Byzantine style, with Indian cupolas, and its Italian innovations are minutely described in the chronicles and were frequently copied in later Russian architecture. From the 16th century onwards it was the coronation church of the tsars. The frescoes were restored and covered with new paintings for each occasion, and the work of a commission appointed in 1912 was interrupted by the revolution, so that frescoes in various stages now appear in a partially restored condition. Near the south porch stands the carved walnut throne of Ivan the Terrible, with a low relief illustrating the presentation of the insignia of the Imperial power sent to Vladimir Monomach by the emperor of Byzantium.

The Polozhenia Ris (Ordination of priests) cathedral was built in 1484–86, by Pskov craftsmen, and has a beautiful porch with terra cotta columns. A fantastic group of 11 small domes is formed from the cupolas of the church of "The Redeemer Behind the Golden Rails" (1635–36), the church of the Crucifixion (1681) and the church of the Resurrection. The palace of the patriarch (1655–56), like the neighbouring cathedral of the Twelve Apostles, was converted, after the abolition of the patriarchate in the mid-eighteenth century, into dwellings for the monks. In 1918 restorations were begun and are still in progress. Opposite to the Uspenskiy cathedral rises the lofty bell tower of Ivan the Great, one of the public works undertaken by Boris Godunov in 1600 to relieve the famine-stricken population. To the east of it are two other belfries, one, erected by the Italian architect Petroche (1532–43), harbours the chief churchbell of Moscow, whose first stroke at midnight on Easter eve sets the bells of the other 350 churches of Moscow ringing, the other dating from 1624. These two belfries were damaged during the French invasion of 1812, but that of Ivan the Great escaped. Near it stands the Tsar Kolokol, the largest bell in the world, recast in 1735. During the fire of 1737 a piece of the bell broke off, and the bell itself, not yet hung, fell to the ground.

Near the Spasskaya Gate is the former Vosnesensky nunnery (1389–93), restored in the 19th century, the burial place of the wives and sisters of the tsars. The church of St. Michael Malein, with its 15th century interior stone relief, has been converted into a museum of old Russian sculpture. The 18th century Little or Nicholas palace is now used as a club by the Kremlin military school. The Chudov (Miracle) 14th century monastery, rebuilt in 1771, was formerly the residence of the metropolitans of Moscow, and a State prison. Restorations undertaken in 1924 revealed ancient corridors and rooms, and the building is now a museum for the objects of art from the famous Solovetzky monastery on the White sea, evacuated during the civil war following the 1917 revolution. In the monastery courtyard stands the cathedral of the Miracle of the Archangel Michael (1501), an interesting combination of the Vladimir-Suzdal and Italian styles. Opposite the Chudov monastery are the beautifully wrought ornamental Tsar Cannon (1586) and several other ornamented cannons. The now unsightly 19th century barracks, the training school for officers of the Red army, once had a beautiful façade in the classical style later removed by order of the tsar Nicholas who considered it unsuitable to a barracks. The Kremlin arsenal was the main store house for ammunition in Moscow until 1917 and this enabled the officers of the Old army to hold out against the Bolsheviks for some time and resulted in a damaging bombardment of the Kremlin.

The Kitai Gorod.—The Kremlin was the former residence of the aristocracy, and to the east of it lies the Kitai Gorod, formerly the residence of the merchants. It is surrounded by a wall constructed in 1534–38, and next to the Kremlin, is the most ancient part of Moscow, as its narrow, irregular lanes indicate. Kitai (Chinese), is supposed to be derived from the Tatar word for fortress. Since the 1917 revolution, the great Trusts, the People's Commissariats and other Government Offices have been located here and the number of inhabitants is small, four-fifths of it being occupied by offices, an indication of the growth of bureaucracy. The Red Square, a kilometre in length and 130 metres broad, has the Kremlin wall on one side, with arcades now housing Soviet trade enterprises and the administrative offices of the Red army, opposite to it, and Lenin's Mausoleum on another, and the fantastic Pokrovsky or Vasili cathedral opposite to it. The latter,

with its many coloured towers, was begun by Ivan the Terrible in 1554 to commemorate the conquest of Kazan, but not completed till 1679. It was used as a stable by the French cavalry in 1812, but restored in 1839–45; it was converted into a Museum (1921–24) by the Soviet Government. The Red Square, with its stone tribunal, formerly the forum, market-cross and place of execution, has always been the centre of political life.

Here, beneath the Kremlin ramparts, many fierce fights with Tatar raiders took place in the middle ages. In the 17th century an insurrection was crushed and the rebels executed in the square. The great trade routes from old Novgorod, Tver, the East and the Ordynka, or route from the Tatar Golden Horde converged on the Square, at the extreme end of which was the landing-place from the Moskva river, so that in times of peace it was a great market. It was the scene of a great demonstration during the 1905 revolution, when the calling of the Duma, or national council, was extorted from the tsar. In Oct. 1917 fierce fighting took place between the Bolsheviks and the White army, and through it afterwards passed the two great funeral processions of the victims of this civil strife. Since then workers' demonstrations and military parades have been regularly organized.

Near the Kremlin walls are "The Graves of the Brothers," the five hundred Bolshevik men and women who lost their lives in the 1917 revolution. In front of the graves stands the Lenin Mausoleum, a strange wooden structure, painted red, within which lies the embalmed body of Lenin, and to which long queues of worshippers throng, while other worshippers, quite close to them, throng to pay homage at the Shrine of the Iberian Virgin. Opposite the mausoleum, which is to be replaced later by a stone structure, is a monument to the butcher from Nizhni-Novgorod who organized the troops that drove the Poles out of Moscow in 1612. At the northern entrance to the Red Square stands the State historical museum, built in 1883 on the site of the former Moscow university; to it were brought after the 1917 revolution the library and rare manuscripts of the Holy Synod, and a Dostoievsky section was added. Facing the historical museum is the 17th century Kazan cathedral, a memorial of the deliverance of Moscow from the Poles. Among numerous other beautiful examples of architecture are the lovely Praise of the Holy Virgin church (1707), the New Maiden's convent (1524), converted into a museum in 1924, and the church of Gregori Novokessariysky (1668–79).

Museums and Theatres.—The city has numerous museums, of which the most famous is the State Tretyakov gallery (1892), reorganized in 1918 and enriched by some thousands of works of art taken from private collections and nationalized. The former Rumyantsev museum was dissolved in 1924, the works of western painters being transferred to the Museum of fine arts and those of Russian painters to the Tretyakov gallery.

Of the 18 theatres of Moscow the most famous are the Moscow art theatre and the Meyerhold theatre; in the latter there are no wings, no scenery, no footlights and no drop-scene; word or gesture, aided by wooden screens and simple mechanical contrivances, are the only methods of presentation. Its educational institutions include the Moscow State University, the Institute of Oriental Studies, the Academy of Fine Arts, Agricultural, Mining and Technical Schools, various Communist institutions, and some well-equipped schools, including experimental schools. There are schools attached to many factories, both for young workers and for adult illiterates. There are also several children's homes for the unfortunate orphan waifs, the legacy of the years of war, famine and social disorganization. Of the numerous organizations, clubs and societies, the most famous is the Executive Committee of the Third International (Comintern), and others of note are the All Russian Association of Anarchists and Anarchist Communists, the Red International of Labour Unions (Profintern), the International Council of Peasants, the Central Union of the Co-operatives (Centrosoyus), the Communist Youth Association (Comsomol), various clubs for national minorities, the Central Peasants' home and the Children's club.

History.—From its foundation in the 12th century until the end of the 13th century, Moscow remained a dependency of the princes of Vladimir, and was burned and plundered by the Tatars in 1237 and 1293. Under Daniel, son of Alexander Nevsky (1261–1302), the prince of Moscow acquired importance from his wars against Lithuania, and annexed Kolomna at the confluence of the Moskva and Oka. In 1300 the Kremlin was enclosed by a strong earthen and timber wall and a policy of annexation by various means was consistently carried out by Daniel's successors. Under Ivan Kalita (1325–41) the principality of Vladimir was incorporated with that of Moscow. In 1367 the Kremlin was enclosed by stone walls and the town successfully resisted Lithuanian attacks under Olgierd (1368 and 1371). Kalita's grandson, Dmitry Donskoi, annexed Starodub and old Rostov, and took part in an attack on the Mongols at Kulikovo on the Don (1380). In 1382, Moscow was for the last time captured and plundered by the khan of the Golden Horde. By the end of the 15th century Moscow had annexed most of the surrounding districts, though it was not until the reign of Ivan III. (1462–1505) that the prince of Moscow claimed to be "Ruler of All Russia." Ivan IV. (1533–1584) annexed Novgorod and Pskov and subdued Kazan and Astrakhan, but many disasters fell on Moscow at this time. In 1547 two conflagrations destroyed the greater part of the city and the Tatar khan of the Crimea advanced against it, but had to withdraw. In 1571 he captured Moscow and burned all the city outside the Kremlin; the annals record that of its 200,000 inhabitants only 30,000 remained. In 1591 the Tatars of the Crimea again attacked the city outside the Kremlin.

During the latter half of the 16th and the whole of the 17th century, Moscow was the scene of much disorder and internal strife. Revolts against the favourites of the tsars were crushed with merciless ferocity with the aid of the *streltzy,* a class of citizens and merchants rendering hereditary military service to the tsar. The spread of the *raskol* or nonconformist movement and the news of the rebellion of Stenka Razin led to further severe repressive measures. In 1698 the *streltzy* themselves revolted and were suppressed only after fearful slaughter by Peter the Great. In 1703 Peter, wearied of the opposition to his plans of reform, of the conspiracies of the *boyars* and of the distrust of the masses, founded the new capital of St. Petersburg (Leningrad), and Moscow declined for a time. Conflagrations in 1739, 1748 and 1753 caused much misery, but led to the enlarging of the streets and squares. Under Catherine II. some new buildings, the Senate House, the Foundling and other hospitals and the salt stores were built and revival began. In 1812 came the disaster of the Napoleonic invasion. The Russian troops evacuated Moscow on Sept. 13, six days after the battle of Borodino (*q.v.*) and next day the French occupied the Kremlin. That night the capital was set on fire through the carelessness of its inhabitants and the stores in the bazaar were destroyed. The inhabitants abandoned the city, which was given up to plundering by troops of both armies. The burning of the city, however, was the signal for a general rising of the peasants against the French. The want of supplies, the impossibility of wintering in a ruined city continually attacked by Cossacks and peasants, compelled Napoleon to leave Moscow on Oct. 19, after an unsuccessful attempt to blow up part of the Kremlin. After a few years of desolation, the city was rebuilt in the Russian "Empire" style.

In the second half of the 19th century, following on the abolition of serfdom and the development of railroads and industries, Moscow grew rapidly. Many large factories arose on the banks of the Moskva, and the workmen settled in the Khamovniki district, once the abode of the serf weavers and the serfs of several monasteries. This rapid development of the proletariat in poor conditions of housing and labour, with no legitimate means of redressing grievances, led to a growing feeling of discontent and the outbreak of 1905 was only suppressed after a fortnight's hard fighting. After the October 1917 revolution fierce fighting again broke out, but the Bolshevists ultimately triumphed. Between 1917 and 1920, great hardships were endured by the population owing to the difficulties of food and fuel supply; winter conditions of semi-starvation and lack of warmth were severe, and the population diminished from 2,000,000 in 1917 to 800,000 in 1920, in spite of the transference to Moscow of the administrative centre.

In 1918 there were social revolutionary and anarchist risings. The terrible famine year 1920–21 added to the difficulties of provisioning the city, as did the attempts to dispense with the use of money. After the introduction of the new economic policy, more normal conditions began to return.

In 1923 electrification schemes were inaugurated to decrease the fuel famine (*see* Moscow, province), and a great influx of population again began. But during the famine period many wooden houses had been destroyed for use as fuel, for which purpose too, much of the wooden pavements had been removed. No repairs had been carried out and building had ceased. Thus a serious and dangerous situation was created, not only by the lack of housing accommodation, but by the difficulty of supplying food to so vast a population. Repairs and building construction began in 1923, but the short building season hampers progress and it must be many years before living conditions in Moscow approach the normal. The supply of food, though better, is still inadequate and food queues are common. Overcrowding has most disastrous results in the case of infants, and in order to meet this aspect, the Soviet government has nationalised some former palaces and turned them into crêches for babies, and many factories also have crêches attached where mothers may leave the children during the day. This does not, however, avoid the perhaps as serious stunting moral and physical results of overcrowding at a later stage and large building plans have been sketched by the housing commissions, though lack of capital hampers them.

MOSCOW, a city of northern Idaho, U.S.A., 90 m. S. by E. of Spokane, near the Washington State line, on Paradise creek, at an altitude of 2,578 ft.; the county seat of Latah county and the seat of the University of Idaho. It is on Federal highway 95, and is served by the Great Northern, the Northern Pacific and the Union Pacific railways. The population in 1920 was 3,956 of which 90 per cent was native white; in 1930 the population had grown to 4,476 according to the Federal census. The city is a trading and distributing centre for a rich non-irrigated region (part of the "Palouse country"), producing chiefly grain, live stock and fruit. It has a large flour mill and meat-packing plant, creameries and other manufacturing industries. The university (established 1889) has a beautiful situation on high ground southwest of the city. A southern branch is maintained at Pocatello. Its campus and farm at Moscow cover 600 ac.; its College of Agriculture maintains experimental sub-stations at Caldwell (320 ac.), Sandpoint (170 ac.) and Aberdeen (80 ac.) and one of 180 ac. at Felt, for experiments in dry farming and irrigation at high altitude; its School of Forestry has an experimental tract and field laboratory of 640 ac. on Moscow mountain, 6 m. N. of the campus. The State Bureau of Mines and Geology has its headquarters at the university. Moscow was settled about 1870 and incorporated in 1887.

MOSCOW NARODNY BANK, LTD. The original Moscow Narodny Bank (*i.e.*, People's Bank) was the bank of the Russian Co-operative Movement before the Revolution. It first established an agency in London in 1916. In 1919 this was transformed into an English Company under the title of the Moscow Narodny Bank Ltd. with a paid up capital of £250,000. Subsequent issues of capital have brought the authorized amount to £1,000,000 sterling, of which £750,000 is now paid up. In addition, the reserve funds of the bank amount to £115,000. The shares of the bank are held exclusively by co-operative organisations in the U.S.S.R. The largest shareholders are the two leading co-operative banks, *i.e.*, the All-Russian Co-operative Bank (*Vsecobank*) and the All-Ukrainian Bank (*Ukrainbank*) holding between them 73% of the shares; Centrosoyus, representing the Consumers Co-operative Movement, holds 12·5% of the shares, and the Agricultural Co-operative Societies (Selosoyus), holding 12·5%. Smaller Co-operative Societies account for the 2% balance of the shares.

The balance sheet figures show the speed at which the Bank has developed its operations. The assets of the Bank on December 15, 1919, totalled £633,522, and on July 1, 1928, they amounted to £7,287,550. In the year 1920 the turnover was approximately £19,000,000. In the first ten months of 1928 it exceeded £220,000,000.

The principal purpose of the Moscow Narodny Bank is to finance the export and import operations of the Central Co-operative organisations in the U.S.S.R. trading on foreign markets. Besides performing the usual banking operations the Bank acts as a medium through which credits may flow to the co-operative organizations for financing their foreign trade. Such credits take the form of advances against goods in the course of export or stored abroad or in course of import into Russia, as well as the discounting of bills for the payment of purchases made abroad. The bank also assists co-operative organizations in financing the collection of raw materials for export, partly from its own resources and partly by discounting or rediscounting or guaranteeing bills drawn by the exporting co-operative organizations.

It is mainly concerned with the export of agricultural produce, *i.e.* dairy produce, butter, eggs, cheese, etc., furs, flax, hemp, tow, bristles, horse-hair, poultry, tobacco, skins and hides. The imports into Russia in which it is chiefly concerned are tea, wool, agricultural machinery and implements, and tools of various kinds.

In addition to its offices in London the bank has offices in Paris, Berlin and a representative in New York. It holds a controlling interest in the Co-operative Transit Bank in Riga, through which Russian operations in Latvia are financed. It acts as the centre abroad through which the Russian co-operative organizations are brought into banking contact with leading banks in London, New York, Berlin, Hamburg, Paris, Belgium, Holland, Switzerland and Canada. It is naturally giving special attention to the development of its relations with the co-operative and labour banks in England, France, Germany, Belgium and Switzerland and with the labour banks in America. Though its share-holders are Russians, it is an English company subject in all respects to English law; its chief offices are in London, and its main operations are carried on in sterling in accordance with British banking practice. (N. Ba.)

MOSELEY, HENRY GWYN-JEFFREYS (1887–1915), British physicist, was educated at Eton and Trinity College, Oxford. As lecturer in physics in Rutherford's laboratory at Manchester university, then as John Harling fellow, and subsequently at Oxford, he worked first on radioactivity and finally he carried out a brilliant series of researches proving the existence of a simple relationship between the X-ray spectrum of an element and its atomic number (*q.v.*), thus establishing a new and valuable method of chemical analysis and solving the outstanding problems of atomic structure and spectral lines (*see* Spectroscopy and X-ray). He was killed in Gallipoli on Aug. 10, 1915.

MOSELEY NUMBER, an alternative name for atomic number (*q.v.*), owing to the fact that the first direct experimental evidence for the allocation of atomic numbers to elements was provided in 1913 by H. G. J. Moseley (killed in action, 1915).

MOSELLE, a department of north-eastern France, formed of the portion of Lorraine which was annexed by Germany as the result of the war of 1870. Area, 2,403 sq. miles. Pop. (1926), 633,461. It is bounded on the north and north-east by Luxembourg and Germany, including the Saar territory, on the east and south-east by the department of Bas-Rhin, and on the south, south-west and west by the department of Meurthe-et-Moselle. The department is largely floored by Triassic rocks, which form a surface, for the most part, between 600 and 1,000 ft. above sea-level, and are drained by the Moselle and its feeders, and it has a number of small lakes towards the east. Across the German border, south-east of the Moselle, stand the heights of The Hunsrück and the Palatinate, but the valley of the Moselle and the passes of Saverne and Haguenau across to the Rhine valley have made this area a double gateway between Germany and France, and it has long been in spirit a frontier province of the latter. The average winter temperature, reduced to sea-level, is below 35·5°, the average summer temperature is above 66°, thus giving conditions not very different from those of the Vosges. Being almost surrounded by higher land, the department has a rainfall for the most part below 30 in. per annum. Moselle is a region in which, partly because it has taken great effort to transform the soil, and partly because wars have retarded social change, the traditional system of concentrated villages and

infinite subdivision of strips has persisted. The valley of the Moselle in the region of Metz is famous for its vineyards. There are very important mines of coal and iron in the department, and famous salt deposits. The chief industries are salt-working, metal-founding, lime-burning and cement-making, and the manufacture of glass, crystal, pottery and porcelain (Sarreguemines), machinery, chemical products, textiles, paper, wooden objects, preserved foods, brushes, boots and shoes, pipes and leather goods. There are nine arrondissements (Metz-urbain, the capital, Metz-rural, Boulay, Château-Salins, Forbach, Sarrebourg, Sarreguemines, Thionville-east and Thionville-west), 36 cantons and 763 communes. The department forms part of the VIth. and XXXVth. military regions, and Metz is the seat of a bishopric.

MOSELLE (Ger. *Mosel*), a river of France and Germany, 314 m. long, a left-bank tributary of the Rhine. It rises on the west flank of the Vosges, near the Col. de Bussang. It first flows north-west, crossing the Hercynian gneisses, turns north at Remiremont, passes off the gneisses at Épinal to cross the Trias and Jurassic rocks. From Toul past Nancy, Metz and to Diedenhofen it flows along a subsequent valley, after which it turns north-eastward to cross the Trias and Devonian rocks and join the Rhine at Coblenz. It leaves France below Diedenhofen, for a short distance forms the frontier between Germany and Luxembourg, and then enters Germany. The chief tributaries are the Moselotte, Meurthe, Seille and Saar on the right, and the Madon, Orne and Sauer on the left. Navigation for small vessels extends downwards from Fronard, a little below Nancy. The river meanders about in its lower valley, where are the vineyards from which the well-known Moselle wines are produced. (*See* RHINE.)

MOSELLE LINE, the designation of a line of French barrier forts on the upper Moselle between the fortresses of Épinal and Belfort (*see* these articles, also MEUSE LINE). This line, the separate forts of which commanded the relatively few lines of advance from upper Alsace through the Vosges, had for its purpose, in French policy and strategy prior to the World War, the deflection of a possible German invasion from Alsace towards Belfort, or towards the open gap between Épinal and Toul called the Trouée de Charmes, where it could be nipped in flank by a prearranged counter-stroke.

MOSELLE WINES. The vineyards of the Moselle are of greater antiquity than those of the Rhine; they were originally planted by the Romans at a time when the Rhine was the boundary of the Roman empire. It is only from Treves to Coblenz that the vineyards of the Moselle produce white wines of truly great distinction, exceptionally fine bouquet and sufficient merit to command abroad much higher prices than local consumers are willing or able to pay.

Under the name of Moselle are included not only the wines from the vineyards on both banks of the Moselle from Treves to Coblenz, but also those from the vineyards of the Saar and Ruwer, two tributaries of the Moselle. The Saar joins the Moselle a few miles above Treves; its finest vineyards are those of *Scharzhofberg, Bockstein, Geisberg* and *Euchariusberg;* very fine wines are also made at *Scharzberg, Agritiusberg, Wiltingen* and *Oberemmel.*

In the valley of the Ruwer, a small river which joins the Moselle below Treves, some very delicate and fascinating white wines are made, none better nor better known than those from the ancient ecclesiastical vineyards at *Grunhaus.* From there to Coblenz, upon either bank of the Moselle, are grown the finest wines of the Moselle proper. To name but a few: *Piesport* and *Braunberg,* on the left bank of the river, *Berncastel,* further north, on the opposite bank, and from thence northwards the vineyards of *Graach, Wehlen, Zeltingen* and *Trarbach,* on the right, and those of *Erden, Machern* and *Urzig,* on the left, are among those which produce the most delicate Moselles, wines which are light, pleasantly dry, and possessing a "bouquet" which is as distinctive as it is charming.

MOSER, JOHANN JAKOB (1701–1785), German jurist, was born at Stuttgart on Jan. 18, 1701. He studied at the University of Tübingen, where, at 19, he was appointed extraordinary professor of law. He moved to Frankfort-on-the-Oder in 1736, but resigned on account of differences with the king of Prussia. In 1751 he was recalled to Württemberg as district counsellor, and in 1759 was imprisoned at Hohentwiel on account of the steps he had taken in connection with this office against certain tyrannical proceedings of the duke. In 1764 he was released and was restored to office. He died on Sept. 30, 1785. Moser was the first to discuss in an adequate form the subject of European international law. He wrote more than 500 volumes, his principal works being *Deutsches Staatsrecht* (1737–54), *Neues deutsches Staatsrecht* (1766–75), *Deutsches Staatsarchiv* (1751–57), *Grundriss der heutigen Staatsverfassung von Deutschland* (1754).

See Schmid, *Das Leben J. J. Mosers* (1868); Schulze, *J. J. Moser, der Vater des deutschen Staatsrechts* (1869).

MÖSER, JUSTUS (1720–1794), German publicist and statesman, was born on Dec. 14, 1720, at Osnabrück, where he became *advocatus patriae* (state attorney), and held other important legal appointments. He died at Osnabrück on Jan. 8, 1794. Möser's ideas on history and economics exercised considerable influence on Herder and Goethe. His principal works were *Osnabrücks Geschichte* (2 vols., 1768); *Patriotische Phantasien* (1775–86; new ed. by R. Zöllner, 1871), in which he pleaded for a national organic development of a state in the place of arbitrary laws imposed by the sovereign.

See his *Sämtliche Werke,* ed. B. R. Abeken (10 vols., 1842–44); also J. Kreyssig, *Justus Möser* (1857); L. Rupprecht, *Justus Mösers soziale und volkswirtschaftliche Anschauungen* (1892); K. Mollenhauer, *Mösers Anteil an der Wiederbelebung des deutschen Geistes* (1896).

MOSES (Gr. Μωυσῆς, Μωσῆς), the great Jewish lawgiver, prophet and mediator, and leader of the Israelites from Egypt to the eastern borders of the promised land. The records of his life and work are noticed in the articles EXODUS, NUMBERS, DEUTERONOMY, where the several sources of the narratives are described. He appears in Midian at the "Mount of God" (Horeb) dwelling with its priest Jethro (*q.v.*), one of whose seven daughters he married, thus becoming the father of Gershom and Eliezer. Of his earlier life it was said that he was born in Egypt of Levite parents, and when the Pharaoh commanded that every new-born male child of the Hebrews should be killed, he was put into a chest and cast upon the Nile. He was found by Pharaoh's daughter, and his (step-)sister Miriam contrived that he should be nursed by his mother; on growing up he killed an Egyptian who was oppressing an Israelite, and this becoming known, he sought refuge in flight.

At the holy mount, Moses received the divine revelation, and was commissioned to bring the people a three-days' journey out of Egypt to sacrifice at this spot (Exod. iiii. 12, 18; v. 3, viii. 27). The deity revealed himself in a new name, Yahweh, and with signs and wonders fortified Moses for his task. On his return he experienced a remarkable incident which is obscurely associated with the rite of circumcision. The plagues with which the reluctant Pharaoh was coerced culminated in the destruction of all the first-born, and Israel escaped to the Red Sea. The pursuing Egyptians were drowned and the miraculous preservation of the chosen people at the critical moment marks the first stage in the national history (*see* EXODUS, THE).

The other events need not be detailed. Kadesh (holy) was the chief centre. This was the scene of the "strife" at Meribah (striving) where Yahweh "shewed himself holy" (Num. xx. 1–13); a parallel account joins the name with Massah (trial, proof) where Yahweh "proved" the people (Exod. xvii. 1–7). These two names (Deut. ix. 22, xxxii. 51) with their significant meanings recur with varying nuances (Ps. lxxxi. 7, xcv. 8 *seq.*). Here also in the wilderness of Shur, and possibly at En-mishpat (well of judgment, *i.e.,* Kadesh, Gen. xiv. 7), Yahweh made for Israel "statute and judgment" and "proved them." This is apparently viewed as the goal of the three-days' journey (Exod. xv. 22–25). In this district the defeat of the Amalekites is more naturally located (Exod. xvii.; *cf.* I Sam. xxvii. 8) and here, finally, for some

MOHAMMEDAN MOSQUES

1. The Mosque of Sultan Ahmed, Constantinople, 17th century, characteristically Turkish in its development of Byzantine dome forms
2. The Jumma Musjid (Great Mosque), Delhi, India, built by Shah Jahan in the 17th century, showing typical Mogul lavishness in its use of coloured marbles
3. The Mosque at Samarra in 'Iraq showing characteristic Persian simplicity of surfaces with polychrome faience tile decoration
4. The Court of the Mosque of Ibn Tulun, in Cairo, begun in 878, an almost perfect example of the early Syrian-Arabic-Egyptian arcaded mosque
5. The Mosque of Omar (Kubbet-es-Sakhra) at Jerusalem, begun in 643, an early Muslim variant of Byzantine forms
6. The Mosque of Sultan Abdul Medjid at Ortakeui, near Constantinople, showing the mixture of European and Mohammedan forms which was general in Turkish 19th century architecture
7. The Moti Musjid, Lucknow, India

cause, now obscured, Moses and his brother Aaron (*q.v.*) incurred Yahweh's displeasure (Num. xx. 12, xxvii. 14; Deut. xxxii. 51; Ps. cvi. 3). Pisgah or Mt. Nebo (the name suggests a foreign god), to the north-east of the Dead Sea became the scene of the death of Moses; his burial-place was never known (Deut. xxxiv.).

Close study of the Pentateuch, in connection with the political and religious history of Israel as presented to us in other parts of the Old Testament, makes it difficult if not impossible to accept the tradition which ascribed to Moses every detail of Israel's legal and cultural institutions. It was inevitable that these should be traced back to the great hero, and there is evidence which suggests that in some quarters other elements in Israelite life, repudiated by the orthodox Jew, were once attributed to him. The snake worship of Jerusalem was thus assigned to him, and it is at least possible that at one time he was held to be the author of the bull worship of Bethel and Dan (II Ki. xviii. 4).

Beyond question Moses must be regarded as the founder alike of Israel's nationality and of Israel's religion. His leadership in the Exodus and his prominence in the great covenant at Sinai (or Horeb) are hardly to be doubted. It was he who welded into one people the various kindred tribes under his leadership, and it was he who introduced Israel to Yahweh and Yahweh to Israel. But further details must be a matter of conjecture. Even the earliest code of laws in the Bible (Ex. xxi.–xxiii.) is simply a local and national form of the civil law common to Babylonia, Assyria and the Hittites, and (since it presupposes an agricultural community) was probably adopted by Israel after the settlement in Canaan. The familiar Decalogue (Ex. xx. 1–17) is sometimes attributed to Moses in its earliest form, but all we can say with certainty is that it probably represents the ethical principles he laid down. Yet, with all this doubt, the fact remains that Moses stands out as one of the greatest figures in history.

(S. A. C.; T. H. R.)

MOSES, ASSUMPTION OF, an extra-canonical apocalyptic work of the Old Testament. (*See* Apocalyptic Literature.) It is a prophecy of the future relating to Israel, put into the mouth of Moses, and addressed to Joshua just before the great lawgiver died. Founded upon the book of Deuteronomy, it contains a brief history of Israel from Moses to the Messianic age. The most striking feature in this work is the writer's scathing condemnation of the priesthood before, during, and after the Maccabean period, and an unsparing depreciation of the Temple services.

The book has been assigned to most dates between the death of Herod the Great and that of Bar-Cochba; but the true date appears to lie between 4 B.C. and A.D. 30. Herod is already dead (vi. 6), hence it is after 4 B.C.; and Herod's sons are to rule for shorter periods than their father, hence it must have been composed before these princes had reigned thirty-four years—*i.e.*, before A.D. 30. But there are grounds for assuming that A.D. 7 is probably the earlier limit.

The author was not an Essene, for he recognizes animal sacrifices and cherishes the Messianic hope. He was not a Sadducee, for he looks forward to the establishment of the Messianic Kingdom (x.). Nor yet was he a Zealot, for the quietistic ideal is upheld (ix.), and the kingdom is established by God Himself (x.). He was clearly a Pharisaic Quietist, a Pharisee of a fast disappearing type, recalling in all respects the *Chasid* of the early Maccabean times, and upholding the old traditions of quietude and resignation. His object is to protest against the growing secularization of the Pharisaic party through its adoption of popular Messianic beliefs and political ideals. But his appeal was in vain, and so the secularization of the Pharisaic movement culminated in due course in the fall of Jerusalem.

Bibliography.—*See* the edition by R. H. Charles (1897), and his article in *Apocrypha and Pseudepigrapha of the Old Testament* (ed. Charles, 1913), vol. ii., where full bibliographies are given.

(R. H. Ch.)

MOSETENAN, an independent linguistic stock of South American Indians, whose name is derived from the Mosetenes, one of its most important tribes. They live in northern Bolivia along the Beni river and east of it, approximately between 15° and 16° S. Lat. They are rather light in skin colour. They are a sedentary and largely agricultural folk, living in reed and thatch huts, and wear brilliantly coloured cotton sleeveless home made tunics. They do not use canoes, but make rafts. The bow is their main weapon. Little or nothing is known of their original culture.

See R. Schuller, in B. Biboloti, *Moseteno Vocabulary and Treatises* (Northwestern University, Chicago, 1917); A. D'Orbigny, *L'Homme Americain* (Paris, 1839).

MOSHEIM, JOHANN LORENZ VON (1693–1755), German Lutheran divine and Church historian, was born at Lübeck on Oct. 9, 1693. He studied at Kiel, and became professor at Helmstädt in 1723. His *Institutionum historiae ecclesiasticae libri IV.* (1726), established his reputation. Mosheim was consulted by the authorities when the new university of Göttingen was being formed; and in 1747 was made chancellor of the university. He died at Göttingen on Sept. 9.

See C. Heussi, *Johann Lorenz von Mosheim* (1906).

MOSLER, HENRY (1841–1920), American artist, was born in New York city on June 6, 1841. In 1863 he went to Düsseldorf, where for almost three years he was at the royal academy schools; he subsequently went to Paris, where he studied for a short time under Ernest Hébert. His "Le Retour," from the Paris salon of 1879, was the first American picture ever bought for the Luxembourg. He received a silver medal in Paris 1889, gold medals at Paris 1888 and Vienna 1893. Examples of his work are in the Sydney art museum, N.S.W., and the art museums of Springfield, Mass., Cincinnati, O., and New York. He died in New York on April 21, 1920. His son, Gustave Henry Mosler (1875–1906), a pupil of his father and of Léon Bonnat, exhibited at the salon in Paris, receiving a medal for his "De Profundis."

MOSLEY, SIR OSWALD ERNALD, 6th Bart (1896–), British statesman, was born on Nov. 16, 1896, and succeeded his father in 1928. He married in 1920 Lady Cynthia Curzon, daughter of Marquess Curzon of Kedleston. Educated at Winchester he served with the 16th Lancers and in the Flying Corps during the World War. He entered the House of Commons in 1918 as Conservative member for the Harrow division. In the election of 1922 he stood as an Independent, and in the 1924 parliament he sat as a Labour member. Mosley was an active worker in the Independent Labour Party, and was in MacDonald's cabinet of 1929 as Chancellor of the Duchy of Lancaster, but resigned the post in 1930. Lady Cynthia Mosley was elected M.P. for Stoke in the 1929 election.

MOSQUE, a building erected for Mohammedan religious services. The early type of mosque is determined by the position of the Mihrab or prayer niche indicating the direction of Mecca and the ritual custom of having all the worshippers arranged in parallel lines facing in this direction. Thus the Mihrab is placed in the centre of a long wall and accommodations for the lines of worshippers furnished by a series of arcades parallel or perpendicular to the wall in which the Mihrab is placed. The covered portion thus formed is usually a rectangle, wider than it is deep, enclosed by walls at the back and two ends, but open through the final arcade at the front on to a court, frequently surrounded by colonnades, and containing, in its centre, a fountain for ritual ablutions. Beside the Mihrab was placed the Mimbar, or pulpit, which usually consisted of a tall, shrine-like platform against the wall, covered with a pyramidal roof, and approached by a long, straight flight of steps. In later mosques there was also frequently a large raised platform supported on arcades, known as a Dikka, from which portions of the service were read. At Mecca, the first mosque consisted of a series of arcades surrounding a rectangular court in which was the Ka'ba, or sacred rock; obviously no Mihrab was necessary, and the arcades themselves, surrounding the court, formed the prayer hall.

This primitive type of arcaded or colonnaded mosque underwent many changes in various parts of the Mohammedan world. As the Mohammedan builders were peculiarly apt at learning the technique of the peoples whom they conquered, mosque design necessarily absorbed different influences in each country; the influence of Byzantine art was especially strong throughout western Asia. Five differing general schools may be recognized: First,

MOSQUE CALLED YENI-VALIDEH-DJAMI CONSTANTINOPLE

THE MOSQUE AT CORDOVA IS A MOORISH VARIATION OF THE ORIGINAL SIMPLE ARCADED TYPE. THAT AT AGRA SHOWS THE CHARACTERISTIC INDIAN MOGUL DEVELOPMENT OF THIS EARLY FORM. THE MOSQUE OF KAIT BEY OUTSIDE CAIRO SHOWS THE LATER TYPE OF EGYPTIAN MOSQUE WITH VAULTED HALLS AND A DOME. THE THREE TURKISH EXAMPLES SHOW THE SKILLFUL ADAPTATION AND DEVELOPMENT OF BYZANTINE DOME IDEAS WHICH MAKE THE BEST TURKISH MOSQUES MONUMENTAL AND LOGICALLY BEAUTIFUL

the school of Egypt and Syria; second, the school of north Africa and Spain; third, the school of Persia; fourth, the school of the Turkish empire; and last the school of India.

Early Mosques.—It is in the early mosques of the first school that the primitive form appears most completely. The mosque of Amru or Amr (begun 642) and that of Ibn Tulun (878), both in Cairo, and the Great Mosque at Aleppo (978) as well as that of Medina, in Arabia (707), are all remarkably complete examples; those of El-Aksa, at Jerusalem (685) and the great mosque at Damascus (707) are both built with materials taken from Christian churches. The result is necessarily different from the normal type, and the nave, transepts and aisle scheme of a Christian basilica may still be recognized, despite the additional ranges of colonnades and the changes in direction. In both of these, moreover, the Byzantine decorative influence is marked, and especially in El-Aksa, mosaics are used in an entirely Byzantine manner. In the famous Kubbet-es-Sakhra or mosque of Omar (a shrine rather than an ordinary mosque), a purely Byzantine plan, with a circular domed central nave and surrounding octagonal aisles is used. Only the slightly pointed arches differentiate it from a Christian building, and the whole bears witness to the power of Byzantine tradition on early Mohammedan mosques, and is also the earliest example of a dominant dome, which later became a characteristic feature of many mosques.

The mosque of Ibn Tulun, at Cairo, is one of the earliest in which no Byzantine or Roman materials are used; the pointed arch is used throughout and the decoration of the stucco which covers the rough construction already shows that preoccupation with flat surface ornament which is characteristic of later Mohammedan art.

By the time of the Mamelukes a love for more unencumbered interiors, and a growing skill in domical construction had worked

a profound change in Egyptian mosques, and led, as well, to a continually growing richness of exterior treatment, and the use, both outside and in, of much rich stalactite ornament. Moreover, a type of plan, originally used for colleges or medressehs, consisting of four great vaulted halls around a central square court, became usual. The most beautiful example of this is the great mosque of Sultan Hassan at Cairo (1356); even more rich in its decoration, and unusual in its plan, is the mosque of Kait Bey Outside the Walls (1472).

These Egyptian and Syrian mosques furnish excellent examples for tracing the development of the minaret (*q.v.*), the tower from which the call to prayer is given—an integral part of every developed mosque—from the primitive tower of Ibn Tulun, with its outside stair, like that of an Assyrian ziggurat or pyramid temple, to the slenderness and rich balconies of Kait Bey.

Moorish.—The Moorish school of north Africa and Spain, because of its distance from Byzantine centres, preserved the primitive type of mosque plan even longer. The Great Mosque of Kairawan (begun 675) bears many resemblances to those of Amru and Ibn Tulun. It is noteworthy, however, that in the Mihrab, dating from 837, although the capitals are still of quasi-Roman type, the surface decoration already approaches the Moorish type that flowered later in the Alhambra, and that perhaps due to Roman influence domes of considerable size appear at both ends of the central aisle leading to the Mihrab. Equally primitive in its type is the great mosque at Tlemçen (1136); the same type is preserved in many other smaller mosques, such as those of Sfax (prior to the 11th century) and the Great Mosque at Algiers (1018). By far the most important of the Moorish mosques is the Great Mosque at Cordova (begun 780 and much extended in the 10th century), so that the prayer chamber occupied the enormous area of 148,000 sq.ft., with 16 rows of arcades. The whole is decorated with a lavishness unknown in other examples of the style and is noteworthy for the complicated interlacing arches, the doubling of the arcades, the intricate plaster ornament and the frequent use of cusped arches.

Persia.—In Persia, the tradition of Sassanian vault building, and of polychrome, glazed tiles led to mosques of a character entirely different. Thus, although the plan of the great mosque of Isfahan (begun 760, enlarged 1080, repaired in the 16th and 17th centuries) retains the many columned prayer hall or maksoura and the great court of the primitive type, it has a structural grandeur, and an architectural character, totally different, as the centre of each side of the court is occupied by an enormous vaulted chamber opening on the court by a great arch, and instead of the intricate relief ornament there exist large simple surfaces to receive exquisite polychrome tiles. Throughout Persian mosque design domes have an importance not observable in Egypt or Moorish countries, and are frequently of bulbous outline. During the 15th and 16th centuries the colonnaded prayer halls disappeared in favour of large, square, domed interiors, occasionally surrounded by lower vaulted side aisles, as in the Blue mosque at Tabriz (1437–68), famous for its faience mosaic; the imperial mosque at Isfahan (1612) retains the original court with its four impressive porches, but all the covered portions are roofed with vaults. The main prayer hall, covered by a bulbous dome, and preceded by the enormous pointed arched porch, flanked by slim minarets, is perhaps the climax of Persian mosque design.

Turkish.—It is natural that the Ottoman school should be the closest to Byzantine tradition. The Great Mosque at Konieh (1220) shows a mixture of influences—Persian, Syrian, Byzantine, Armenian. The monumental doors are Persian, but the use of carved, relief ornament borrows much from early Armenian churches. In the Yechil-Medresseh or collegiate mosque at Nycea (1420), the Byzantine influence is already dominant; dome forms, the use of alternate dark and light stones, and the entire composition are wholly Byzantine. The green mosque at Brusa (begun 1424) is noteworthy in its attempt to combine with the purely Byzantine domed scheme details such as stalactite ornament, doors in niches, surface decoration and elaborated pendentives which are distinctly Mohammedan, and developed from both Persian and Syrian sources.

The capture of Constantinople by the Turks in 1453 consolidated a tradition already strong—the attempt to build a mosque which should be structurally Byzantine, but decorated with details Mohammedan and especially Persian. The development of the mosques of Constantinople and Adrianople, from the simple dome of the Mosque of the Conqueror, at Constantinople (begun immediately after the conquest), by the Greek architect Christodoulos, and built with materials taken from the church of the Holy Apostles, to the piled masses of the Achmedieh mosque (1609), is continuous. In the piling up of dome over dome and half dome the expression of buttressing masses and the consistency of exterior effect, as well as the creation of vast, unencumbered interior spaces, the Ottoman architects went far beyond the precedent set them in S. Sophia. Although Persian tiles, and the rather garish interior painting never equalled the Byzantine marble and gold mosaic as interior decoration, the climax was reached in the mosque of Suleiman the Magnificent by Sinan (1557), whose beautiful silhouette is almost matched by the simple dignity of its interior. In the 18th century, daring lightness of construction was sought at the expense of every other quality, as in the little mosque called Nour-i-Osmanieh, "the lantern of Osman," whose dome, carried on four great arches, seems almost to float. In detail, however, European influence was making itself felt, and the building of mosques rapidly declined.

Indian.—Indian mosques usually betray the Persian origin of the Muslim conquerors. Nevertheless, as mosque building continued, more and more native influences made themselves felt. In the mosque of Ajmeer (begun 1200) the plan is of characteristic early mosque type, save that the arcades are covered by typical Jaina octagonal domes, but the front to the court, with its high, central arch, capped by twin minarets, is basically Persian. In the mosque of Kutub at Delhi, of approximately the same date, the plan is similar, but the details entirely Indian, and the great minaret (*see* illustration under Tower), with its massed alternation of vertical and horizontal shadows is characteristically Indian. In the 14th and 15th centuries, as in the mosques at Jaunpur (Redgate mosque and Jumma Musjid) the Indian delight in beam construction and the distrust of the arch give a character essentially non-Muslim. Under the Moguls there was a new influx of northern Muslim influences; the emperor Berber called to his service several pupils of Sinan from Constantinople, and the following hundred years saw the Great Mosques of Agra, Bijapur and Fathepur-Sikri, and the later work at Delhi, in which the Indian love for rich surface, the Mogul lavishness in the use of gleaming white marble, often inlaid with coloured stones, and a characteristic use of pointed, cusped arches, combined with the Persian love of great size to produce results of vivid beauty. The most important examples are the Great Mosque at Agra (middle 16th century), the mosque of Fathepur-Sikri, nearly contemporary, especially remarkable for its magnificent gateway, and the Pearl mosque at Agra, of the middle 17th century, famous for its simple plan and delicate inlays.

Chinese.—Mosques are common in China, but in almost every respect follow Chinese temple precedent slavishly. Frequently the only thing which differentiates them from ordinary Chinese temples is the existence of a Mihrab in the form of a pointed arch niche, as in the mosque at Hangchow, with decoration distantly based on Arabic sources.

Modern.—The most interesting of modern mosques is that at Paris, by Fournez, Mantout and Eustache (1922–24). This, built generally on the model of the Medresseh Bou Anania at Fez is a beautifully planned, carefully detailed and lavishly executed modern interpretation of 14th century Moorish design.

See H. Saladin, *Manuel d'Art Musulman,* v. i., 1907. *See* also MOHAMMEDAN ARCHITECTURE. (T. F. H.)

MOSQUITO, the name applied to species of blood-sucking flies belonging to the family *Culicidae,* or gnats, of the order Diptera (*q.v.*). Prior to the year 1899 mosquitoes received very little attention from entomologists and relatively few species were known. At the end of the 19th century the researches of Ross in India and Grassi in Italy proved that mosquitoes are the agents concerned with the dissemination of malaria, and the establish-

ment of this important fact has led to the collection and study of these insects in all parts of the world. About 1,500 species of mosquitoes are now recognized and it is probable that the number of kinds actually existing is nearly 2,000.

Mosquitoes bear a close general likeness to many harmless midges (*Chironomidae*) but may be distinguished by the following characters. (1) The lower lip or labium is prolonged into an elongate proboscis which forms a sheath enclosing the needle-like mouth-parts (fig. 1). (2) The presence of scales on the body, wings and other appendages. (3) The costal vein runs completely round the wing. (4) The antennae are densely plumose in the males and less hairy in the females, while the palpi project forwards and are not pendulous.

The family occurs in all parts of the world and although the tropics are much richer in genera and species than northern latitudes, mosquitoes are abundant even in arctic regions. Under the latter conditions they are found during the short summer and often occur far from the haunts of man and even in regions uninhabited by quadrupeds. In these lands they may go through a number of generations without tasting blood, nevertheless the blood-sucking instinct is so strong that they rarely fail to avail themselves of the first opportunity for responding to it that may present itself. As a rule the blood-sucking habit is confined to the female which differs from the male in possessing piercing mandibles: the males largely feed on plant juices and the females apparently subsist upon a similar diet in the absence of blood.

Breeding Habits.—The early stages of all mosquitoes are passed in water, more usually fresh and less often salt or brackish water. Some domestic mosquitoes will breed in small accumulations of water in discarded cans or other vessels: the larvae of other species occur in natural pools or ditches, while there are kinds which inhabit collections of water in hollow parts of trees or in the water-collecting receptacles of certain plants. Among other peculiar situations are pools flooded by the sea at high tides, mountain streams, wells, and the salt waters of Saharan oases. In each of these different habitats certain species of mosquitoes regularly breed and it therefore follows that knowledge of such facts is of vital importance in mosquito control. The eggs are usually deposited on the surface of the water and the number laid by a single female varies from 40–100 up to 300 or more. They may be deposited singly as in *Anopheles* or in compact masses or rafts as in the common *Culex pipiens*. The larvae are very active, with large heads and jaws and possess a pair of "brushes" which waft food-particles into the mouth. Their food chiefly consists of minute fragments of vegetable or animal matter, but some species are carnivorous, preying upon other, or even their own species. Larvae of the group *Culicinae* have a prominent breathing syphon on the 8th abdominal segment and when taking in air this organ perforates the surface film, the creature itself hanging head downwards. In the group *Anophelinae* there is no respiratory syphon and they usually lie horizontally just beneath the surface film with the plate bearing the spiracles in free communication with the outside air. The pupae of mosquitoes are active creatures, crescentic in form, and breathe by means of a pair of respiratory trumpets which break the surface film of the water when air is taken in.

FIG. 1.—RESTING POSITIONS OF (LEFT) MALARIA MOSQUITO (ANOPHELES) AND (RIGHT) CULEX

The Anopheline mosquitoes generally have spotted wings and rest with the body and proboscis in one straight line, often obliquely with the supporting surface: the *Culicinae*, on the other hand, rest with the body parallel with the supporting surface and with the proboscis inclined at an angle with the thorax (fig. 1).

Many species of *Anophelinae* act as carriers of the pathogenic organism of malaria and in Europe one of the commonest kinds thus implicated is *Anopheles maculipennis*. *Aedes aegypti* (often known as *Stegomyia fasciata*) which is concerned with the transmission of yellow fever belongs to the *Culicinae* (fig. 2). The terrible disease of elephantiasis is due to a parasitic worm being disseminated by various mosquitoes, one of the most important being the common tropical species *Culex fatigans*. Other human and animal diseases are spread by mosquitoes (*see* ENTOMOLOGY, MEDICAL).

Control Measures.—Various measures for controlling mosquitoes have been introduced. Freedom from the attacks of these insects is largely obtained by living in mosquito-proof dwellings or by utilizing mosquito curtains while sleeping. A variety of substances have been recommended for application to exposed parts of the body, essential oils of various kinds being largely advised. The destruction of mosquitoes in dwellings may be carried out by the fumigation of rooms, while traps in the form of boxes, lined with dark blue or black cloth, which can be readily closed, have been recommended. The elimination of standing water and the drainage of marshy lands afford the chief means of reducing the larval breeding-places. Areas of water which cannot be done away with are treated with oil or oil mixtures which spread to form a thin covering film, thus destroying the larvae as they come to the surface to breathe as well as acting as a deterrent to egg-laying females. Wells require screening while tanks and irrigation canals may be stored with species of fish which are known to devour mosquito larvae. Large areas of shallow swamps, rice fields and bayous in the United States have recently been dusted with Paris green discharged from aeroplanes, which has resulted in the destruction of the larvae and this method appears to promise extensive developments in the future.

FIG. 2.—AEDES ARGENTEUS (STEGOMYIA CALOPUS), A CARRIER OF YELLOW FEVER

BIBLIOGRAPHY.—The literature on mosquitoes has assumed enormous proportions; some 26 species of mosquitoes occur in the British Isles and most of them are admirably described by W. D. Lang, *A Handbook of British Mosquitoes* (London: British Museum, Nat. Hist. 1920). Much useful information relative to the British forms and control measures is also given in the pamphlet by F. W. Edwards and S. P. James, *British Mosquitoes* (British Museum: Nat. Hist. Economic series 4A, 1925). For the North American species, L. O. Howard, H. G. Dyar and F. Knab, *The Mosquitoes of North and Central America* (Washington, 1912–17, 4 vols.) is a storehouse of information: a handier and more recent treatise is H. G. Dyar, *The Mosquitoes of the United States* (Proc. U.S. National Museum, vol. lxii., 1922). For control measures *see* W. E. Hardenburg, *Mosquito Eradication* (London and New York, 1922); W. V. King and G. H. Bradley, *Airplane dusting in the Control of Malaria Mosquitoes* (U.S. Dept. of Agric., Circular 367, 1926); *see* also text-books of medical entomology. (A. D. I.)

MOSQUITO COAST or **MOSQUITO RESERVE** (Mosquitia or Reserva Mosquita), a section of the eastern coast of the Republic of Nicaragua, once held as a protectorate by the British Crown, and now comprised largely in the Province or Department of Zelaya, Nicaragua. It includes the important town of Bluefields, the town of Prinzapolca on the river of the same name, and much of the territory involved in various Nicaraguan revolutions on the Caribbean coast. The name Mosquito coast is sometimes applied erroneously to the whole eastern seaboard of Nicaragua and often to the adjoining region of Mosquitia in Honduras, *i.e.*, the coast region as far west as the Río Negro or Río Tinto. The Mosquito coast is more accurately defined, however, as a narrow strip, about 40 m. wide, skirting the Caribbean sea from 11° 45′ to 14° 10′ N., a length of about 225 miles. The northern boundary would be along the Wawa river, the western on the edge of the Nicaraguan highlands, and the southern along the river Rama. Bluefields, with a population of about 8,000, is the capital and the most important town.

The Mosquito coast is named from its ancient Indian inhabitants, the Mosquito or Misskito Indians, *see* below (the corruption of the name is attributed to the first European settlers). The Indians still have a loose tribal organization, but are completely mixed with negroes escaped from the plantations in colonial times or wrecked on the shores here. The first white settlement was made in 1630, on two small cays or islands by representatives of an English chartered company of which the earl of Warwick was chairman and John Pym treasurer. The English established a protectorate over the Mosquito Indians in 1655 and claimed this suzerainty until 1850. The United States, Spain and the Central American republics disputed this claim, and it was finally settled by the Clayton-Bulwer Treaty between the United States and Great Britain, under whose terms Great Britain withdrew her claims to the Mosquito coast in return for the mutual pledge, with the United States, that neither power would fortify, colonize or exercise dominion over any canal that should be built through Central America; this was later revised under the Hay-Pauncefote Treaty of 1900. (*See* PANAMA CANAL.) Prior to the Clayton-Bulwer Treaty, however, there had been various efforts to establish British colonies in the Mosquito Reserve, but with little success, and in 1848 the seizure of Greytown (San Juan del Norte), farther down the Nicaraguan coast, by Mosquito Indians, with British support, aroused excitement and protest in the United States, and war was talked of.

Greytown was the eastern terminus of the proposed Nicaraguan canal, and the move upon it was taken as indicative of Great Britain's determination to build a British canal through Nicaragua. The matter was closed by the Clayton-Bulwer Treaty two years later. The British Government delegated its protectorate of the Mosquito coast to Honduras, in 1859, but this was unsatisfactory both to Nicaragua and to the Mosquito Indians, and by the Treaty of Managua, in 1860, Great Britain ceded to Nicaragua all claims to the eastern coast of Nicaragua, from Cape Gracias a Dios, the present border point between Honduras and Nicaragua, to Greytown. Autonomy was granted the Mosquito Indians within the Mosquito coast deliminated above. It was also provided that the chieftain of the tribe should receive a subvention of £1,000 a year until 1870. On his death in 1864 the Nicaraguan Government declined to continue the payment to his successor, or to recognize his authority, but local Indian government continued despite this lack of Nicaraguan support. In 1880, the question, which had been referred for arbitration to the emperor of Austria, was decided in favour of the Indians, and the sovereignty of Nicaragua was limited by non-interference in local affairs. This almost complete autonomy continued for 14 years, when the Indians voluntarily surrendered it and on Nov. 20, 1894, were incorporated into the Department of Zelaya of the Republic of Nicaragua. (W. THO.)

Ethnology.—The Mosquito Indians of the Atlantic littoral of Nicaragua are a mixed race basically South American in culture. Although discovered by Columbus in 1502 they did not come into contact with Europeans until the rise of the buccaneers in the 17th century. As a result of this association they have a strong infusion of both white and negro blood. Linguistically the Mosquito are allied to their neighbours, the Sumo, and both tribes may be related to the Chibcha of Colombia. Culturally the Mosquito are canoe-using people, manufacturers of wooden bowls and spoons, bows, flutes, bark cloth, etc. They have several elaborate ceremonies marked by the excessive use of intoxicants and by conical masks suggesting those found among Amazon valley tribes. They have a tradition that long ago they lived on the Pacific coast between the Lake of Nicaragua and the ocean. Driven out by northern invaders, they moved to the present Department of Chontales. Being attacked again, they recalled an ancient prophecy that they never could be driven from the Atlantic coast and they moved there under the leadership of the national hero, Wakna. Under his son, Lakia Tara, they conquered the coast from Honduras to Costa Rica. About A.D. 1100 some strange people of higher culture settled in their territory for a time, but finally moved away again.

See E. G. Squier, *Notes on Central America* (1855); Walther Lehmann, *Zentral Amerika,* 1 teil, i. band (1920).

MOSS, a seaport and watering place of Norway, in Smaalenene *amt* (county), on the Oslo Fjord, 37 m. S. of Oslo by the Gothenburg railway. Pop. (1927) 8,453. Here was signed, on Aug. 14, 1814, the convention which united Norway to Sweden. It has sawmills, shipbuilding, and a waterproofing industry.

MOSSAMEDES: *see* ANGOLA.

MOSSLEY, market town, municipal borough, Mossley parliamentary division, Lancashire, England, 10½ m. N.E. from Manchester on the L.M.S. railway. Pop. (1931) 12,041. It lies on the river Tame, near the boundary between Lancashire, Cheshire and Yorkshire. The Huddersfield canal passes it. Ancient earthworks (Bucton castle), with a Roman road passing them, occur outside the town. Mossley has foundries, mill works, woollen factories and large cotton-spinning mills. It was incorporated in 1885.

MOST, JOHN JOSEPH (1846–1906), German anarchist, was born in Augsburg, Bavaria, on Feb. 5, 1846. He worked as a bookbinder in Germany, Austria, Italy and Switzerland (1863–1868), and then became editor of Socialist papers in Chemnitz and Vienna, both suppressed by the authorities, and of the *Freie Presse* in Berlin. For his attacks on patriotism and on conventional religion he was repeatedly arrested. From 1874–78 he sat in the German *Reichstag,* but he failed to be re-elected, was expelled by the Socialist organization, went to France, which he was forced to leave in 1879, and finally settled in London. There he founded *Die Freiheit,* and after being imprisoned for the views expressed in this journal, he went to America and resumed its publication in New York. He again suffered imprisonment in 1886, 1887 and 1902, and died at Cincinnati on March 17, 1906.

His works include: *Proletarier Liederbuch* (5th ed., 1875) and *Die Bastille am Plötzensee: Blätter aus meinem Gefängnis-Tagebuch* (1876). *See* also his *Memorien* (New York, 1903); R. Rocker, *J. Most Das Leben eines Rebellen* (1924); E. Drahn, *Johann Most* (1925).

MOST, a town in N.W. Bohemia, Czechoslovakia, on the river Bělá. Situated in the centre of a great lignite basin it is the headquarters of the State mining authority and the seat of many varied industries including sugar, chemical, porcelain and shoe factories, breweries and metallurgical undertakings. A long and stormy history is due to reasons reflected in its modern importance as a railway junction. Pop. (1920), 27,354, with a strong and growing Czech minority.

MOSTAGANEM, chief town of an arrondissement in the department of Oran, Algeria, 44 m. E.N.E. of Oran, on a plateau 278 ft. high, half a mile from the Mediterranean coast. The town is separated into European and native quarters by a deep ravine, the Ain Sefra, through which passes a considerable stream. The native quarter, called Tijit, occupies the eastern slopes of the ravine and the level ground above, and is dominated by the kubbas of two marabouts. A railway line, 122 m. long, connects Mostaganem with Tiaret, another line links it with Arzew and Oran.

Mostaganem appears to date from the time of the Almoravides. It passed into the possession of the rulers of Tlemçen and was captured by Arouj Barbarossa in 1516, and became part of his brother Khair-ed-Din's kingdom. In the 16th century the town enjoyed a period of great commercial prosperity, and its population rose to 40,000. The re-awakening of the town dates from the French occupation in 1833. Mostaganem was partly destroyed in November 1927 by a flood. Pop. 26,355, of whom 12,639 are Europeans, 10,411 being French.

MOSTAR, the capital of Hercegovina, Yugoslavia, lies on the Naretva, just south of the celebrated Naretva defile, amid gaunt and rugged mountains. It is on the road and railway from Serajevo to Ragusa, and during the Austrian occupation (1908–18) all heavy traffic between Bosnia and the Adriatic passed through Mostar. Pop. (1921) 18,176. A beautiful bridge, 61 ft. high, probably 16th or 17th century Turkish work, here crosses the river; some antiquarians, however, ascribe its foundation to the Romans, who certainly had a settlement here. Mostar is the seat of a district court and of both a Roman Catholic and an Orthodox bishop, and has a large Orthodox cathedral. It possesses a gymnasium, State schools of viticulture and horticulture, and

a State stud farm. The principal industries are wine, tobacco, fruit, vegetables and walnuts. Anthracite is found in the district.

The present name of the city is derived from the Serbo-Croatian *most*, a bridge, and *star*, old. Its earlier Slavonic name was Vitrinicha. Immediately upon their conquest of Hercegovina, the Turks chose it as their headquarters. Within a few miles are the sources of the Buna, a small affluent of the Naretva, which issues from a cavern amid scenery noted for its wild grandeur.

See Sir G. Wilkinson, *Dalmatia and Montenegro* (1848) vol. ii.; J. Asboth, *An Official Tour through Bosnia and Herzgovina* (1890); R. Munro, *Bosnia and Herzgovina* (Edinburgh, 1900), pp. 179–188.

MOST FAVOURED NATION CLAUSE, in a commercial treaty, an article which concedes to the State with which it is concluded whatever advantages in the matters comprised within its stipulations have been allowed to any foreign or third State. It does not in itself directly confer any particular rights, but sums up the whole of the rights in the matters therein mentioned which have been or may be granted to foreign countries. The value of the privileges under this article accordingly varies with the conditions as to these rights in each State which concedes this treatment.

Prior to 1778, a promise of most favoured nation treatment when granted was universally understood to mean a promise of treatment equal to the best which might be accorded to any other country, regardless of the terms under which special favours to other countries might be conferred. Owing to discriminations and exclusions by other countries, the United States found this interpretation too wide. In their first commercial treaty, that with France of April 30, 1803, Art. VIII. provided that "the ships of France shall be treated upon the footing of the most favoured nation in the ports of Louisiana." France accordingly claimed that the advantages granted to Great Britain in all ports of the United States should be secured to France in the ports of Louisiana. This claim was rejected by the United States upon the ground that the clause did not say and could not be understood to mean that France should enjoy as a free gift that which was conceded to other nations for a full equivalent. In the treaty of commerce between Great Britain and the United States of July 3, 1815, which took the place of the Jay Treaty of 1794, it was provided that "no higher or other duties shall be imposed on the importation into the territories of His Britannic Majesty in Europe of any articles, the growth, produce or manufacture of the United States, and no higher or other duties shall be imposed on the importation of any articles, the growth, produce or manufacture of His Britannic Majesty's territories in Europe, than are or shall be payable on the like articles, being the growth, produce or manufacture of any foreign country." Great Britain regarded this clause as unconditional and maintained that if one of the parties in a treaty with a third power gave a lower tariff on any such articles, the other party was entitled also to be charged at the lower rate.

The American interpretation of the most favoured nation treatment as being based on reciprocity, qualified by the power to make special arrangements with particular countries, has been upheld by the Supreme Court of the United States in *Bartram* v. *Robertson*, 122 U.S. 116, and *Whitney* v. *Robertson*, 124 U.S. 190.

The same conclusion was reached by the court of customs appeals as to concessions for reciprocal considerations made under s. 3 of the Tariff Act of 1897, in *Shaw and Co.* v. *United States*, 1 Ct. Cust. App. 426. The Court said, "S 3 of the Tariff Act 1897 was a general law: its attitude toward every nation was uniform. It offered no special favour to France or Germany or Italy or any other country. Every foreign nation was treated alike by the terms of the law. It was equally within the opportunity of England to negctiate a reciprocity treaty as it was within the opportunity of France." This American interpretation is regarded by Oppenheim as unjustifiable (*International Law*, vol. I., p. 750) and by Sir Thomas Barclay as resting on policy alone and no sound principle of law (*Problems of International Law and Practice*, p. 138). It is, however, approved by De Martens (*Traité de Droit International*, vol. II., ss. 51–55), and by Westlake (*International Law*, vol. I., p. 283). The opinions of De Martens and Westlake are to be preferred. The American interpretation rest upon a sound legal principle. The law looks to the intention of the parties to an agreement. Nations, like individuals, when they have granted mutual concessions for valuable considerations, do not usually intend to give the benefit of such concessions to third parties for nothing. If they do, they usually take care to say so in express terms, and do not as a rule leave it to be inferred from a vague general stipulation. This is not only good law, but sound common sense.

Whatever jurists may think, however, in practice the American interpretation has to be taken into account. For instance, the treaty between Great Britain and Uruguay of July 15, 1899, specifically restricts the application of the existing most favoured nation clause:—"It was also agreed that the stipulations contained in the treaty which is to be renewed do not include cases in which the Government of . . . Uruguay *may accord special favours, exemptions and privileges to the citizens or products of the United States, of Brazil, of the Argentine Republic, or of Paraguay in matters of commerce.* Such favours cannot be claimed on behalf of Great Britain on the ground of most favoured rights as long as they are not conceded to other States."

Post-War Treaties.—Since the World War the United States has made a number of commercial treaties with an unconditional most favoured nation clause. In the treaty with Germany of Dec. 8, 1923 (existing treaties between the Allied and Associated Powers and Germany having lapsed) the clause is as follows:—"with respect to the amount and collection of duties on imports and exports of every kind, each of the two High Contracting Parties binds itself to give to the nationals, vessels and goods of the other the advantage of every favour, privilege or immunity, which shall be accorded to the nationals, vessels and goods of a third State, and regardless of whether such favoured State shall have been accorded such treatment gratuitously, or in return for reciprocal compensatory treatment. Every such favour, privilege or immunity which shall hereafter be granted to the nationals, vessels or goods of a third State shall simultaneously and unconditionally, without request and without compensation, be extended to the other High Contracting Party for the benefit of itself, its nationals and vessels."

But from this all-inclusive provision the United States excepts its treatment of commerce with Cuba and its possessions. Coastwise traffic is also excepted. This measure is thus a compromise between conflicting views. "The introduction," says McClure, "of preferences in the matter of shipping would, in any but the narrowest sense, be inconsistent with, and would in all probability practically destroy the development of an unconditional most favoured nation tariff policy."

When before the Committee on Foreign Relations this treaty was declared to be a model for subsequent commercial treaties and accordingly similar agreements with similar reservations have been reached with Brazil, Czechoslovakia, Dominica, Estonia, Finland, Greece, Guatemala, Hungary, Latvia, Lithuania, Nicaragua, Rumania and Siam.

Since the Peace Treaty of 1919, Great Britain has entered into a great number of treaties of commerce and navigation in which she has taken care to make the unconditional character of the most favoured nation treatment quite clear.

The commercial treaty between France and the Seychelles islands of April 16, 1902, having been denounced, the convention between Great Britain and France of June 5, 1920, contained provisions entitling certain products of the Seychelles islands to the lowest custom duties applicable to similar products of foreign origin in France and giving a preference to French wines imported into the Seychelles islands.

In the Treaty with Latvia of June 22, 1923, the language of the most favoured nation clause becomes more precise and unconditional. The relevant provisions are as follows:—"Art. 1. There shall be between the two Contracting Parties reciprocal freedom of commerce and navigation. The subjects or citizens of each of the two Contracting Parties shall have liberty freely to come with their ships and cargoes to all places and ports in the territories of the other to which subjects or citizens of that Party are or may be permitted to come, and shall enjoy the same rights, privileges,

liberties, favours, immunities and exemptions in matters of commerce and navigation, as are or may be enjoyed by subjects or citizens of that Party. The subjects or citizens of each of the Contracting Parties shall not be subject, in respect of their persons or property or in respect of their commerce or industry, to any taxes whether general or local, or to imports or obligations of any kind whatever, other than those which are or may be imposed upon subjects or citizens of the most favoured nation."

"Art. 2. The Contracting Parties agree that in all matters relating to commerce, navigation and industry, any privilege, favour or immunity which either Contracting Party has actually granted, or may hereafter grant, to the ships and subjects or citizens of any other foreign State, shall be extended simultaneously and unconditionally, without request and without compensation, to the ships and subjects or citizens of the other, it being their intention that the commerce and industry of each Party shall be placed in all respects on the footing of the most favoured nation."

"Art. 5. Articles, the produce or manufacture of the territories of one of the Contracting Parties, imported into the territories of the other, from whatever place arriving, shall not be subject to other or higher duties or charges than those paid on like articles, the produce or manufacture of the territories of any other foreign country. Nor shall any prohibition or restriction be maintained or imposed on the importation of any article, the produce or manufacture of the territories of either of the Contracting Parties, into the territories of the other, from whatever place arriving, which shall not equally extend to the importation of the like articles being the produce or manufacture of the territories of any other foreign country."

"Art. 6. Articles, the produce or manufacture of the territories of either of the Contracting Parties, exported to the territories of the other, shall not be subjected to other or higher duties or charges than those paid on the like articles exported to any other foreign country. Nor shall any prohibition or restriction be imposed on the exportation of any article from the territories of either of the Contracting Parties to the territories of the other which shall not equally extend to the exportation of the like article to any other foreign country."

"Art. 7. As an exception from the general undertaking given by the Latvian Government to accord the most favoured nation treatment to the commerce of His Britannic Majesty's Government, it is understood that His Britannic Majesty's Government will not claim the benefit of any customs preferences or other facilities of whatever nature which are or may be granted by Latvia in favour of Russia, Finland, Esthonia or Lithuania in regard to Russian, Finnish, Esthonian or Lithuanian goods respectively, so long as such preferences or facilities are not extended by Latvia to any other foreign country."

A similar commercial convention was entered into on July 24, 1923, by the British empire, France, Italy, Japan, Greece, Rumania and the Serb-Croat-Slovene State of the one part and Turkey of the other.

In the treaty of commerce between Great Britain and Germany of Dec. 2, 1924, the most favoured nation treatment of the provisions of the treaty with Latvia is followed, subject to certain reservations as to favours granted or to be granted to third States. Similar provisions are contained in the treaties of commerce of Germany with Spain (May 7, 1926) and with Switzerland (July 14, 1927).

In the treaty of Nov. 24, 1926, between Italy and Greece the most favoured nation clause is expressly unconditional except as to favours to be accorded to adjacent States with a view to facilitating frontier traffic, such frontier zone not to extend more that 15 kilometres. The fullest most favoured nation treatment is accorded in the treaty between Switzerland and Czechoslovakia of Feb. 16, 1927, as regards importation and exportation, subject to these exceptions: "(1) In exceptional circumstances in regard to war supplies; (2) for reasons of public security; (3) to meet requirements of health and veterinary regulations with a view to the protection of animals and plants against disease, insects, parasites and other dangers of every kind; (4) in order to subject foreign goods to prohibition or restrictions which are or may in future be imposed within the country of internal legislation on the production of or traffic in and transport or consumption of native products of the same kind. This applies particularly to goods which are the subject of a State monopoly in the territory of one of the Contracting Parties."

Numerous similar treaties might be mentioned, but it must suffice to say that the most favoured nation clause which immediately after the War fell into disfavour, has again found general acceptance. In view, however, of express reservations, of attempts not infrequently made to avoid its consequences, and of the various interpretations placed upon the clause even where clearly expressed, it has been suggested that a standard form of the clause and its interpretation should be adopted by an international conference, which might be inserted in commercial treaties and which would grant the most favourable treatment, without restrictions or conditions, equal to that granted or to be granted to any third State.

See *League of Nations Treaty Series* for text of treaties; G. W. Wickersham, *Report on Most-Favoured-Nation Clause*, Publications of the League of Nations V. Legal, 1927, v. 10; *American Journal of International Law*, vol. 22, supp. no. 1, 133 (1928). (H. H. L. B.)

MOSUL, a vilayet, one of the divisions into which Mesopotamia was divided under Turkish rule, corresponds roughly to ancient Assyria. The vilayet which included the sanjaks of Mosul, Shehrizor and Sulaimaniya had an area of about 29,000 sq.m., although the actual area in dispute between Turkey and 'Iraq, and finally included in the kingdom of 'Iraq in 1926 has an area of over 35,000 sq.m. The vilayet lies mostly on the eastern bank of the Tigris: it is separated from the Bitlis vilayet and the newly constituted Hakkiari on the north by a boundary which, with slight modifications, follows the so-called Brussels or Brantling line which runs east from the Tigris through the Slopi and Lower Tiari country to the neighbourhood of the Gadir Pass. On the east the frontier line runs through the Persian mountains including the head-waters of the eastern tributaries of the Tigris. The western frontier is a purely artificial line through the Syrian desert; Baghdad vilayet forms the southern boundary. The whole vilayet belongs geologically to the Zagros mountain system and is of immense importance strategically because these mountains and their northern outliers form a very necessary and almost impregnable protective zone to Baghdad and consequently the whole kingdom of 'Iraq, which would have been seriously threatened had the vilayet remained in Turkish hands. Economically the value of Mosul is equally great. It contains vast oil resources as yet practically untapped, it forms one of the principal grain growing regions of 'Iraq, while the mountain areas produce wool, hides, gall-nuts and gum. Administratively the vilayet is now divided into the liwas of Arbil, Kirkuk, Mosul and Sulaimaniya. The population, whose exact figure is uncertain, estimates ranging from half to three-quarters of a million, is mainly Sunni Muslims. It includes Kurds, who live in valley villages for nine months in the year and migrate to the mountains of Zakho and Amadia in the summer, nomad Arabs, Christians, who constitute a very special problem (see *History* below), Turks, Yezedis and Jews.

See *Report of the Commission of the League of Nations on the Mosul Boundary* (1924–25) and "The Geography of the Mosul Boundary" (Major Lloyd, *Geographical Journal* LVIII. 1926). (L. H. D. B.)

HISTORY

By the Armistice of Mudros hostilities were suspended between Great Britain and Turkey from midday Oct. 31, 1918, at which time the British had advanced to a position north of Shergat, 60 m. south of Mosul. Nevertheless on Nov. 3 General Cassels informed the Turkish authorities that he had been ordered to advance beyond the armistice line and occupy the town of Mosul. This apparent violation of the armistice terms was subsequently declared to be justified by Article 7 of the armistice which laid down that "in the case of any situation arising which might menace the security of the Allies, the latter shall have the right to occupy all strategic points." The Turks on the other hand maintained that no such menace existed and protested strongly against this action on the part of Great Britain. Later on, further advances were made by the British forces; on Sept. 30, 1924, a pro-

visional frontier known as the Brussels Line was proposed by the League of Nations and accepted by both Great Britain and Turkey, pending a final settlement of the dispute. This Brussels line was at its nearest points no less than 150 m. north of the armistice frontier. It ran from the Hazil to the Khabur river, then across the mountains north of the valley of the Great Zab and then due east to the Persian frontier. Roughly speaking it runs on the crest of the mountains cut through by the three rivers named.

The Mandate of 'Iraq including the vilayet of Mosul was undertaken by Great Britain on behalf of the League of Nations; yet the question of the ultimate possession of the vilayet figured prominently in the discussions at the Lausanne Conference (*q.v.*). Clause 3 of the Treaty of Lausanne provided that the dispute between Britain and Turkey should be brought before the League of Nations unless settled by agreement within nine months; the Turks had agreed to this on Lord Curzon assuring them that "the decision of the council upon which the Turkish Government will be represented, will have to be unanimous, so that no decision can be reached without your consent."

In accordance with the Treaty of Lausanne, direct negotiations began in Constantinople during May–June 1924. Sir Percy Cox, the British representative with a view to securing a complete scientific frontier and a home for the Assyrian refugees demanded further the three Cazas of Julamerg, Beit-ul-Shabab (the ancient Betmanin) and Giavar lying north of the Brussels line; the Turks on the contrary refused to abate their claim to the whole of the former Mosul vilayet. The negotiations proved fruitless. In August the matter came before the League, which appointed a commission to study the question; in September the Turks crossed the provisional frontier and drove some 8,000 Assyrians to take refuge in Amadia, where they were supported by the 'Iraq Government. Thereupon at a special meeting in Brussels in October the League defined a provisional frontier, the Brussels line, which Turkey agreed to accept as a *status quo*. The Commission reached Baghdad in Jan. 1925 and suggested that Mosul should be left to Turkey if Britain intended to withdraw from 'Iraq in 1928, but assigned to 'Iraq if Britain was willing to undertake a mandate for 25 years.

Turkey contended that the League could not give a binding decision; the question was referred to the Hague Court, and was pending when further military movements by the Turks in the neighbourhood of the Brussels line in Sept. 1925 resulted in the violent deportation into the interior of Turkey of Christians living immediately to the north and in some cases even to the south of the provisional frontier; while some 3,000 Chaldeans took refuge in a destitute condition in 'Iraq. The League appointed a second commission to examine the complaints on both sides and report any violations of the frontier.

This report was presented to the League in December and left no doubt as to the harshness with which the refugees had been handled by the Turks. The ruling of the Hague Court—that an arbitral decision was binding—had already been received; but the Turkish delegate refused to accept the decision of the League and withdrew. Turkey however renewed her proposal of a plebiscite of the Mosul population, and further offered (1) a four nation Pact (Britain, Turkey, 'Iraq and Persia) which should guarantee the integrity and independence of 'Iraq; (2) the cession of the valuable Dyala basin containing some of the oil fields of the vilayet and the main sources of 'Iraq's irrigation. In the absence of the Turkish delegate, the League awarded Mosul to 'Iraq under certain conditions which were accepted by the British House of Commons five days later.

The Inclusion of Mosul in 'Iraq was finally agreed by the treaty signed on behalf of Great Britain, 'Iraq and Turkey at Angora on June 5, 1926. By this treaty Turkey accepted the Brussels line with small modifications as the frontier between Turkey and 'Iraq, the exact line to be determined by a mixed commission on the spot. A pact of security for ten years was agreed between Great Britain and Turkey and 'Iraq. Turkey enjoys a share in the royalties on Mosul oil for a period of 25 years. Subsequently an agreement was reached on the compensation to be paid for Turkish public works in the former vilayet. An exchange of notes following the treaty gave Turkey the option of capitalizing her share of the oil royalties at a present value of £500,000. This was an important event both for politics and oil.

The final Turko-'Iraq boundary line was a compromise arrangement between Great Britain and Turkey and as such it deprived the surviving Assyrian Christians of their old mountain homes in the Hakkiari and Jelu region in the north, leaving the people south of the line as refugees, and their homes north of it. It broke into two the heart of historic Kurdistan and separated from each other the two sections of the Kurdish race—the Bohtan and the Bahdinan. It interfered with the time-honoured trade route as carried on by river rafts, cutting off the regions of Jeziré-ibn-Omar and Sairt politically from their natural market at Mosul. Finally it destroyed the chances of an evolution of the Kurdish tribes as a nationality for generations to come. On the other hand it did prevent the renewal of war, at this particular time the most valuable service that could be rendered in this part of the world.

In the summer of 1927, the mixed boundary commission as provided by article 3 of the treaty completed the delimitation of the frontiers by laying down sign-posts and boundary marks. A convention was signed between the three parties concerned in November ratifying the final agreement.

MOSUL, the third most important town of modern 'Iraq, the other two large towns being Baghdad and Basra. Mosul lies on the right bank of the Tigris in 27° N. 43° E., opposite the site of ancient Nineveh, and 230 miles north-west of Baghdad. The population is estimated at between 70,000 and 90,000, mostly Muslims, although the city contains a number of people of various sects, among the most noticeable being the "Christians of St. John the Baptist" a remnant of the Gnostics. The Churches belonging to these sects are some of the most interesting features of the town. The most important Muslim building is the great Mosque, formerly a Christian Church. The streets consist of narrow undrained lanes. The houses are made either of sundried bricks or of local stone set in gypsum cement. The river is here 675 yards broad and is crossed by a bridge of boats. Mosul is the centre of an ancient agricultural district and the town is the chief market for the local products of cereals, fruit, sheep and goats. There are a large number of flour mills. Although the city no longer produces muslin, to which it originally gave the name, a good deal of weaving is still done there. As a natural corollary of the live stock production of the neighbourhood considerable leather work is done, especially shoe making and tanning. The metal workers of Mosul have also acquired a just fame, especially the sect of St. John the Baptist already referred to. In exchange for these products Mosul imports cotton goods, iron and copper, and carpets. The position of Mosul trade is however seriously hampered by geographical conditions and by a lack of modern communications. So long as trade was conducted by ancient and primitive methods the position of Mosul was very favourable. It lies on the Tigris valley road to Aleppo, the best road to the west, avoiding the danger of the Bedouins. It communicates with the Persian gulf by the Tigris river or the river road, via Baghdad; there are communications with Samsun on the Black Sea by mule or waggon to Diarbekr, and from that point on rafts down the Tigris. Mosul also lies on a caravan route to Persia via Erbid and Rowandiz. It must not be supposed that caravan methods of transport are obsolete in this region; within the last year a new route has been opened up into Persia via Rowandiz, the caravans taking up tea and returning with almonds and dried fruits, but this caravan route short circuits Mosul and goes to railhead at Kerkuk. The trade of Mosul looks mainly

southwards towards 'Iraq and the Persian gulf and in this direction it is singularly badly equipped. To the north and west Mosul is neither worse off nor better than most of the other towns and it can pick up railhead at Aleppo. South however it is in a bad position. Down the Tigris to railhead at Shergat is a desert road through an uninhabited country. The trade down the river is limited to downstream traffic, excellent for the export of Mosul's grain, but not permitting a return trade. The foothill road passes by populous centres, and has a railhead at Kerkuk. If the railway is continued through Erbil to Mosul as has been suggested, Mosul will then have an outlet for her trade in the natural direction and is likely to prove one of the most important producing centres in 'Iraq, and to revive its importance for the southern trade and also as a railhead for northern Mesopotamia and Kurdistan.

MOSZKOWSKI, MORITZ (1854–1925), Polish musical composer, was born at Breslau on Aug. 23, 1854, and studied at Dresden and Berlin. In 1897 he settled in Paris. He was a prolific composer both for pianoforte and for orchestra, but is best known by his Spanish dances, written for four hands on the piano, and his waltzes. His opera *Boabdil* was performed at Berlin in 1892. He died in Paris on March 8, 1925.

MOTACILLIDAE: *see* Wagtail; Pipit.

MOTET, a musical art-form of paramount importance in the 16th century. The word is of doubtful etymology, and probably has more than one origin. Thus *motulus* suggests *modulus* or melody, and probably connects with *motetus* or *motellus,* which designates one of the middle parts in early vocal compositions. On the other hand, the Italian word *mottetto* (diminutive of motto) suggests the French *mot* (in the sense of *bon mot*) and is associated with a profane art-form contemporary with the *conductus* and *rondel* of the 13th and 14th centuries.

The only mature art-form denoted by the word motet is that of 16th century pieces of liturgical polyphonic music in one or two (rarely more) continuous movements. The word is, however, used for any single Latin-text composition in continuous form, not set sectionally verse by verse, and not forming a permanent part of the mass. Thus Palestrina's *Stabat mater* is included among his motets; though the text is metrical and rhymed, and the style is that of the homophonic litanies. The title of motet is also loosely used for non-ecclesiastical works, such as the dedicatory motet at the beginning of Palestrina's fifth book.

The most important kind of motet is that which is written for a particular holy day. Such motets are sung between the *Credo* and the *Sanctus* of the mass. They are often founded on the Gregorian tones of their texts, and the mass is founded on the same themes, thus giving the whole service a musical unity which has never since been approached in any Church music even under Bach. When a motet was not founded on Gregorian tones it was still possible for the composer to design a mass on the same themes, and the titles of 16th century masses, when they do not indicate a secular or diplomatic origin, indicate either the motet or the Gregorian tones on which they are founded. The accompanying illustration is one of the most perfect examples existing, and the illustration in the article Mass shows how Victoria uses the themes of this motet in his mass with the same title. In the present illustration, the bar-strokes (unknown in 16th century part-books) are drawn irregularly so as to show the free rhythms. Typical points are the runs and slow triple rhythm at "gaudent"; the note-against-note swinging rhythm at "amicti stolis albis" and the naïve illustration of "sequuntur Agnum." When such a motet is associated with a mass it is a crime to perform the mass without it. Sometimes one composer founded a mass on another composer's motet; thus Soriano's fine *Missa Nos autem gloriari,* is based upon a motet by Palestrina, and Palestrina's Missa *Quem dicunt homines* is on a motet by Willaert. When a motet was in

Original notation a 3rd lower, but this is about the pitch intended. The note is Hypomixolydian (VIII). The first note in the treble is a Long, = 2 breves = 4 semibreves.

T. L. da Victoria. 1st book of Motets.

two movements the second movement always ended with the last clauses of the first, both in text and in music, thereby producing a distinct impression of *da capo* form.

In later times the term motet indicates any piece of Church music of clearly single design, regardless of language or of place in a liturgy. Bach's motets are great German choral works in several movements, with no written accompaniment, though there is internal and external evidence that they were accompanied from score by the organ. The Motet Choir of the Thomas-schule at Leipzig was Bach's second choir, junior to his Cantata Choir. Handel's motets belong to his Italian period and are Latin cantatas with instrumental accompaniment. (D. F. T.)

MOTH, in entomology, any lepidopterous insect in which the antennae or feelers taper to a point or, if clubbed, as in butterflies, the two wings of a side are held together by a bristle or frenulum; the latter device is never found in butterflies. (*See* LEPIDOPTERA.)

MOTHER, the female parent of a child. The word, like father, is common to Indo-Eur. languages (*cf.* Ger. *Mutter,* Lat. *mater,* Fr. *mère*). The Skt. *mata* points to an original derivation from a stem *ma,* to measure, or make. As a title "mother" is applied to the head of a religious community of women. (For "mother-of-pearl" *see* PEARL.) There is a particular application of "mother" to the scum which rises to the surface of a liquor during the process of fermentation, and also to a mass of gummy, stringy consistency formed in vinegar in the process of acetous fermentation, hence known as "mother-of-vinegar" (*see* VINEGAR). This is probably derived from Du. *modder,* mud, mire.

MOTHER-OF-PEARL, a substance which lines the interior of many species of molluscs; it is similar in nature to the pearl itself. Its beautiful iridescence and lustre are due to that well-known optical phenomenon, the interference of light. It is extensively used in decoration for inlays, for the handles of knives and for cheap jewellery. (*See* PEARL; LIGHT.)

MOTHER RIGHT: *see* MATRIARCHY.

MOTHERS' PENSIONS: *see* PENSIONS IN THE UNITED STATES; NATIONAL INSURANCE; WIDOWS' AND ORPHANS' PENSIONS.

MOTHERWELL, WILLIAM (1797–1835), Scottish poet, antiquary and journalist, born at Glasgow on Oct. 13, 1797, was sheriff-clerk depute at Paisley in 1819. He collected materials for a volume of local ballads, *The Harp of Renfrewshire* (1819). In 1827 he published *Minstrelsy Ancient and Modern,* with an excellent historical introduction. He contributed verses to newspapers and magazines, *Jeanie Morrison, My Heid is like to rend, Willie* and *Wearie's Cauld Well* being his best-known poems. He became editor of the *Paisley Advertiser* in 1828, and of the *Glasgow Courier* in 1830.

A small volume of his poems was published in 1832, and a larger volume with a memoir in 1846, reissued, with additions in 1848.

MOTHERWELL AND WISHAW, a police burgh of Lanarkshire, Scotland. Pop. (1931), 64,708. It is situated near the right bank of the Clyde, 13 m. S.E. of Glasgow by the L.M.S. railway. Motherwell takes its name from an old well dedicated to the Virgin, and the burgh owes its rapid increase to the coal and iron mines in the neighbourhood. It has large iron and steel works, and bridges, steam-cranes, iron roofs, etc., are made Motherwell and Wishaw were united into one burgh in 1920.

MOTION: *see* PRACTICE AND PROCEDURE.

MOTION, LAWS OF. Before the time of Galileo (1564–1642) very little attention had been paid to scientific study of the motion of terrestrial bodies. With regard to celestial bodies the case was somewhat different. The regularity of their diurnal revolutions could not escape notice; and before the end of the 2nd century A.D. the Greek astronomers had observed and recorded a great deal about the more complicated motions of the sun and moon and planets. They adopted uniform motion in a circle as a fundamental type of motion, and expressed the motion of each body by a combination of motions of this type. This scheme did not suggest any relation between celestial and terrestrial motions. Copernicus (1473–1543) simplified it by taking the sun as the centre of the solar system. The first astronomical discovery which was a direct contribution to a general theory of motion was made by Kepler (1571–1630) a contemporary of Galileo. A time had come, at the end of the 16th century, when the theory of planetary orbits, from which tables were calculated, had been shown to be seriously faulty. So it was necessary to correct it, either by a rearrangement of the old scheme, or in some other way. Kepler undertook the difficult work of reconstruction, stimulated by a conviction that there was something of an orderly kind to be discovered; and in 1609 and 1619 he published his new laws of planetary motion. (*See* ASTRONOMY.) The establishment of the approximate agreement of these laws with a theory of motion founded on terrestrial experiments was one of the first steps in Newton's subsequent work on the subject.

Galileo.—About 1590 Galileo made his famous experiments on the motion of falling bodies. Taking account of the resistance of the air, he arrived at the conclusion that, in a vacuum, all bodies would fall in exactly the same way, namely, with a certain constant acceleration. This may be called Galileo's acceleration. He also found that bodies allowed to slide down a smooth fixed inclined plane moved with constant acceleration, which diminished as the angle of inclination was reduced; and he inferred that an unimpeded body, moving on a smooth horizontal plane, would move with uniform velocity in a straight line. Dealing then with projectiles, he treated their motion as the result of compounding horizontal motion with constant velocity and vertical motion with his constant acceleration, so that the path of a projectile, in a vacuum, would be a parabola. This composition of motions is illustrated by the path of a stone dropped from the mast of a ship, sailing at uniform speed, so that it alights at the foot of the mast. These results, and Galileo's careful teaching, some of which is recorded in his dialogues, effectively introduced a new view of the whole subject, namely, the idea that the acceleration of a moving body is the feature of its motion which the surrounding conditions determine, and that, if it were freed from all influence due to other matter, it would move with uniform velocity in a straight line. This doctrine, and Galileo's composition of motions, are directly applicable only to a body whose motion can be treated geometrically as that of a point. But any material system can be regarded as built up of particles of this character, conceived to be as small as may be necessary for the purpose of calculations.

The most important contributor to the subject, in the period between Galileo and Newton, was Huygens (1629–95). He investigated the acceleration of a point moving in any curve, and understood the nature of centrifugal force; and when it was discovered, by means of clocks, that the acceleration of falling bodies varies with the latitude, he suggested the earth's rotation as a cause of this. He also took the considerable step of comparing the motions of pendulums consisting of rigid bodies of various shapes, finding their centres of oscillation. He based this calculation on an assumption which amounted to a denial of what is popularly called perpetual motion. It would be classed now as an application of the theory of energy. At the same time various experiments were made on the collision of hard bodies, establishing a comparison of their masses by inertia, which agreed with the comparison by weighing. Inertia is the general term applied to the resistance of bodies to a change of motion.

Galileo-Newton Theory.—We owe to Newton (1642–1727), the consolidation of the views that were current in his time into a general theory of motion, the application of which, throughout the solar system, satisfied the requirements of astronomy, and at the same time placed terrestrial dynamics on a sound footing. This may be called the Galileo-Newton theory. It has been adopted ever since as the foundation of dynamics, except so far as its scope has been restricted by the theory of relativity (*q.v.*). It was expounded by Newton in the *Principia* (1687), the link connecting the acceleration of falling bodies with celestial motions being supplied by the law of gravitation. The Galileo-Newton theory, in combination with the law of gravitation, has been verified within the solar system to a high degree of accuracy, though not flawlessly; and it is inferred to be more generally valid. It assumes a space with Euclidean geometrical properties. This is a proper and useful assumption, so far as it will carry us.

For the purpose of the Galileo-Newton theory of motion, mass is the property of a body which is exhibited by inertia. It is shown, for example, by the difficulty of stopping a rapidly rotating grindstone, compared with a similar body made of wood. Presumably this would be the same on the moon as on the earth. Newton conceived mass to be an inalienable property of every portion of matter, such that the mass of any body is equal to the sum of the masses of its parts, and is expressible arithmetically by its ratio to the mass of a standard body. He regarded this property of terrestrial bodies as having been established consistently. The ratios to one another of the masses of celestial bodies were to be chosen to fit the theory of their motions. Newton called his measure of time an absolute measure, and it may be defined as the measure of time which all practical clocks aim at recording. A clock is an instrument which counts the repetitions of some operation, such as the swing of a pendulum, which is repeated under conditions as nearly as possible identical; and it is assumed that all operations give the same measure of time. (*See* TIME, MEASUREMENT OF.) The rotation of the earth is found to be more accurate than any clock, and is therefore referred to as a standard.

Newton required, for the measurement of motion, the specification of a base relative to which it is to be reckoned. Such a base might be the walls and floor of a room, or of a cabin of a ship, or any other rigid frame with regard to which all points have distinct measurable positions. A bead moving uniformly on a cord, stretched between two legs of a table, has uniform velocity in a straight line relative to the table. But if the table is being moved about a room, the bead has a quite different motion relative to the walls and floor of the room. Newton's procedure practically amounted to choosing a base such that the motions of bodies, relative to it, would conform to his laws. Their observed motions were to be reduced to order in this way. He called motion relative to this base absolute motion. The base is sometimes called a Galilean base. The laws of motion deal only with changes of velocities; therefore if a Galilean base has been found, any other base which moves relative to this with uniform velocity, without rotation, is also a Galilean base. The key to the discovery of such a base is that the mutual forces, which are now to be defined, between any two particles, are to be equal and in opposite directions. The base adopted is a base attached to the centre of mass of the solar system, and without rotation relative to the directions of the fixed stars.

The laws governing motion relative to a Galilean base may be stated as follows: A material system is conceived to consist of particles, represented geometrically by points, to each of which

a mass is assigned. Any given particle, A, of mass m, has a certain acceleration, f, in a certain direction. To account for this acceleration, it must be the resultant of a number of accelerations, α, β, . . . , each along the line from A to some other particle. Multiply each of these accelerations by m, so that we have quantities mf, $m\alpha$, $m\beta$, . . . each of them associated with the direction of the corresponding acceleration, and such that the first of them is the resultant of all the others, according to the law of composition followed by accelerations, that is to say the parallelogram law. The first is called the *resultant* force acting on A, and the others are called *component* forces in the lines joining A to other particles. All other particles, B, C, . . . are to be treated in the same way. And the theory is that this can be done so that the component force applied to A, in the line AB, is equal and opposite to the component force applied to B in this line, and the same for other pairs of particles. Masses being suitably assigned to the bodies in question, all accelerations relative to a Galilean base are to be attributable, in this way, to equal and opposite forces between pairs of particles. This implies that the centre of mass is a point whose acceleration is zero. In general, any actual calculation deals only with a portion of the whole system; so that the forces to be taken into account are the mutual forces between the bodies in question, and so called external forces representing the influence of external bodies.

The Law of Gravitation.—The application of this theory of motion depends on the discovery of a classification of forces, or laws of force. We have experience of mutual actions between terrestrial bodies, such as pressure between bodies in contact, and magnetic attractions and repulsions. To this experience Newton added the law of gravitation, namely that between any two particles there is a force of attraction, proportional to the product of their masses, and inversely proportional to the square of the distance between them. It might be supposed that this law could be tested at once by laboratory experiments, but the force between bodies that can be handled is so small that it is difficult even to detect it; thus Newton depended mainly on astronomical verification. Laboratory measurements have been made since, from 1798 onwards, in particular cases; the principal result being that the mass of the earth in pounds is known. Newton made an estimate of this which proved to be nearly correct, but it was not essential for his work.

In the *Principia* we have Galileo's acceleration attributed to gravitation, and shown to be consistent with the moon's orbit about the earth; there are also calculations, according to the law of gravitation, extending to the whole solar system, treated as isolated, including the theory of precession of the equinoxes due to motion of the earth's axis. The orbits of comets, and the theory of tides, and a variety of other problems, are also considered. The verifications of the Newtonian theory, thus obtained, were overwhelming. Kepler's laws, with a slight modification introduced by Newton in the third law, were shown to agree with the orbit each planet would perform if it and the sun alone existed; and the perturbations of these orbits, so far as they had been detected, to be such as might be attributed to the coexistence of all the planets. With regard to the perturbations of an orbit of one body about another, due to a third body, the best data at Newton's disposal were the irregularities of the orbit of the moon about the earth. Attributing these to the disturbing influence of the sun, Newton showed how they could be accounted for—a remarkable mathematical feat for a first attempt at a thing of this kind.

Relativity.—Further verifications of the Newtonian scheme for the solar system were carried on during the next two centuries. They were not absolutely perfect; but no definite establishment of a flaw in the theory occurred till 1915, when a small error in the motion of the planet Mercury, as calculated from known data by Newton's methods, was shown by Einstein to be accounted for by his theory of relativity. Seventy years earlier, when Uranus seemed to go astray, the errors were accounted for by perturbations due to the planet Neptune, previously unknown. For Mercury a similar explanation had been diligently sought, but had not been found. The theory of relativity is held to have established that, for a planet so near the sun, and possessing, as Mercury does, an orbit whose eccentricity is not very small, Kepler's elliptic orbit is at fault to a perceptible extent, and will be replaced by a slightly different fundamental orbit. The solar eclipses of 1917 and 1922 confirmed this by showing apparent displacements of stars seen near the sun which were predicted by the theory of relativity; a new property of bodies, associated with mass, being thus verified. The result is that the Newtonian theories have become an approximately correct fragment of a wider and more fundamental theory, and their scope and degree of accuracy have been to some extent ascertained.

Every scientific theory is provisional, and is subject to corrections and limitations; and the discovery of these is an important step in the direction of progress. E. Mach's *Science of Mechanics* may be consulted with reference to difficulties that have been felt in the past with regard to a presumed universal validity of the Newtonian apparatus. Such difficulties are now happily at an end, and the measures of mass by inertia and by gravitation are rationally harmonized. (*See* RELATIVITY.)

Terrestrial Dynamics.—Let us return now to terrestrial dynamics, dealing with the motion of material bodies relative to the earth. Here the Newtonian theories are found to be sound; but all exact calculations are rather complicated, chiefly on account of the earth not being a Galilean base. Practically it is necessary to discover, for each class of problem, what sort of approximation gives a sufficiently correct result. The simplest approximate device, in many cases sufficient, though no feature of it is accurate, is the obvious one of treating the earth as if it were a Galilean base, and applying to each particle its weight by way of external force, treated as constant. Here weight is not technically a force, but is employed to represent the joint effect of gravitation and the earth's motion. It is Galileo's acceleration multiplied by the mass of the particle. A closer approximation to exact conditions gives a falling body a divergence from the plumb-line vertical, which would amount to about half an inch in a fall of 230ft. at the equator. This sort of effect is shown clearly by the trade winds. The theory of such an apparatus as Foucault's pendulum, or the gyro-compass (*see* GYROSCOPE), requires more exact account to be taken of the earth's motion. And in the theory of ocean tides, the main factor is the diurnal variation of gravitational force, due to changes in the positions of the sun and moon relative to the earth as it rotates. Here we have a thing which should affect the regularity of a pendulum clock; but, when the magnitude of the effect on a clock is calculated, it is found to be too small to be observed. (*See* MECHANICS and TIDES.)

The 19th century saw the important development of the theory of energy, which linked the dynamics of material bodies with other branches of physics and with chemistry, and thus stimulated wider applications of dynamical theory. But the quantum theory (*q.v.*) has now demonstrated limitations of this procedure in the case of atomic systems. Thus we see that, during the first quarter of the 20th century, a definite thing has been accomplished with regard to the Newtonian theories, in that the range over which they are practically valid, which had remained uncertain for more than two centuries, has been to a considerable extent marked out.

MOTION PICTURES. The motion picture is the latest machine tool in the service of expression. The endeavours to transmit emotional stimuli and experience by re-creating events have resulted in language, oral and written, the plastic and graphic arts, the stage, music and lastly the screen. Hitherto, motion had been consciously contrived for and successfully *suggested* in the fine arts, *e.g.*, in the cavalcade in the frieze of the Parthenon. The

THREE IMPORTANT EARLY FILMS

1 and 2. Scenes from D. W. Griffith's production of the Civil War film, "The Birth of a Nation" (1914). In this historically important classic of American motion pictures, the technique of the drama was blended with the capacities of the camera, thus laying the foundation of modern screen technique

3. Sarah Bernhardt in "Queen Elizabeth," the first feature-length production, released by Adolph Zukor (1912). This four-reel drama, Europe's most pretentious effort at the time, instituted the "feature-picture" era

4. A scene from Mary Pickford's production of "Little Lord Fauntleroy," an early example of double exposure. Miss Pickford played both the part of the boy Cedric, on the right, and that of "Dearest," his mother, the younger woman in the group on the left

WORKROOMS AND SETS IN A MOTION PICTURE STUDIO

1. Aerial view of a motion picture studio lot
2. Shoe racks in a woman's wardrobe department
3. Wild animal photography in the studio. A fight between a mongoose and a snake, which when filmed will appear to have taken place in a natural desert setting
4. The workroom in the women's wardrobe department
5. Studio setting for "The Trial of Donald Westhof," showing a busy street scene. The upper parts of the buildings are not built into the set but are photographed from models constructed in miniature
6. Studio setting for a Siberian salt mine

motion picture camera brings action into graphic art.

The motion picture first emerged from the laboratories of abstract science in 1894 as the Edison peep-show device known as the kinetoscope. By 1925 the motion picture seemed ready to begin clarification and refinements of its technique. Hardly had this apparent position been reached when the electrical and radio laboratories brought forth an array of improved photo-electric cells and methods of electrical amplifications which by 1928 resulted in the spectacular and revolutionary intrusion of the sound or "talking" picture.

Contrary to popular belief, this development of the talking picture in 1927–28 was the first true junction of the motion picture with electrical science. The silent motion picture, being mechanical, optical and chemical, was in no way an electrical invention, nor, in any strict sense, dependent upon the service of electricity. The talking or sound picture is, however, electrical in that it is a device for the conversion of sound vibrations into electrical light variations photographically recorded, to be in turn electrically reconverted into sound.

History.—For the development of photography see that article. The scientific study of the optical appearances of objects in motion had begun with the investigations of Peter Mark Roget in England, resulting in a paper presented by him, under the title of "The Persistence of Vision with Regard to Moving Objects," before the Royal Society in 1824. Roget's paper inspired several scientists to engage in various experimental investigations, among them Sir John Herschel, and Michael Faraday. In Europe, Dr. Joseph Antoine Plateau of the University of Ghent and Dr. Simon Ritter von Stampfer, in Vienna, simultaneously discovered a method for viewing a series of pictures, representing phases of motion. The pictures were mounted in chronological sequence on the rim of a disc and were observed through slots in a similar disc mounted on the same rotating shaft. The pictures, antedating photography, were necessarily drawings of assumed phases of motion. Baron Franz von Uchatius, an Austrian artillery officer, in 1853 combined the disc device with the magic lantern and projected the pictures upon the screen. The capacity of the machine was obviously limited to a short cycle of movement. The Plateau-Stampfer labours gave rise subsequently to the invention of the zoetrope, or "wheel of life," which continues to be a familiar toy.

Photography.—As early as Leonardo da Vinci's experiments, photography (*q.v.*) had been in slow evolution. In 1860, Coleman Sellers, a mechanical engineer, in Philadelphia, made the first known endeavour to relate photography to the principle of the zoetrope. He posed his sons in a series of photographs showing them, in successive phases of a cycle of action, driving a nail into a box. The photographs were mounted on the blades of a paddle wheel, which when revolved from a given point of view produced a zoetropic effect. This machine was patented as the kinematoscope in the United States (Feb. 5, 1861). Photography then required exposures so long that a true record of motion was not possible.

A complete anticipation of the motion picture was embodied in a patent application by Louis Arthur Ducos du Hauron, in France, filed April 25, 1864. The Sellers method of photographing posed phases of motion was applied to a projecting zoetropic device by Henry Renno Heyl, an engineer and inventor, in Philadelphia, exhibited on Feb. 5, 1870. This was in effect the application of photography to the invention of Baron Uchatius. The Heyl device was christened the phasmatrope. It carried photographs of six poses of a waltzing couple, repeated three times, giving a capacity of 18 pictures. It is of interest to note that the wheel on which the pictures, glass plate transparencies, were mounted was actuated by a ratchet and pawl mechanism giving each image a period of rest on the screen, a method and principle which had to be rediscovered a quarter of a century later.

Two years later, in 1872, and without any intended relation to motion picture development, Leland Stanford, a California railway magnate and sportsman, wished to investigate the gaits of the horse. Stanford assigned the photographic problem to John D. Isaacs, an engineer on the staff of the Central Pacific railway. Isaacs contrived a battery of cameras with electrical shutter controls. The shutter mechanisms were improved and the speed of photographic materials was increased, permitting at last the first real photographic records of objects in rapid motion. Exposures as brief as $\frac{1}{2,000}$ of a second were made. Eadweard Muybridge operated the Isaacs apparatus installed at Palo Alto on Stanford's stock farm. The pictures made were records in analysis of motion. Synthesis was still to come. (A description of these experiments was published in Dr. Wellman's *The Horse in Motion as shown by Instantaneous Photography*, London, 1882.)

While visiting in Paris, Stanford displayed some of these pictures and word of them reached Jean Louis Meissonier, the painter, who was then in a heated controversy with French academicians over the postures of horses in his pictures. Meissonier sought Stanford and found vindication in the photographs from California. The artist prevailed on Stanford to send Muybridge to France. The differing academicians were confronted with the photographs, and as a final proof Meissonier synthesized the photographic analysis into motion pictures by projecting transparencies on a machine similar to the Heyl phasmatrope.

The method evolved by Isaacs and operated by Muybridge resulted in a changing point of view for the pictures as the action swept past the battery of cameras. The pictures obtained, synthesized on the screen gave the illusion of the moving object in a single spot while the scenery ran past. Wallace Goold Levison of Brooklyn, N.Y., devised a camera which exposed successive plates in a single camera, obviating this difficulty. It was utilized only for scientific demonstration.

Edison's Inventions.—In 1887, Thomas A. Edison of New Jersey, attacked the problem. He was aware of Muybridge's product. But Edison's efforts were dominated entirely by the phonograph idea. His first motion picture machine recorded spirals of tiny pictures on a cylinder, in the pattern of a phonograph groove. The pictures were given an intermittent motion and viewed under a microscope. The results were inadequate and Edison determined upon larger images to be handled on a tape or belt. He built a device for this purpose and experimented with various materials, including films made of collodion varnish coated with photographic emulsion. The material was unsatisfactory. In Aug. 1889, George Eastman of Rochester, N.Y., began the manufacture of photographic film on a nitro-cellulose base, a material evolved to meet the mechanical problems of "roller photography" for the Eastman Kodak. Edison heard of this material and purchased a sample strip 50 ft. in length for $2.50 and tried it with success in his picture machine. The demonstration of the Edison kinetoscope at West Orange, N.J., on Oct. 6, 1889, with a strip of Eastman film made the motion picture an accomplished fact.

The Kinetoscope.—The kinetoscope was a peep-show device in which the film ran with a continuous movement between a magnifying lens and a light source. The capacity of the machine was limited to 50 ft., the length of the tables on which the film was manufactured, which gave a motion record of 48 exposures a second, and lasted about 13 seconds. The size of the film, the image and the arrangement of the sprocket holes by which the film was driven in that first machine, continue as the standard of the motion picture of to-day. The machine was patented by Edison in 1891 in the United States only. It stood idle in his laboratory until it came to the attention of Thomas R. Lombard, of Cornelia, Ga., a promoter of the phonograph, who sought it as a novelty for display at the Columbian Exhibition in Chicago. The machines, despite statements to the contrary, were not ready in time and made their first public appearance at a kinetoscope parlour at 1155 Broadway in New York city, April 14, 1894. Thus began the commercial history of the motion picture.

That autumn several machines were exported. From these machines the English and European development of the motion picture sprang. Edison's invention was not protected by patents abroad. The pictures for the kinetoscope were produced at West Orange in a tiny studio costing $637.67. The invention of the motion picture had now cost Edison $24,118.04. The tar paper studio, dubbed "The Black Maria," revolved to keep the stage in sunlight. The kinetograph, or camera, was almost a ton in weight

and all events had to be brought to it. The subjects were necessarily those restricted in range of action: bits of vaudeville acts, snatches of prize fights and dances.

By the winter of 1894 a demand arose for a machine which should combine the kinetoscope's film record with the magic lantern so that the picture might be liberated from the peep-show and shown to a large audience for greater revenue. Edison had experimented in projection but discouraged the idea, expressing the belief that exhibitions to large audiences would too rapidly exhaust the novelty of the pictures. Several other experimenters attacked the problem of projection. On Feb. 22, 1895, Maj. Woodville Latham, of Virginia, a Confederate ordnance officer in the American Civil War (father of Otway and Grey Latham, kinetoscope exhibitors), gave a New York press exhibition of his pantoptikon, projecting a kinetoscopic film. On May 20 this machine was placed on public exhibition. It was highly imperfect. A second version of this device had a brief international career under the name of the eidoloscope. A more satisfactory machine known as the cinematographe was produced by Louis and Auguste Lumière, photographic manufacturers at Lyons, France. They took out a French patent on Feb. 13, 1895, and demonstrated their machine March 22, 1895, in Lyons.

The Vitascope.—In June 1895 Thomas Armat of Washington discovered the principle of the modern projector, a film movement which gave each successive image a period of rest and illumination in excess of the period of movement from image to image. This machine was first shown publicly at the Cotton States exhibition at Atlanta, Ga., in Sept. 1895. It displayed Edison kinetoscope pictures. It was subsequently known as the vitascope. In Feb. 1896 Robert W. Paul of London, manufacturer of scientific instruments, gave a demonstration of a projection machine called the theatrograph. He had meanwhile manufactured duplicates of the kinetoscope, and had produced films for these machines with a camera of his own devising.

The commercial career of the motion picture on the screen began with the presentation of the Armat machine as the vitascope at Koster and Bial's music hall at Herald square in New York on the night of April 23, 1896. A vaudeville career opened before the motion picture and the capacity of the machine was quickly increased to 1,000 ft. of film (sufficient to occupy the typical time of a stage turn), thus establishing the existing standard film unit of one reel.

The Lumière influence on the art soon became important. The cinematographe was adjustable, making it a camera, a film-printing machine and a projector. It was mobile and could record the outdoor world. The Lumières also reduced the rate of exposure from Edison's 48 images a second to 16 a second, the theoretical standard of the silent pictures of to-day. The Lumière photographer-exhibitors were sent touring around the world carrying the films to far places and recording remote peoples for the screens of Europe and America.

The development of the art was, however, for some time under two important early handicaps. In Europe the screen suffered from the Charity Bazaar fire in Paris, May 4, 1897, in which 180 people perished. The fire was traced to the motion picture machine. That autumn Edison launched a legal campaign for the protection of his invention from infringers and competitive machines and a violent and involved patent war hampered the industry for more than a decade. In that same year, 1897, R. G. Hollaman of the Eden Musée on the roof of a New York office building, produced the Passion Play in three reels, with a cast and dramatically arranged settings, thus instituting production for the camera. Meanwhile in March of that year, Enoch J. Rector, earlier associated with the Lathams, had pictured the Corbett-Fitzsimmons fight at Carson City, Nev., in some 11,000 ft. of film.

The motion picture still continued as an incident of vaudeville. About 1909 George Melies of the Théâtre Robert Houdin in Paris, a magician, applied the camera to feats of magic and gave the motion picture new life, incidentally adding fade-outs, dissolves and double exposures, now commonplaces of the technology. In 1903, Edwin S. Porter, an Edison cameraman, alarmed at the decline of the industry, sought to give it new impetus by novelty. He compressed all the known thrills of the screen into a single picture, *The Life of an American Fireman.* This succeeded so well that he tried again with a cheap novel story entitled *The Great Train Robbery.* This picture, occupying a whole reel in length, established the "story picture" and founded the art of narration for the motion pictures, and placed them on an independent basis. With this production for its programme the first motion picture theatre, a "nickelodeon," was opened in Pittsburgh, Pa., in Nov. 1905, and started the screen on a new career.

(T. RA.)

MOTION PICTURE PRODUCTION

Early Pictures.—The first story pictures were simple. Like the earlier topical novelties, they were merely records of events. In 1907 David Wark Griffith, a young American director, evolved a screen technique of far-reaching significance. He brought into first practical use certain methods of pictorial emphasis, such as the "close-up," "cut-back," "fade-out" and "dissolve." The story pictures of this period were in one reel. *Ben Hur* was made in 1907 in 16 scenes. Multireel pictures began to appear in 1909 but the sentiment of exhibitors was strongly against them and they were released one reel at a time. A year later screen history was made by releasing multireel pictures in their full length.

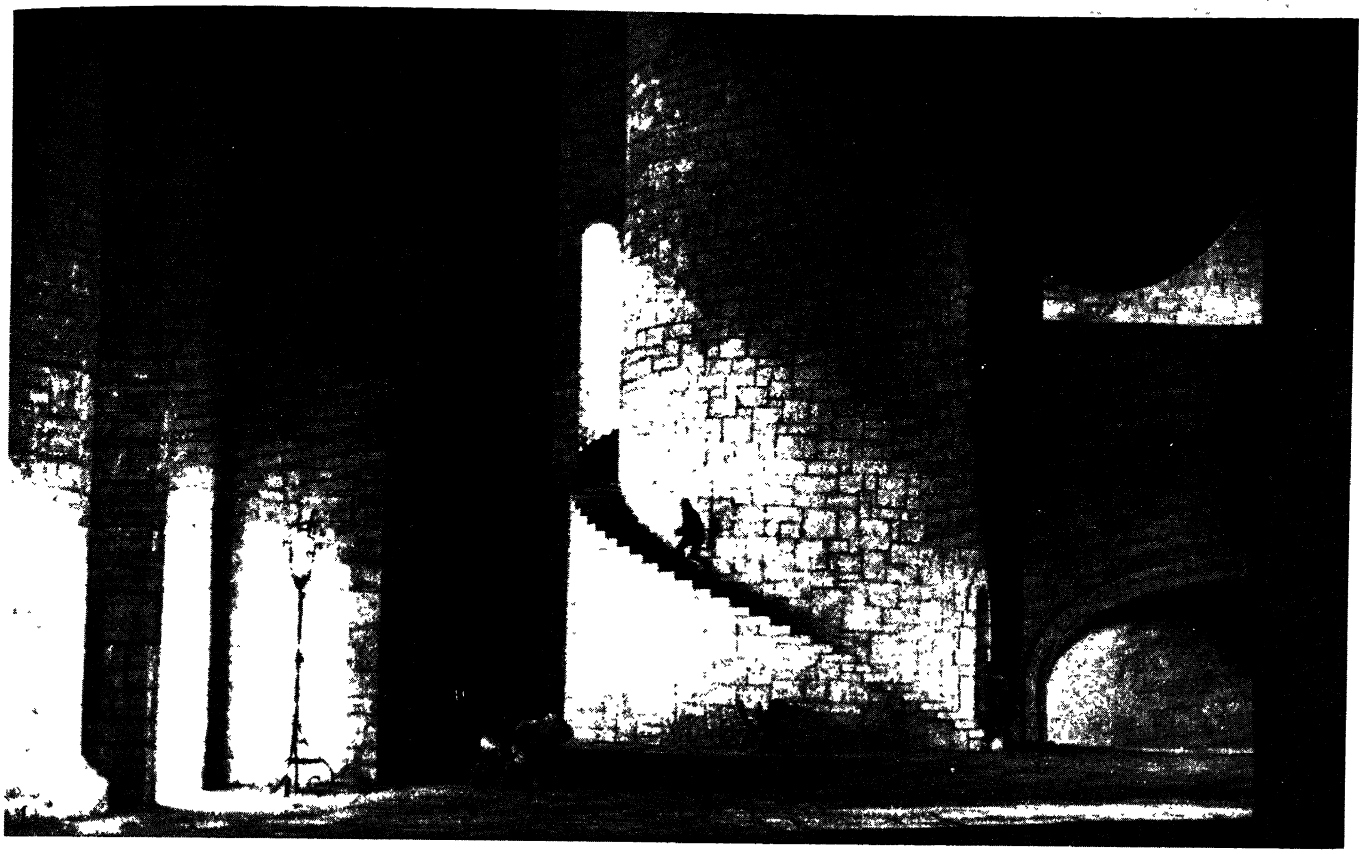
Progress.—Many of these early productions, aiming at sensational entertainment, overstepped the bounds of good taste. The advent of Griffith and a few others had a refining influence; the themes and characters were humanized and a technique was evolved which disclosed the dramatic possibilities of the screen to an extent hitherto undreamed. The one-reel pictures passed into virtual obscurity as pretentious productions using three, four, five and six thousand feet of film were made.

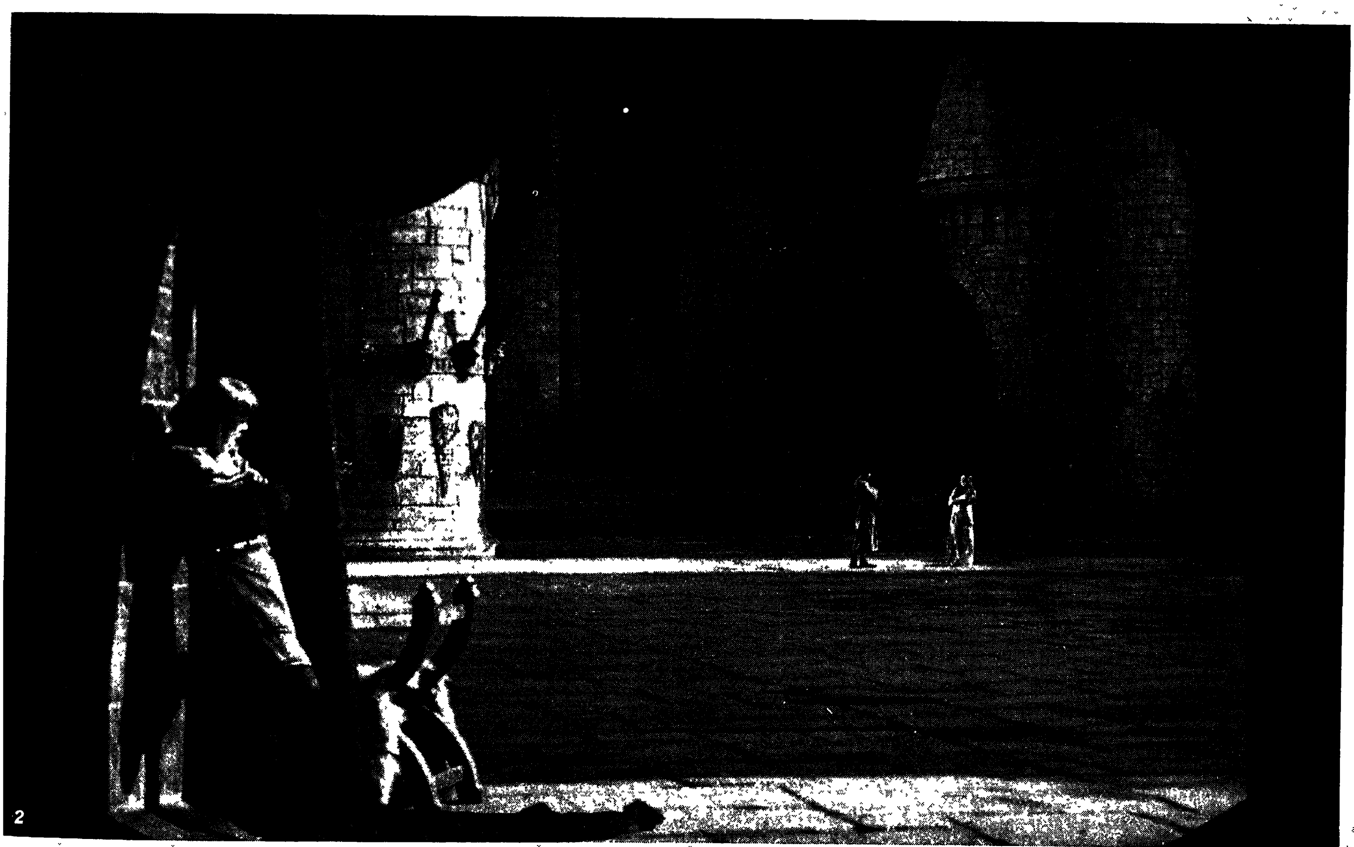
For many years the players appeared under a mask of anonymity, but as certain of them were seen with recurring frequency, the public began to anticipate them in future pictures. Favourites were created which resulted in "stars." While the majority of the stage artists regarded pictures disdainfully, a few were prevailed upon to pose before the camera. It was the idea of Adolph Zukor, a pioneer producer, to bring famous names to the screen in famous plays. The success attendant upon his exhibition of Sarah Bernhardt in *Queen Elizabeth* in 1912 indicated the merit of his idea. Zukor's influence was felt throughout the entire industry. Producers who had heretofore concentrated on one-reel pictures now engaged in multireel enterprises. From 1912 to 1915 was a period of transition in which Zukor led the way to what is now known as feature pictures. *Quo Vadis* in 8 reels in 1913 met with unusual success and gave greater impetus to the Zukor idea. This picture also brought into being the road-show style of presentation whereby a legitimate theatre was leased for the exhibition of pictures, instead of the "nickelodeons" which then prevailed.

Griffith brought to the screen in 1913 a new conception of screen entertainment with *Judith of Bethulia.* The same year Jesse L. Lasky, in conjunction with Cecil B. DeMille, established a studio in California and produced *The Squaw Man.* The most stupendous undertaking in the films during this period occurred the following year when Griffith produced *The Birth of a Nation,* in 12 reels. The wave of public excitement which followed in the United States showed in a greater measure than ever before the far-reaching influence of motion pictures. It was at this stage of cinema history that Mack Sennett, who made comedies in California, upset screen traditions by producing a multireel comedy, *Tillie's Punctured Romance.* The serial idea had its inception at this time and met with great success in addition to creating several new "stars." *Intolerance,* produced by Griffith in 1916, was yet another milestone in the early history of the films, although it did not achieve the signal success of *The Birth of a Nation.*

MODERN TENDENCIES

Internationalization of Cinema.—The ability of pictorial art to cast aside the barriers imposed by languages made it apparent at an early date that motion pictures had an international appeal. While the art was still in its inventive stages, films were exchanged between the United States and Europe. At one period





2

SETTING FOR ROBIN HOOD

Two settings designed by Wilfred Buckland for Douglas Fairbanks' production of "Robin Hood." The large simple architectural forms on which the light is projected make an interestingly designed background, and in fig. 1 (similar to Plate V. fig. 2) especially, make the figure appear diminutive by comparison. In fig. 2, the framing, by the arch, produces depth, and a sense of witnessing the action with the figure in the foreground

SKETCHES FOR MOTION PICTURE SETS

1. Sketch of mediaeval Paris by William Cameron Menzies, for "The Beloved Rogue," a film based on the life of François Villon. The aerial perspective is interesting and produces a fine pattern of design
2. Sketch for a motion picture set by William Cameron Menzies; a fine massing of forms to concentrate the interest

the productions made by Paul in England dominated the American market, while the films of the Lumières met a popular reception in the United States. Subsequently, American productions discovered world markets, penetrating even the remote areas of civilization. After story pictures came into vogue difficulties oftentimes were encountered. Types of stories which appealed to the domestic population had the opposite effect on foreign audiences. Producers sometimes met difficulties of this sort in their own countries. The outstanding example, perhaps, is Griffith's *The Birth of a Nation* which, because of its theme, created racial enmities and even bloodshed.

Early in the 20th century great studios sprang up in America, England, France, Germany and Italy, but with the coming of the World War in 1914, the production in England and on the continent was virtually suspended. During the immediate succeeding years, American producers dominated the world market and established themselves so strongly that the freshened production activities in Europe following the World War were unable to dislodge them.

The success of the American producers in foreign fields made evident to them the importance of fostering international goodwill. The stories on which their pictures were based began to show an international flavour. A notable exception to this rule was the case of western cowboy pictures, inherently American, which met with a pronounced success in all parts of the world. The average pictures were designed to appeal to all races, classes and creeds, giving offence to none. Classics of literature were combed for screen material. Historical photoplays not only brought heroic eras to the screen but also exercised a distinct educational effect. Most modern photoplays, however, depict modern life in its multitudinous phases and it is the form of screen entertainment that will in all probability continue dominant in the future. Of recent years there has been a tendency to minimize vice, sordidness, drabness, melancholy and other unwholesome elements in screen plays. Humour in pictures of serious import has become increasingly evident, with a fair proportion of six, seven and eight reel comedies.

The rehabilitation of the European studios closed by the World War brought forth many interesting photoplays, but because of the domination of world markets by the Americans, these pictures did not have as wide a distribution as they might otherwise have enjoyed.

Sound-pictures.—Even before the invention of motion pictures it was the aim of many inventors to combine animated pictures with sound. (*See* Motion Picture Technology, p. 867.)

The years 1928 and 1929 found the major American film studios producing "talking" pictures. The advent of sound on the screen had a revolutionary effect on many phases of production. Electrical and acoustical engineers became important factors at the studios, many sound-proof stages were erected and motion picture players developed voices for what hitherto had been solely a pantomimic art. Installations of sound reproducing apparatus in the principal theatres of the United States were completed in 1929, but inasmuch as the great majority of theatres in small cities and towns were not equipped for the projection of "talking" and sound pictures, it was necessary in many instances to make two versions of each production: one silent and one synchronized with voice and sound. American pictures designed for release in foreign countries (excepting the English-speaking nations) were required to be either silent or synchronized with sounds and music only, due to the commercial impracticability of making dialogue recordings in languages other than English at the American studios.

An outstanding development of the sound pictures is in topical subjects. This is of incalculable value, inasmuch as it permits recording for both present and future generations the images and voices of famous personages.

Colour-pictures.—Coloured motion pictures have long been the goal of experimenters. (*See* Motion Picture Technology, p. 867.)

Ambitious undertakings along this line have been made during the last few years. Cecil B. De Mille's American super-spectacle, *The Ten Commandments,* made use of colour, while the Douglas Fairbanks feature, *The Black Pirate,* was filmed in natural colour in its entirety. A still more recent use of colour was in the Paramount production of American Indian life, *Redskin,* which utilized the technicolor process.

The perfection of equipment that will produce natural colour films with the same facility that governs present day black and white films will in all probability bring about a decided trend in favour of colour pictures.

Projection.—From the early period of motion picture history, when exhibition of films was effected by an operator who carried his projection machine and equipment from town to town, this branch of the art has made strides comparable with those taken by production. Modern projection is accomplished in mammoth theatres seating as many as 5,000 persons. Symphonic orchestras provide music suiting the various moods of the picture, while special stage effects are designed to enhance the presentation on the screen. The early projection machines, which threw a small, unsteady, flickering image on the screen, have been improved to the point where the projected image simulates real life. Auditoriums are designed so that spectators may enjoy an undistorted picture without eyestrain. Hazards from fire due to the inflammable character of the film have been almost completely eliminated by steel or concrete enclosed projection rooms. Multireel pictures made it necessary for the use of two projection machines in order to eliminate a waiting period between reels.

During the last few years greater attention has been given to the creation of special visible and audible effects to accompany the picture. A device known as the Magnascope permits the image on the screen to be increased to several times its normal size, thereby accentuating certain episodes of the picture. This device, which involves the use of special magnifying lenses on the projection apparatus and a screen of threefold proportions, had its first demonstration in the epical American photoplay *Old Ironsides.*

Motion pictures synchronized with dialogue, music and natural sounds have in many instances enriched the literature of the screen. It is now possible to depict certain types of stories to better advantage than permitted by silent films, for the human voice sometimes adds a quality of expression which is impossible to achieve solely with pantomime and subtitles. Many screen stories, however, are most effective when depicted in silence, and in some cases synchronized music and sound effects combine to make the pictorial matter more entertaining than would be the case if spoken dialogue were used. Pictures of the calibre of *Wings* and *Redskin* have a greater appeal as silent films synchronized with sound and music than if they had contained talking sequences. In other words, some screen stories are adapted to the human voice and some are not, and it is necessary to make judicious use of each of these elements if the best results are to be obtained.

Topical Films.—The topical picture now has its greatest manifestation in the news reel, which has grown to be an industry of monumental proportions. The greatest events of the day are shown in all the theatres of the world a few days after they occur.

The incalculable value of the cinema as an educational force is being appreciated more and more. (*See* Educational Films, p. 866.)

A new type of photoplay of recent years indicates still another field for the cinema to penetrate. This is the "nature picture," in which the story is of minor consequence, the players untrained and the sets those provided by nature. *Nanook of the North,* made several years ago and depicting the life of the Eskimos, is a classic example. This picture was made in the Arctic with Eskimos for players and with no story other than that of the lives of the players themselves. *Grass,* the story of nomadic Persian tribes; *Aloma of the South Seas,* which told of the life of island dwellers in the Pacific; *Chang,* depicting the existence of natives in the jungle and *Stark Love,* a story of mountain folk in the southeastern part of the United States, fall into this category.

Camera Magic.—One of the earliest discoveries in connection with the cinema was that physically impossible things could be shown on the screen. Camera trickery, by means of which countless feats of magic could be shown, became part of the cinema's stock-in-trade. The experiments of Muybridge in California were of a scientific nature, but it was not for many years that science

began to make use of this new device. The early topical novelties presented flowers blooming in the space of a few seconds, buildings disappearing piece by piece and inanimate objects moving without human assistance. "Slow-motion" effects gained by the use of super-speed cameras not only resulted in many novelties but also proved of vast scientific value. In the field of medicine, microscopic motion pictures have opened a new field of research. Microscopic slow-motion pictures of surgical operations are being made so that students in remote sections of the country may observe the methods of great surgeons. The X-ray, in connection with the cinema, has been of invaluable assistance in observing the functioning of the human heart. In the field of natural history it has been possible to effect remote control of cameras, and thereby make pictures of wild animal life which could not have been obtained with an operator present. Special diving bells have been constructed which permit the mysteries of submarine life to be shown to the world. Of recent years, through ingenious optical devices and miniature scenes, it has been possible in many instances to eliminate massive settings and backgrounds.

STATISTICS

The tremendous size of the motion picture industry is shown by the following statistics:

It is estimated that in 1925 there were approximately 50,000 places throughout the world where motion pictures were exhibited. These include theatres, auditoriums, halls, etc. Of this number approximately 20,000 are in the United States, compared with 9,000 in 1910. There are 3,500 picture theatres in Great Britain, 2,500 in Latin America, 2,200 in Italy, 4,000 in Germany, 3,000 in France, and the remainder distributed in other parts of the world. In the United States 300,000 persons are identified with the motion picture industry. Approximately 700 feature pictures are made annually in America. It is estimated that 115,000,000 individuals attend the cinema each week in the United States and the admissions paid to see pictures there totals $1,560,000,000 annually. There is a permanent investment in motion picture enterprises in the United States of $1,500,000,000. The United States exports 65,000,000 feet of unexposed negative and positive film each month. The Eastman Company alone produces 900,000,000 feet of raw film annually. In 1925 there were 132 producing organizations in the United States, and these companies invested $93,636,348 in new productions. Salaries of "stars" and featured players are higher than those obtained in almost any other field of endeavour. Purchases of story material cost millions of dollars annually. Productions costing $1,000,000, $1,500,000 and $2,000,000 each are not unusual. The average feature picture costs from $200,000 to $300,000. An average of more than 11,000 persons were engaged in the production of pictures each month.

Exports of American film jumped from 32,000,000 feet in 1913 to 178,000,000 feet in 1924, with a further increase to 235,000,000 feet in 1925. The European market absorbed 17,000,000 feet of this total in 1913, 60,000,000 feet in 1924 and 86,000,000 feet in 1925. Latin America imported 1,500,000 feet in 1913 and 63,000,000 feet in 1925. Far East countries in 1913 imported 4,500,000 feet and 54,000,000 feet in 1925.

American pictures are shown in 70 countries and their subtitles are translated into 37 languages. In 1925 Germany ranked second in world film production with an output of approximately 150 features. Approximately 80% of all feature plays shown in England are made in the United States. France is the second nation in Europe in the importation of American films, absorbing 19,000,000 feet in 1925. Germany has increased its importation of American film from 25,000 feet in 1913 to 6,500,000 feet in 1925. Sixty per cent of all pictures shown in German theatres are American.

MODERN PRODUCTION METHODS

The growth of the cinema in 30 years has brought it to a point where, in order to meet the enormous demands for its product, it has been necessary systematically to organize all phases of production. While the motion picture is essentially an art, the very nature of the ingredients entering into its composition brings it into the class of a vast industry. Whereas, in sculpture, music, painting and other forms of art, the creation is usually the product of one person, the cinema is the product of hundreds and in some cases thousands of individuals. In order that there may be co-ordination of effort it has been necessary to organize production under the direct control and supervision of one mind. The scope of motion pictures has widened to such a degree that the art is divided into many divisions and in all probability always will be.

So great are the sums involved in production that studios are organized on a basis similar to that of large commercial enterprises.

(J. L. La.)

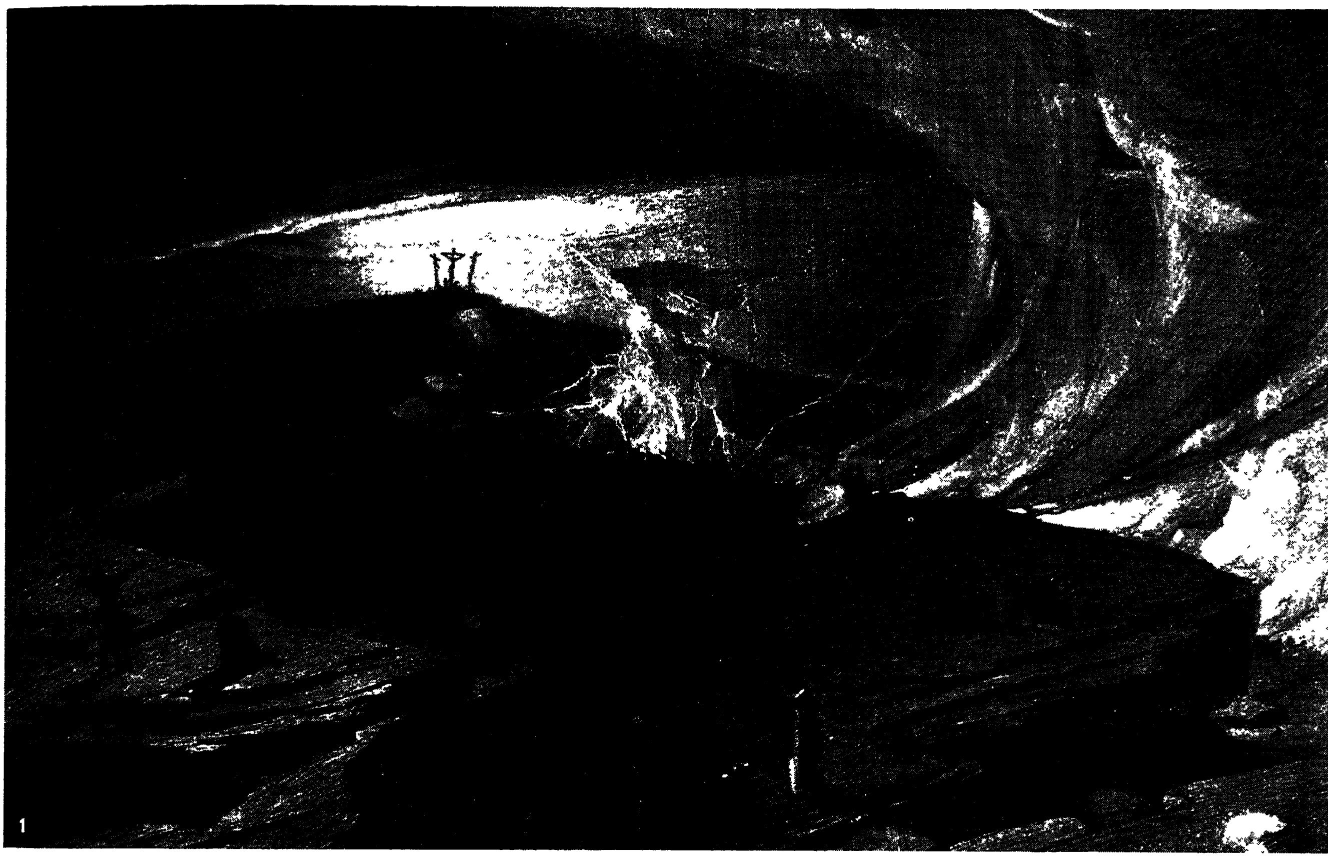
MOTION PICTURE SETS

Motion picture sets constitute the organized settings and equipment that form the environment of a scene that is to be photographed. The first motion picture settings were built on outdoor stages, for natural light was then considered necessary. Later came the glass stages, hung with white and black diffusing cloths that could be pulled over them, as the light changed during the day. The set construction was extremely simple, consisting mainly of "flats" much like those of the stage; *i.e.*, wooden frames over which were stretched linen or muslin in sizes 2′×12′, 4′×12′, 6′×12′, 8′×12′, 10′×12′. All architectural detail was painted, including fireplaces, furniture and the pictures on the wall. Then there came a craze for wall-paper, so that when anything particularly fine was wanted in the way of a set, wall-paper was called in as first aid. The larger the design and the more contrasting in values, the better. Before this mass of conglomerate design, the actor was in continuous competition for the attention of the audience—and often he lost. Until this time the screen world had developed no definite ideas about settings. Anyone, from the property boy up, took a hand at designing them. Scene painters and stage designers, recruited from the theatre, contributed their share, though in many cases the carpenters were given a picture torn from some book or magazine and told to copy it. Eventually, men with some degree of technical knowledge were employed; draughtsmen were engaged to draw the plans; panelling was drawn in detail, and sets then began to take on the appearance of real interiors. Unfortunately they lacked that subtle quality known as good taste, and the draughtsmen, in their endeavour to create a rich man's home, seized upon the more ornate styles of architecture, resulting in an unprecedented riot of ornamentation, weird furniture and fantastic draperies.

Increasing Taste.—From this came a demand for simple and realistic sets, and, quite naturally, the producers turned to the theatre for their designers, Wilfrid Buckland was the first man of recognized ability to forsake the theatre for the motion picture, and to him are attributed the first consistent and well-designed motion picture sets. He brought to the screen a knowledge of mood and a dramatic quality which until then was totally lacking. Following him came Hugo Ballin, a noted mural and portrait painter. Ballin's approach to the problem was that of the painter with considerable architectural knowledge. His settings possessed a simplicity that was most refreshing. He eliminated almost all unnecessary detail, leaving the eye free to concentrate upon the actors and the action of the scene.

Modern settings are almost without exception realistic and architectural. In plan they follow much the same idea as in modern homes, with the exception that all rooms are not necessarily connected. The hall-way is sometimes set up with the living-room, and the dining-room is placed on another stage. The designer depends upon those who cut the picture to establish the geography of the settings. The interior sets usually consist of three sides and are built on indoor stages surrounded by light platforms to carry the lighting equipment.

Problems of Perspective.—A set, as it appears to the casual observer, is much the same as a real interior, with the exception that it is painted in monotones and the mouldings and other breaks exaggerated. The increasing depth of the mouldings and other breaks is to overcome the flattening effect of diffused lighting. The more frequently the wall is broken, either with jogs or recesses, the more interesting it becomes photographically, as it gives opportunity for light and shadow. The primary function of the set is to form a background for the actor. When the set



DESIGNS FOR MOTION PICTURE SETS

1. Setting designed by Anton Grot for the Cecil de Mille production of "King of Kings," based on the life of Christ; a remarkably dynamic design in its masses and use of light
2. Setting by Anton Grot for the de Mille production, "Road to Yesterday," an interesting design similar to Pl. III. fig. 1

REPRESENTATIVE MOTION PICTURE ACTORS

1. Tom Mix, popular star in cowboy and Western-hero rôles, and Eva Novak, in "No Man's Gold," an old-type Western story. 2. Theda Bara in "Salome." 3. Lon Chaney, noted as a portrayer of grotesque characters. 4. Wallace Beery, well known character actor. 5. Charlie Chaplin, famous comedian, and Merna Kennedy. 6. Rudolph Valentino, romantic hero. 7. Douglas Fairbanks, actor of breezy, adventurous heroes in spectacular costume plays, and Dorothy Revier, in "The Iron Mask." 8. Adolphe Menjou, portrayer of sophistication. 9. Mary Pickford, popular in child rôles

becomes more than the background, except in the case where it is necessary to characterize some mood, it is decidedly out of place. To create an appearance of great scale, it is sometimes advisable to increase the size of the detail. For instance, a close-up figure of a man standing at the base of a column 10 ft. in diameter leads the spectator to believe that he is standing before an enormous edifice of which the large column is but a detail. In the picture *Ben Hur,* the Circus Maximus was a setting unlike any circus that ever existed. The designer was confronted by three important problems: It was to be seen, first, in a long shot (photographed at a distance); an impression of great scale was wanted; the imperial power of Rome was to be felt; the spectators were to be treated as part of the design. Second, there was to be a chariot race photographed from practically every conceivable angle. Third, whenever groups of moving chariots were photographed, it must be against some detail so enlarged that the audience would not lose consciousness of the arena's scale. At each end of the *spina* the two crouching figures were about 30 ft. high, so that when the chariots turned, in racing, one recognized their minute proportion in contrast with the enormous detail in the background.

NEED FOR CO-ORDINATION

Buildings as Local Colour.—Unfortunately for the work of the designer, there is considerable reproducing of existing buildings, both in the interiors and exteriors. As the story may wander anywhere over the globe, it can readily be seen that a well-known structure is sometimes needed to indicate a certain city or country, such as the Grand Central station for New York; the Eiffel Tower for Paris; the Houses of Parliament for London. It is good practice, however, to avoid the reproduction of any of these things, and to imagine some more simple means of embodying one's geography. Certainly a plain wall with a few pieces of furniture is not suggestive of any particular country until, say, a Scotchman in kilts walks through. Then we know we are in Scotland. Because of the various production problems, the designer is sometimes given a script and told that the picture must start within a week or ten days. Suppose the scene is mediaeval France and requires, as background, an old castle on a hill and a village at the base. This has to be ready to photograph, let us say, in 15 days, which is by no means unusual time. The designer, then, has little opportunity to give really careful study to the matter of design, though the most important essential of the set is to create for the picture a background of that period. He has practically no time to do anything but handle the general masses and composition. He depends, to a very great extent, upon his knowledge and something that he has at some time half-imagined. All this is thrown almost helter-skelter into a castle and village setting. That the result is as satisfying as sometimes develops, is a source of continual amazement to most designers of sets. However, the best results do not always follow such fast work, and as the production of motion pictures is becoming more smoothly organized the producers are realizing the economic value of proper preparation before the actual photographing of a picture commences.

Technical Detail.—The problem of design is far from being the only one that confronts the set designer, for within a few days' time he may be called upon to lay out and make sketches of a lady's boudoir, the boiler-room of an ocean liner, a modern hotel kitchen, an Eskimo's igloo, a Chinese temple and an African village. Much of this requires careful research. On some of the interiors and exteriors dealing with the present time, it has been possible to introduce some of the most modern forms of architecture, and as these are simple and provide an excellent background, there is no reason why they should not become increasingly popular. They demand a greater inventiveness and consequently less restraint, thus gaining considerable freshness in their visual aspect.

Proper Lighting.—Unlike the stage designer, the designer for moving pictures has seldom the opportunity, to supervise the lighting of his sets. A set is always planned with some particular type of lighting in mind, and because of lack of adequate co-operation on the part of the cameraman, it often appears much less effective on the screen than would have been the case had the lighting suggested in the sketch been carried out. The cameraman claims that primarily he is lighting people, that is, the performers, and that the settings are secondary. This is quite true, but a setting properly lighted will give prominence to the actors. Proper lighting, without exaggeration, is almost equal in importance to design.

The Moving Eye.—It seems that the mobile value of the camera is as yet little appreciated, though more and more it is being moved, even during the actual photographing. This quality of the camera is invaluable in making certain effects convincing, as may be realized when one considers that the camera is the eye through which the audience sees. To illustrate: When the camera is moved from one position to another or is moved during the scene, it is as if in a theatre the audience were picked up and moved *en masse* from one side of the stage to the other; moved closer to certain characters and further away from others as needed for accentuation of certain action. A moving camera gives a stereoscopic feeling that is never obtained with a stationary one. Also we must not forget that the motion picture setting, in comparison with the stage setting, is seen from many more different angles. The camera is continually moved from long-shot to close-up, from close-up to cross-angle. Hence, the motion picture set must be designed to fit an ever-shifting camera, which should be and is of considerable advantage because by this very movement we can suggest a certain sense of plan.

As a good photograph must look like a photograph and not like a painting, a painting should never look like a photograph. Consequently, what is photographed should represent something real or something that may exist; not necessarily something someone has seen or encountered before, but not purely abstract, as has been the case with many stage settings. Generally, a set must be as normal as the characters who people it. It is doubtful if moving pictures will ever develop a particular style of set, as the modern stage has done, because the range of the settings in a single picture usually covers so many more and such different scenes. On the stage, an audience sees with its own eyes; on the screen it sees the set through the eye of the camera. It will accept and believe much more on the stage than it will on the screen. If, on the stage, the door in closing shakes the wall, the audience accepts it and thinks nothing about it; if the same thing should occur on the screen it would be resented as being false.

Interiors.—The designer of screen sets should be a combination of three things—painter, architect and dramatist. The screen set calls for certain architectural principles applied to a given subject. This must be done more with the eye of the painter or illustrator than the eye of the architect. Take, for example, an interior to be used for a nursery. Any architect knows very definitely that the brighter and better ventilated this room can be, the better the nursery, yet when the same interior is demanded for a set, none of these things are taken into consideration. Let us assume that in the story, the child is neglected by its parents, who leave him in the care of nurses. The set must then embody the following: It should be cold in appearance—no warmth or sunlight; the toys scattered about should be too advanced or complicated for the child, or toys which he has outgrown. It should be a playroom in which he cannot play—almost a prison—which presents quite a different problem from that which confronts the architect when he is required to design a real playroom. And so with other interiors.

Architecture is designed to see with two eyes. The camera has but one lens (or one eye) and hence obtains no stereoscopic view of anything. The swelling of a column is, as most people know, to overcome the top-heavy feeling of a straight shaft. For the camera no swelling is necessary for the obvious reason that the column is being seen with one eye. And so on through many other architectural formulae.

Dressing the Sets.—The movement of the camera is so sustained in a picture that it is practically impossible to design so that in each set-up the composition is good. The designer, after a time knows almost intuitively where the grouping of actors will be most effectively photographed. Originally, the director in

photographing his action would start with a long-shot showing the entire setting and all the characters. To-day this is seldom done. The designer pays less attention to the position of long-shots and more to the individual camera positions.

After the set has been designed and constructed upon the stage it must be "dressed," and by dressing is meant the placing of furniture, hanging of draperies, accessories and appointments. In the large studios this is done by the property department under the general supervision of the designer. In the smaller studios, having less organization, the designer must enter into the actual dressing of his settings to a much greater degree. Through some distortion of the lens, a couch placed directly in front of a fireplace in the side-wall would appear to be several feet away. To correct this the couch is placed down-stage so that it does not face directly into the fireplace but faces the wall between the fireplace and the camera. The same applies to a table which is to be made as if it were in the centre of the room. It should be placed much nearer the camera than to the back-wall of the set. On the stage an open foreground is considered an advantage. It has little or no effect upon the appearance of the setting and gives the actors a chance to move about more freely. On the screen the opposite is the case. The foreground should be rather "well-dressed." By that is meant two or three pieces of furniture silhouetted against the setting which give a roundness to its composition and a feeling that there is a fourth wall. In a real interior one enters, sits down, looks around, and soon ascertains whether certain compositions of furniture in themselves are pleasing or not, assuming here that the interior is supposed to be well-balanced, and the composition and design carefully considered. A point usually overlooked is that a "dresser" will attempt to make the set as much like a real interior as possible. In doing this he often has a tendency to overcrowd with furniture, forgetting that a screen set is never photographed, except in rare cases, without the actors in the scene. Hence, allowances should be made in its furnishings for the placing of the actors. The "dressers" of the sets also have their handicaps. They have too little time for careful arrangements and the consideration which most sets require. Only rarely does the "set-dresser" have more than a few hours to complete an assignment. However, more time is allowed in the dressing of exterior scenes such as villages and streets.

Looking Forward.—The future of motion picture set design is problematical. Naturally sets will always be controlled by the type of story produced. In *The Cabinet of Dr. Caligari*, made some time ago in Germany, the story was told in retrospect by an inmate of an insane asylum. Settings seen through his insane eyes were strangely distorted, with leaning walls and painted lights and shadows. They were a rare exception and have had but little effect on the trend of motion picture settings. The best of the modern settings have almost reached their limit in pure pictorial beauty. Whether this type of set will continue to satisfy is a question, or whether, as in modern art, beauty for its own sake will not be demanded. If realism can be abandoned, we may look for a setting which in itself will be as completely modern as is modern painting or sculpture. (C. Gr.)

MOTION PICTURE ACTING

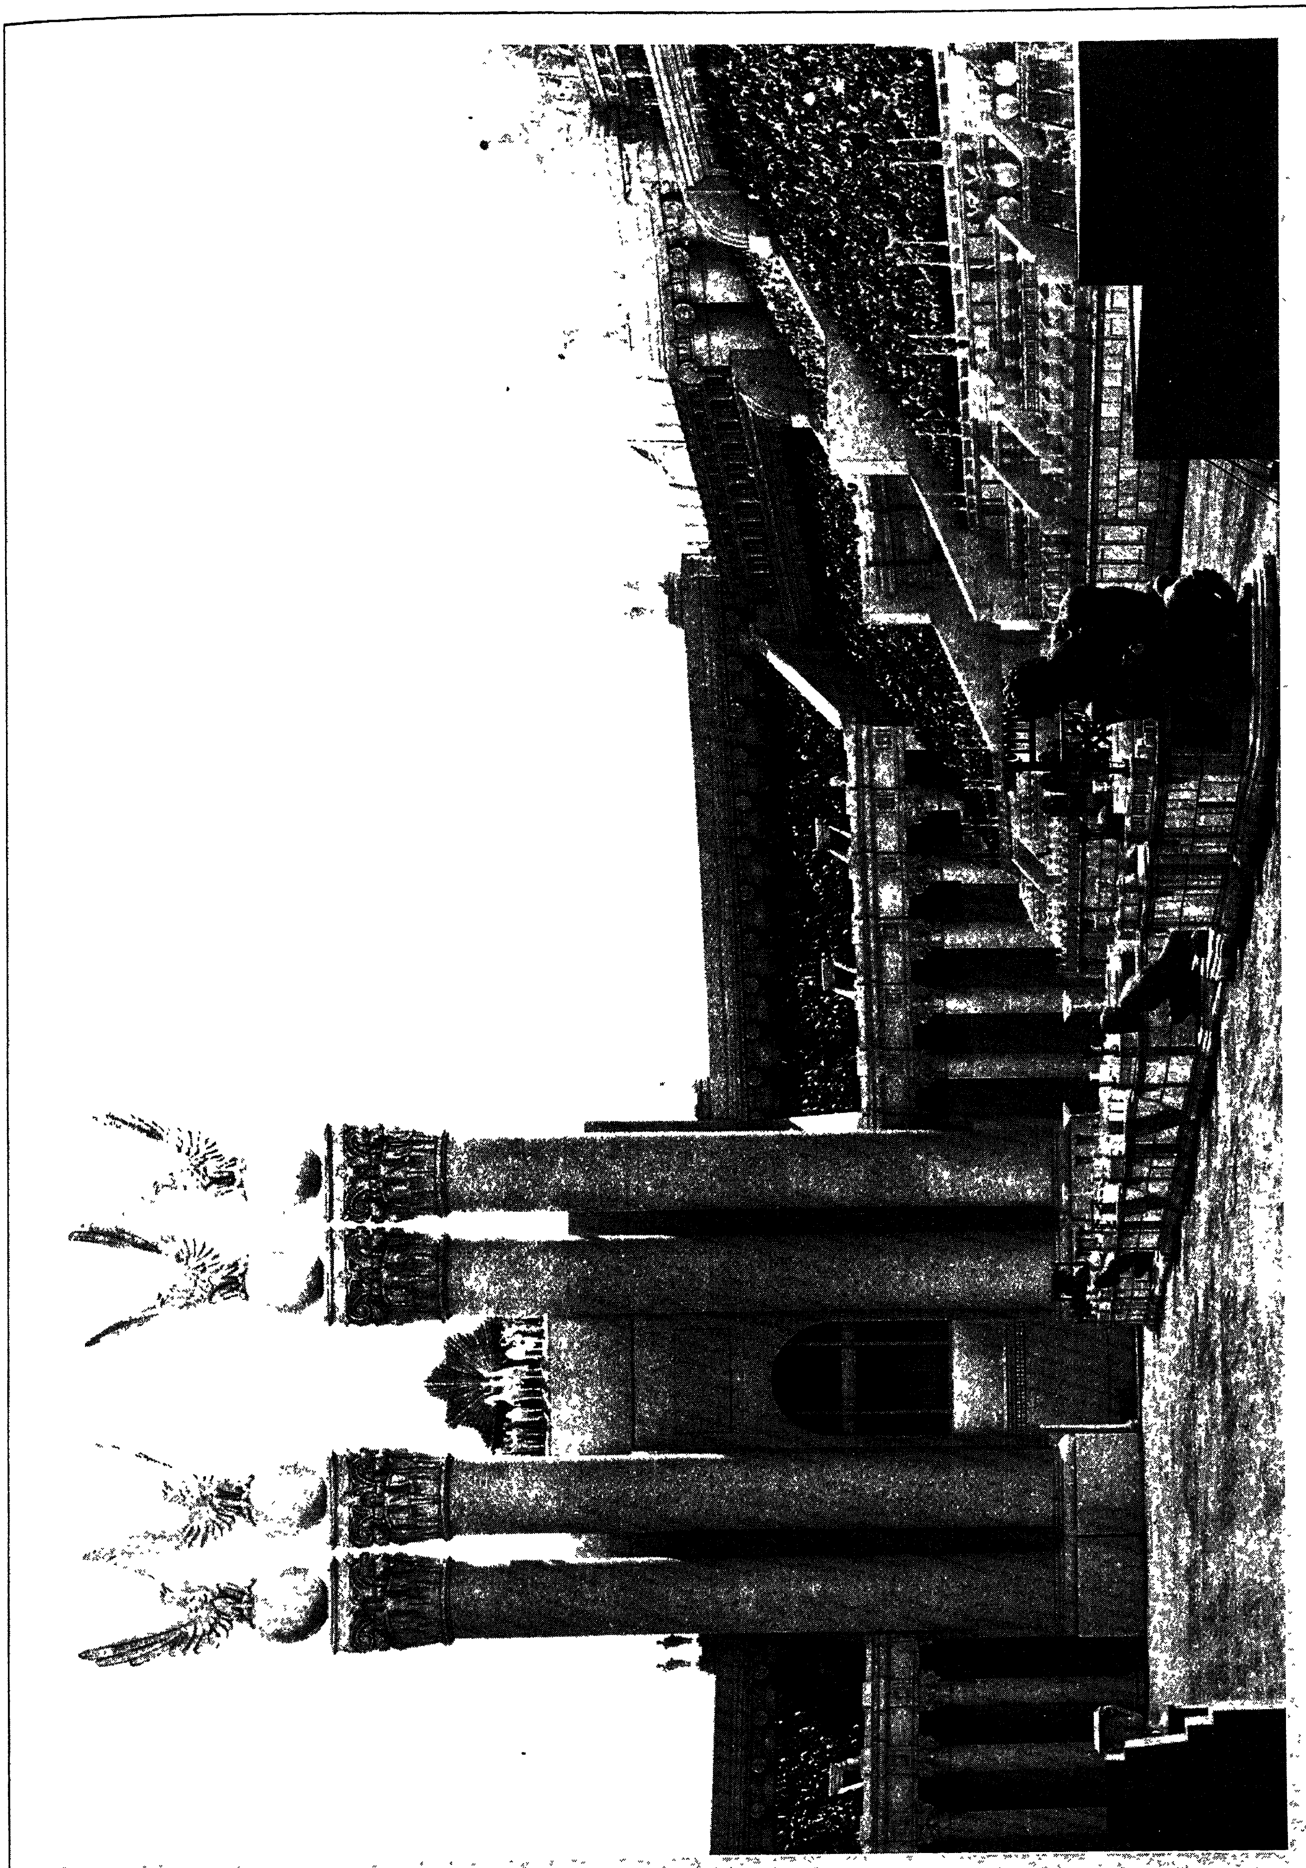
The earliest actors and directors for the screen were drafted from the stage; they carried with them its methods and traditions, translating them as best they could to suit the exigencies of the camera. It soon became apparent, however, that the motion picture demanded a revision in technique. Whereas the stage depended chiefly upon the ear of the audience for the reception of its dramatic message, the screen depended exclusively upon the eye, and it thus became increasingly the problem of writer, director and actor to eliminate as far as possible the spoken word, and to employ visual symbols—facial play, gesticulation and the movement of the body—to express thought and emotion and to envisage the action of the story. In short the motion picture quickly set up as its characteristic medium the inarticulate behaviour of articulate human beings. This prescribed a harsh limitation on acting, automatically suppressing in considerable measure that major portion of our civilized intercourse, speech, and concentrating on its more elemental phases, the dumb grief of stricken women, the silent yearning of youth, the speechless fury or the stunned remorse of men. The motion picture had to reckon with a public, unfamiliar with the hieroglyphics of the film, and with actors so dependent on speech as to be unresourceful in visual symbolism, and easily prone to strain and exaggerate their expression of feeling in an effort to convey it to their audience. Until both audience and actor could be educated to a subtler art, physical action of a broad and even violent character was in vogue. Much of the earlier work of G. M. Anderson ("Bronco Billy"), Maurice Costello, King Baggott, J. Warren Kerrigan, Hobart Bosworth and even William Farnum and Francis X. Bushman, was in consequence crude, obvious and melodramatic. Moreover, many of the earlier players found their way to the screen after having been rejected by the theatre, and for a long period the better class of stage actors scornfully withheld themselves from the temptations of the studios.

The Trend Toward Motion Picture Acting.—It was not until about 1914 that the more competent legitimate actor began to discover the artistic possibilities of the motion picture, and to migrate to that medium. About this time it became apparent that the screen, indeed, lent itself to a very subtle form of expression. The sensitive acting of Henry B. Walthall, in such pictures as *The Avenging Conscience* and *The Birth of a Nation*, bore witness that the mere shadows of hands and eyes could be infinitely eloquent of the more delicate nuances of human feeling. In truth, no subsequent acting has surpassed his in its peculiar fitness for the film. From Mary Pickford also the screen had caught the reflection of a wistfulness and charm that have secured for her an outstanding position. Contemporary with hers, the acting of Mae Marsh and more especially that of Lillian Gish was welcomed for the beauty of its poignant or plaintive, gay or tragic melody. The new notes sounded by these pioneers were soon caught up by their successors. While such actors as William S. Hart and Tom Mix have carried on the old melodramatic tradition, it has been largely relegated to the background, and the outstanding players of recent years have cultivated a more restrained, subtle and realistic art.

Further Technique.—In comedy, Charles Chaplin and Harold Lloyd, superseding John Bunny, Ben Turpin, Roscoe Arbuckle and Mack Sennett, have evolved a highly specialized technique for provoking laughter, based on a philosophic conception that mishaps and misfortunes are the object of social ridicule because they represent human maladjustment to the environment, coupled with Bergson's notion that living beings, when they act like mechanisms, become curiously incongruous. Chaplin, in addition, has intensified his comic effects by the insinuation of a forlorn pathos and a tragi-comic nobility into his stock characterization. He is the clown with the broken heart.

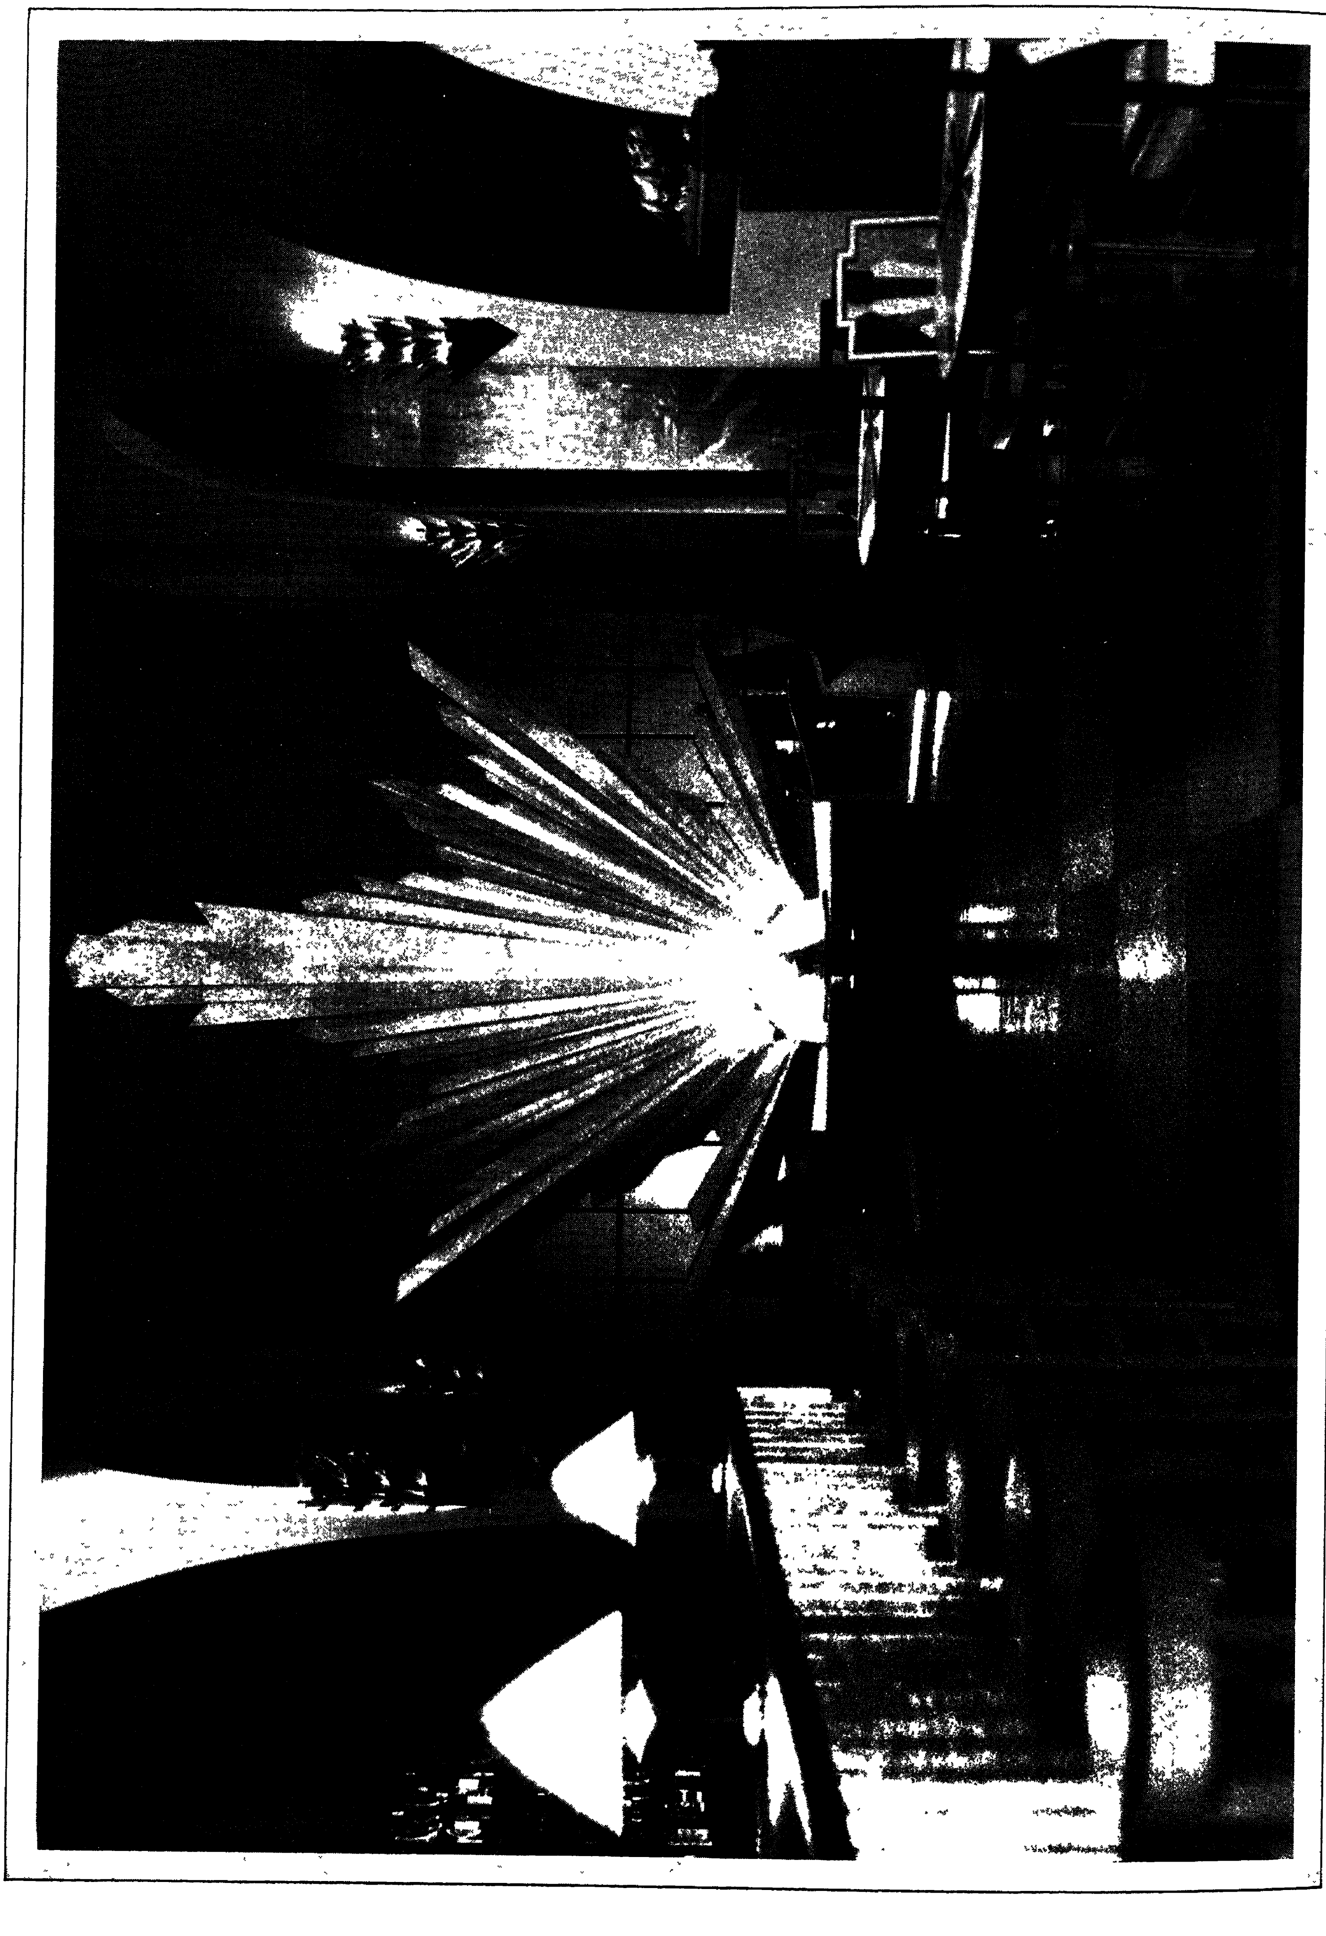
Among the women, Clara Kimball Young, Norma Talmadge, Gloria Swanson and Greta Garbo have exploited the allurements and fascinations of the modern type. Partly owing to a shift in popular interest, they have turned away from the ingenuous heroine of earlier days in favour of the more sophisticated woman of the world. Pola Negri in *Passion* brought a frank realism to the depiction of a woman whose emotions were uninhibited by conventional restraints, and startled the motion picture world by the superb abandon of her tempestuous characterization. In sharp contrast, the more recent portrayal of Janet Gaynor in *Seventh Heaven* suffused the screen with the tender radiance of an indefeasible hope and faith, lyric in its exquisite quality.

In the sphere of character acting the classic performance of Ernest Torrence in *The Covered Wagon* remains memorable for its grim and rugged humour and its graphic force and vitality. Notable also was the work of Lon Chaney and Thomas Meighan in *The Miracle Man*, and of equally outstanding merit were the performances of Richard Barthelmess in *Tol'able David* and of Percy Marmont in *If Winter Comes*. Among the more recent actors who have gained prominence are Adolph Menjou, Ronald Colman and John Gilbert. The epitome of the male flirt, Menjou, by the shrug of a shoulder, a bored half-stifled yawn or the wry



SETTING OF THE CIRCUS MAXIMUS FOR "BEN HUR"

Setting of the Circus Maximus of Imperial Rome, designed by Cedric Gibbons for the Metro-Goldwyn-Mayer production of "Ben Hur"



A MODERNISTIC SETTING

Modernistic bar set designed by Cedric Gibbons for the Metro-Goldwyn-Mayer production of "The Cardboard Lover," suggesting a sophisticated modern atmosphere

cynical flicker of his moustache, can suggest the fascinating wickedness of a calculated sophistication. The more florid and impulsive style of Gilbert's acting suits the reckless, devil-may-care young man, a vagabond among hearts, living in the present and sowing his wild oats, which he so cleverly portrays. Finally, in Emil Jannings the screen finds a master craftsman who, in *Henry VIII., The Last Laugh, Variety* and *The Way of All Flesh,* has evinced a remarkable versatility in characterization. Equally skilled in comedy or tragedy, he is at his best in depicting the gradual physical and moral disintegration of the erring and repentant man. In each of these examples the actor's technique is notable for its expertness in innuendo, suggesting much by little, leaving much to the imagination of the audience.

Present-day Tendencies.—Thus through some 30 years of intense elaboration there has developed a technique of pantomime, which, through the ingenious invention of "business" and a highly skilled use of the new alphabet of gesture and facial play, has learned to spell out much of the complex meaning of modern civilized life. Recently this development has shown signs of slowing up; for some time the art of acting for the screen has remained relatively static; it has made little advance either in technique or in significance. The general tendency has been in the direction of greater restraint and refinement—in a word, toward less "acting," and the dominant ideal has become a distinct realism in style. "Overacting" has always been more apparent on the screen than in the theatre.

In some quarters there is a growing suspicion that the so-called close-up, in which the face of the actor fills the entire screen, has been overworked. The progressive director now realizes that this vice is in great measure due to the circumstance that in cutting and assembling the bits of film taken from varying camera distances, of which the final picture is composed, the close-up can be substituted for long stretches of action in more remote views which are likely to seem slow and tedious. Its function has been to give a speedier tempo to the film and maintain its dramatic tension, vividness and significance; but frequently it has been indulged in at the sacrifice of important histrionic values. There are actors whose work is more expressive at longer range in which the fluent play of hand and body becomes symbolic of thought and feeling. To preserve these values, the director and actor must co-operate in effecting greater artistic economy and concentration of significance in the longer shots.

Future Possibilities.—If in the future there is to be any important change in histrionic method, it seems now that it must follow some new mechanical development. For example, the advent of the talking motion picture may effect a revolution in the fundamental conventional structure of the literary form which now lies at the basis of the film and compel a drastic revision in technique by the reintroduction of the player's voice. Such a development by enlarging his scope and medium may freshen and reinvigorate the creative imagination of the actor. With each producer vying with his fellow for patent rights in sound-reproducing mechanisms, the talking picture seems destined to grow. A complete reversion to the methods of the stage, however, seems neither possible nor desirable. The motion picture talking camera will still possess the advantage of being able to isolate for eye and ear the essential moment of the action, to concentrate vividly on it to the exclusion of all irrelevancies and distractions, and to keep the focus of the drama always sharp. Acting for the screen will continue to be done piecemeal.

STAGE AND SCREEN

The environment in which the motion picture actor works is entirely different from that of the theatre. The sympathetic presence and response of the living audience with its meed of laughter, tears and rapt attention—factors so integral to a stage production—are entirely lacking in the film studio. Its inspiration can never find more than a sorry substitute in the lens of the camera, which must for the actor's imagination become the living eye of the world. Meantime, he is beset by the innumerable distractions surrounding him, the clicking mechanism which so indifferently records his behaviour, the lighting apparatus with its numerous attendants, the irrelevant and discordant noises of his workshop. For all of these he must school himself to utter oblivion. While actually filming a scene, he must learn to catch the director's frequent shouted instructions, undisturbed by their intrusion. Much of his work must be done in real settings, and with all the difficulties of actual nature to contend with—wind, rain, fire, flood, snow, cold, the heat of the desert, the glare of the sun, innumerable physical obstacles with which the actor in the theatre need not reckon. Yet under the most trying circumstances he must remain facile in the expression of the emotion appropriate to the scene. Amid the overpowering fumes and pandemonium of a steel mill, or the tossing of a ship in a storm, he must be capable of tears or laughter, of tenderness or rage, forgetting his external environment and living absorbedly in the inner world of his imagination.

Coming from the theatre to the studio, the actor is at once confronted with two unaccustomed limitations in space and time. The full stage has been his field of action and a half-hour scene to one of two hours its duration. Now he is restricted in his movements to the photographic field and the focal plane of the camera and to the short duration of the film contained in the camera's magazine. A scene can last very little longer than three minutes; most scenes are very much shorter than three minutes. Acting for the screen therefore is done piecemeal, in small bits, each of which represents a shift in the position of the camera, a change of angle for the purpose of following and emphasizing the significant elements of the scene. The actor's art is accordingly an art of flashes, of highlights, a mosaic in which each particle must be a highly polished jewel. He has no opportunity for sustained emotional flight, but must be capable of kindling the feeling appropriate to the rôle on the instant. Moreover, as it requires weeks and sometimes months to film a complete picture, throughout this stretch of time, and in spite of innumerable interruptions, the actor must keep vividly in mind the character he is portraying and develop it in a sustained, smooth and continuous curve.

As for the field of the camera and its focal plane, these of course vary with the actor's distance from the camera lens. Most of his important work is done at a distance varying from 15ft. to 2 or 3 feet. In order to keep within the hypothetical sidelines of his field, he must acquire an expert half-conscious sense at all times of where those lines actually lie, and yet avoid any suggestion of feeling hampered that may interfere with his imaginative concentration on his rôle and his freedom in delineating it.

While the normal speed of the camera in filming a performance is 16 pictures per second, or 60ft. of film per minute, when the picture is projected in a theatre, it is the custom to run it at the rate of 24 pictures per second, or 90ft. per minute. This, together with the fact that the film does not record movement as adequately as the eye, makes it necessary for the actor to adopt a more deliberate *tempo* than that of the stage or of real life. He must learn to time his action in accordance with the requirements of the camera, making it neither too fast nor too slow—a process of education only to be acquired through experience in the studio. The first mark of a novice is the rapidity and jerkiness of his movements, registered upon the screen as blurred and meaningless streaks. Another essential feature of the screen actor's technique is a careful spacing of significant items which constitute the sequence of the scene. One thing and one thing only must be done at a time, and this in a clean-cut and distinct style with no distracting, irrelevant or unnecessary movements. In scenes *vis-à-vis* another actor, although deprived of the medium of audible speech and dependent almost solely on facial expression to convey his ideas, he must never appear to play to the camera, but must be clever in finding occasion naturally to bring his full face to the front. Further, without being apparently conscious of it, he must at all times, in co-operation with the camera-man, play within a prescribed range of lighting most advantageous for composition and pictorial or portrait effect. As the screen magnifies the image of the actor, and brings it intimately close to the audience, the minutest play of the facial muscles, and especially of the eyes takes on significance. In consequence they must be trained to a great yet controlled expressiveness. They are the actor's

most potent instruments. The faintest flicker of a brow or the tremble of a lip may concentrate the quintessence of infinite meaning.

The rapid development of the talking motion picture has created new difficulties for the actor and director. Mechanical limitations make necessary the filming of long scenes without interruption. Long shots, medium shots and close-ups are taken simultaneously by a battery of several cameras, synchronized with the voice recording device. Later the requisite lengths of these various shots are selected and pieced together to form a complete episode. This forces upon the actor a more sustained effort and demands from him an interpretive intelligence in the reading of lines, hitherto required of the actor on the stage.

Another change interesting to note, is that whereas in the silent picture the film is exposed at the rate of 16 pictures per second, in the talking motion picture the film is run at the rate of 24 pictures per second. The habitual method of the silent motion picture actor has always been deliberate and measured. The new form calls for a more accelerated tempo, both in the acting of the individual player and in the direction of *ensemble* scenes. The sense of pace, hitherto left to the ingenuity of assembler and cutter, must now be appreciated keenly by both actor and director during the filming of the scene.

In the new enthusiasm over talking, which has swept through the studios, there has been a tendency to revert to the methods of the theatre. The consequence has been to glut pictures with dialogue at the expense of the values which the silent motion picture has so carefully and laboriously developed. This will undoubtedly provoke a reaction in the other direction. The ultimate result will be the preservation of the old motion picture with the elimination of the printed title and the substitution for it of the spoken word, only where the spoken word is essential for the progress of the drama.

The heavy cost of producing pictures precludes the opportunity for long rehearsals in which to develop and study a rôle: the motion picture actor must be trained in the ability to respond quickly to the director's instructions and execute them with glib facility. His work thus becomes a kind of improvisation. What it thereby loses in finish, however, it gains in spontaneity, vitality and verve. The screen captures the first fresh inspiration of the actor which the player on the stage has frequently a long struggle to recover and reconstruct during or after his period of rehearsals. Finally, the screen actor is burdened with a great responsibility. The film once complete, it becomes changeless and irrevocable; it represents his finished and final characterization, whereas the actor on the stage can continue to develop his rôle through a long series of performances.

Interesting as the screen actor's achievements have been, the art of motion pictures is still a tentative art in its formative stage, feeling its way by trial and error; it yet awaits its Garrick and its Siddons, its Duse and its Booth. (*See* ACTING; PANTOMIME; THEATRE.) (M. Ss.)

Among the more important departments in the studio which combine in the fabrication of the photoplay are:—

Architecture.—This division is one of the most important in the studio, dealing as it does with the creation of the scenes or "sets" used in the various productions. It may be called upon to manufacture replicas of scenes from all parts of the world and all periods of history. This work, under present-day requirements, must be highly accurate.

Costume.—This department has developed into virtually an industry within an industry. It furnishes costumes for oftentimes thousands of players in one production, and these costumes, like the "sets," must be accurate. Their creation must at times be the work of a few days, necessitating the employment of many skilled workers. Many of the smaller studios, because of infrequent demands for costumes, do not maintain this department, but rent costumes from firms engaged in this business. The large studios, however, operate their own departments equipped for this work.

Casting.—The casting division is divided into two groups. The first, which deals with the selection of stars and featured players, is operated by the studios themselves and is in charge of a man trained for this work. The second group applies to the "supers" or "extra" players who are used as "atmosphere." In Hollywood, the hiring of the latter is done through a central casting organization maintained by the large studios.

Research.—Modern production demands a high degree of exactitude in re-creating the life and scenes depicted in its photoplays. Careful research is essential, with the result that comprehensive libraries are maintained where data, pertaining to costumes, customs, scenes, etc., of various nations may be readily obtained. The architectural and costume departments depend in a large measure on the work of the research department.

Scenario.—Specially trained writers well versed in the technical phases of picture making comprise this department. Before a photoplay can be made it is necessary to have a scenario and continuity which divides the play into separate scenes. In most pictures, many individual scenes are made on the same "set." For economic reasons it is customary to film all such scenes before proceeding to another "set" irrespective of the continuity of the scenes in the picture. In cases where stage plays or novels are used for photoplay material, the scenario writer must make a comprehensive "treatment," translating spoken or written drama into terms of pictorial drama.

Editorial.—Inasmuch as it is usually necessary to photograph individual scenes several times in order to get the desired effect, a completed photoplay usually runs to many times the length in which it is seen by the public. The task of eliminating these surplus scenes is done by technicians specially trained for the work. It is their business to arrange the multitude of scenes into a smooth, logical and pleasing continuity. Other specialists prepare the captions or titles for the production. Unique effects can be obtained in the cutting of a picture, and so important is this field that many photoplays have been made successful or ruined in the process.

Laboratory.—The millions of feet of film consumed in the making of photoplays annually makes necessary the operation of large laboratories at many studios. Here the negative film from the cameras is developed and the hundreds of positive "prints" produced. The work is of a highly specialized nature and exceedingly important.

Electrical.—Sunlight is no longer essential as a source of light in motion picture work. Electricity has so completely superseded the sun that only exterior scenes depend on it for illumination. Various types of arc and mercury-vapour lights have been in general use for more than two decades. Because of the expense in the operation of large batteries of such lights and because of the ever-present danger of injury to the eyes of the players who work before them, experiments have lately been conducted with incandescent lamps. The success resulting from their use has brought about a more general application and to-day several studios are using incandescent lights almost entirely. Incandescent lamps, which are noiseless in operation, are essential in filming scenes for talking pictures.

Camera.—The photographing of modern photoplays lies in the hands of expert technicians well versed in the ways of cinematographic magic. Recent years have brought new qualities of pictorial art to the screen which have been made possible not only through the perfection of the raw film and lenses for the camera, but through the artistry of the camera-men.

Sound.—The sound department, where the delicate apparatus which records the voice, music and sounds for talking pictures is situated, has become one of the most important in modern motion picture studios. The highly technical work of sound recording and its associated processes, such as developing, printing and cutting of sound film, is in charge of experts. (J. L. LA.)

MOTION PICTURE DIRECTION

The Director.—The director of to-day has evolved from the crude stage-manager of the early school of pictures. His business, originally, was merely to move the various characters so that they did not hide one another from the camera and to see that important action was so placed that it registered in the lens.

WELL-KNOWN MOTION PICTURE ACTORS

1. John Gilbert, popular romantic actor, as Vronsky, and Greta Garbo, as Anna Karenina, in "Love," the film version of Tolstoy's novel "Anna Karenina." 2. Norma Talmadge, noted for her emotional acting, in "The Woman Disputed." 3. Ronald Colman, leading man, and Vilma Banky, romantic heroine, in "Two Lovers." 4. Gloria Swanson, popular actress of emotional parts, in "Sadie Thompson," the motion picture version of "Rain." 5. Lillian Gish, well-known for her portrayal of pathetic, ingenuous characters, and Lars Hanson in "The Wind." 6. Janet Gaynor, leading woman, and Charles Farrell, leading man, in "Seventh Heaven." 7. Pola Negri, portrayer of exotic, emotional heroines, in "The Woman from Moscow." 8. Emil Jannings, powerful character-actor, in "The Sins of the Fathers." 9. Milton Sills, actor of virile hero parts, in "The Barker"

DIRECTION OF VARIOUS TYPES OF SCENES

1. Directing an automobile close-up. The camera is attached to the front so that the picture may be taken while the car is in motion. Malcolm St. Clair, directing Richard Dix and Gertrude Olmsted in "Sporting Goods"
2. Directing a street scene. Sam Wood, director, standing by the camera is grouping the characters preparatory to "shooting" the scene. A piano is played during the action to help place the actors in the desired mood. Music is frequently used by directors for this purpose
3. Directing a close-up love scene. John P. McCarthy is directing Eleanor Boardman and Lawrence Gray in a scene for "Diamond Handcuffs." The close-up is used in many ways by different directors, its basic dramatic purpose being to bring out the significance of a given moment by focussing attention on the thought or emotion of given characters
4. Directing a small group in an outdoor scene. The problem of group direction is to keep the picture at all times well balanced although it shifts and changes its form at every instant. Harry Beaumont is directing a bridle path scene for "Dancing Daughters"
5. D. W. Griffith, director, and his technical staff during the filming of a scene for "The Drums of Love"
6. Directing a scene in an outdoor set for the German picture "Schuldig" (Guilty)

His art has developed as the other arts contributing to the motion picture have given him a more sensitive and complicated instrument upon which to play. The greater the number of arts and crafts which combine in picture making the more complex and difficult becomes the work of the director. The very nature of the director's position makes him a co-author of the work. The script of a picture play cannot be as complete as the manuscript of a stage play, since the very detail of movement and business which the director is called upon to supply, corresponds to the lines of dialogue in verbal drama. The script of a photoplay is not a motion picture; it is a blue print from which the picture will be built. The director's function may best be explained by considering the relationship of the various arts which combine to make a motion picture; and by the limitations of the fixed budget for his picture.

The Scenario.—The first element, the story, may be an adaptation from a play or a novel, or it may be an original story conceived and written for the screen. In the latter case it does not have to undergo the difficult process of adaptation which is necessary in the case of a work made for another medium of expression. There are three distinct steps in the creation of a scenario, and a different writer may handle each step: the writing of the story itself; the "treatment" or rough outline of the screen play as adapted from the story; the "continuity" or detailed scene by scene script from which the director actually makes the picture. This last form of writing calls for a high degree of technical screen knowledge on the writer's part, and it is with this phase of the writing that the director is most closely associated. He must work with the writer in balancing dramatic values of individual scenes so that the picture may have true dramatic progression. This must be carefully worked out beforehand for the problem differs from that of a play in the theatre in that each portion of the picture must be finished before another portion can be made, and changes to balance the complete work are most difficult to make after the scenes have been filmed. Unless the director has a clear idea of the contextual value of each scene he is apt to over-develop one portion of the story and find himself without sufficient "footage" left to develop adequately the part which follows.

Motion picture scenarios may be roughly classified under two general headings: the master-scene script, which tells the story incident by incident, but does not indicate division into camera shots, and the "camera continuity," which gives in exact order every camera scene in the picture. It is a matter of choice which type of script is used. For the most part, master-directors prefer not to be too closely prescribed for in the matter of handling their cameras; they like to leave a certain amount to inspiration, to the "feel" of a scene and that spontaneous conception of a moment which frequently occurs when a scene's physical elements—the set, the actors and the lights—are assembled for the first time.

The Set.—In his relation to set design, the director usually confers with his scenic artist and gives him a general outline of the dramatic values which are to be emphasized and the atmosphere which will harmonize with his directorial treatment. He then studies preliminary sketches with an eye to the general movement of masses and individual characters. Special effects are discussed with the art director and the technical department, and at these conferences it is decided what methods are to be used: whether a given set will be completely built to full scale, or whether it will be partly built in miniature or painted on glass and so photographed as to create the illusion that the spectator is seeing a vast building which towers hundreds of feet in the air, when in reality he is looking at a portion of a building, a bit of miniature and a painting. The method of multiple exposure is also used to create illusion, trick effects being sometimes combined with normal exposure; a real ocean scene may be photographed around a ship built on the stage. It is the director's business to see that all these highly technical and pictorial effects harmonize with and carry on the dramatic progression of his story.

The wardrobe department of the studio plays an important rôle, especially in cases where thousands of costumes have to be made, with due regard to the camera values of colour. In productions dealing with contemporary life the dressing of each character becomes a part of characterization, and care is taken to see that each costume is not only true to type but harmonizes dramatically with the scene in which it plays.

Photography.—Next to the writer, the director's most important collaborator is probably the photographer. Good photography adds immeasurably to the director's work and inadequate photography may render it useless. Once the scenario is written, the camera-man becomes the director's interpreter in the matter of atmosphere. The director composes and draws the picture, but it is the camera-man who paints the drawing. He must understand the dramatic colour of each scene, and by the use of lights, lenses and exposure create upon the film the atmosphere of gaiety or gloom, of reality or fantasy; the hot glare of African sand, or the cold glare of Arctic snow. Camera-men vary in individual style as widely as do painters on canvas, and while it is usual for the director to set his "camera-line" and compose the picture, he is quite dependent on his photographer for texture, focus and the quality of the photograph.

Lighting.—Matters of lighting come largely under the jurisdiction of the camera-man. The lighting of motion pictures has made tremendous strides in the last few years. The raw sunlight of early days has given way to the carefully balanced and diffused lighting of the studio. Broad strokes are painted with sun-arcs of over a million candlepower, delicate effects sketched in by incandescent lamps. The direction of every light is arranged so that an effect very nearly stereoscopic is achieved. Many sets are built with a view to special lighting, and, frequently, a set could not be shown except when lighted as planned by the scenic artist. Thus a set may be planned for various planes of light; planes of shadow alternating with or crossing brighter planes, so as to give great depth to the picture and overcome the flat effect which a too evenly lighted set is apt to have.

In handling large sets and masses of people the director does his grouping in connection with the scheme of lighting, working his people through planes of brightness and of shadow until the effect of a great painting is attained. So far has the art progressed that the modern tendency is to do away with tinting the film, effects of colour being achieved by lighting alone, and to-day it is not unusual to photograph an entire picture without the use of make-up on the characters.

Acting.—The element of acting is obviously of vital importance to the value of the photoplay, and it is an element which comes most closely under the director's control. He not only chooses his cast with great care that each part is suited to the actor, but he has much to do with the actor's performance. He controls his actors as the conductor controls the instruments of his orchestra. His function is not to teach acting any more than the conductor's is to teach his musicians how to play their instruments. But he must co-ordinate character conceptions so that each may stand in relation to the other as the story's true development demands. There is constant temptation to let an interesting character become too important for the proper story value of the moment, to over-emphasize a part in its relation to the whole. Careful contrasting of types, balancing a cast, harmonizing and moulding the conception of his characters until each is perfectly adjusted to the dramatic mechanism of which it is a part, are among his most delicate and most important duties. In his relation to the actor, the director must study the individual personality and method of each player and, if he is wise, he fits the part to the actor as much as he fits the actor to the part; he must, to some extent, vary his method to suit the need of each actor, if he is to attain the greatest result of which the actor is capable.

Technique.—In general, the director faces this problem: to perfect each moment of the story separately and then to combine these bits into a smoothly flowing drama in which every moment will bear its proper relation to every other moment. In this connection, the question of *tempo* becomes most important, for the *crescendo* and *diminuendo* of drama are partly achieved through the varying *tempi* of successive scenes. Here again, the

analogy of the motion picture to the symphony is close. But the director is powerless to control the speed at which the picture is projected in the theatre, and his carefully done work is frequently hurt by being run so fast as to lose all semblance of human life.

Another major point in the technique of direction is the determination of distance from the camera to the focal point of interest. It is no easy task to arrange that, as the composition of the picture changes from moment to moment, the spectator's eye is naturally drawn to the particular object which is, at that instant, the most important part of the story. It may be one man's face in a group of 50; it may be the turn of an eye or the massed movement of 1,000 men, the ticking of a clock or a distant bugle call—in each case the object of greatest dramatic significance must be the most visible thing upon the screen. This is the true art of telling a story in pictures, the juxtaposition of different scenes being no less important than the composition of the scenes themselves. When the story action is being carried forward by the movement of characters, greater distance from the object is required than when the significant action of the moment is the thought transition of a single person. The physical aspect of each salient point in a train of thought must be so photographed that when the various pictures are arranged in proper succession the whole thought progression is revealed clearly and smoothly. A dramatic progression may consist of the mental action and reaction of several characters upon one another. To keep dramatic progression flowing smoothly the continuity may flash quickly from one man's face to the hands of another and thence to the tapping foot of a third; or to express in picture the essential thought of a given moment the camera may show the whole figure and then sweep up to concentrate on the face alone. Detail of photographic continuity may be suggested by the writer, but it is essentially the director's function, as the actual placing of the camera with respect to the object is vitally important in its dramatic effect. The most effective distance varies greatly according to the delicacy of the thought to be expressed. In a large close-up the movement of an eye can tell volumes; two feet further away from the camera this movement would be ineffective if not lost entirely, and the thought would require broader movement to express it.

This feeling for line and distance is as important to the director as touch is to the pianist. Frequently distance is varied without actually moving the camera by using lenses which magnify the object and seem to bring it nearer. Thus a lens of two-inch focal length (the normal lens of the average picture) may be set side by side with a three-inch lens and a four-inch lens. If all three cameras are 12 ft. from the object the three-inch lens seems to bring the object to a distance of 8 ft. and the four-inch lens brings it to within six feet. In this way difficult scenes may be photographed simultaneously from various angles and different distances. The large close-up is used in many ways by different directors; its basic dramatic purpose is to bring out the significance of a given moment by focussing attention on the thought or emotion of a given character; to record his transition of thought or to separate him from the group of which he is a part.

Grouping and mass movements are most important and call for the highest degree of directorial skill, for the picture should at all times be well-balanced although it shifts and changes its form at every instant. To move a group while shifting the dramatic focus from one character to another and yet to preserve good composition in the whole is no mean art. In large mass movements the director has many assistants who take command of a half or a third of the entire mass; under each assistant are several trained actors, each being responsible for a subdivision, and under each of these actors is a group of extras who form the body of the mass. This method of subdividing direction and responsibility gives variety to the mob and tends to avoid the old-fashioned automatic crowd, so familiar in early days.

Assembling and Editing.—The director studies in the projection room the results of the previous day's work, and learns what values he actually has upon the screen; values which frequently prove to be quite different from what he thought he had. He is thus enabled to correct mistakes and retake such scenes as may be necessary.

As the picture progresses it is assembled in a rough cut which corresponds to the first draft of a play. Every scene and incident is in this first assembly, which almost invariably runs from twice to four times the length of the finished product. But in studying this rough assembly the director gets the "feel" of his picture; he senses its length and *tempo* and, frequently, changes his idea of its relative values. He guides himself accordingly in that part of the picture still to be made; he sees that certain incidents are less effective in their context than they felt when they were being made; that others are capable of further development than the first outline indicated; and so, sometimes groping his way, sometimes with true inspirational vision he finishes the "shooting" of the picture.

Then follows the task of editing the film; of reducing 30 reels to ten; of seeing the picture for the first time concretely, as a whole; of studying the new values which inevitably appear and, frequently, of compensating for values which seem to have disappeared. In the process of shortening the film captions must be rewritten, some left out as unnecessary, others put in where action has been so changed in the cutting that it is not sufficiently clear in pantomime alone. The importance of the cutting-room can hardly be overstated; it is here that the director selects and proportions the elements of his picture until its final form is achieved.

In the last analysis the director is a story-teller. His must be the art of combining the arts of others into one creation, and he must balance the values contributed by those other arts so that none of them is out of proportion to the true symmetry of the whole. He may not have conceived the story first, but he has to make it part of himself before he can put it on the screen; he may not have written it, but it is he who tells it; and upon the force, the clearness and the art of his telling depends the value of the work. (C. B. DeM.)

MAKE-UP

The need of make-up in motion pictures was evident from the beginning, but few of the principles of stage make-up could be applied to the new art. Actors found that the make-up of the stage appeared in films in a vastly different way. Red, orange and brown photograph as black or nearly so; blue, pink, yellow and mauve photograph as white. Pink cheeks became a dirty grey, gold fillings in teeth appeared as black specks; freckles "picked up" more black than the eye could see; disguises applied after the stage fashion became, under the merciless eye of the camera, ludicrous. Actors, in experimenting with different colours, found that pinks with bluish tones photographed better, and to-day some stars use a make-up that appears purple. Women, especially, found that applying the laws of photography to their make-up enabled them to correct defects in their faces. For instance, many actresses paint the upper eyelids green, which photographs as a light grey, and tends to make eyes that protrude slightly recede. Double chins can be partly obliterated by a tint of red, which, photographing in a darker tone than the rest of the face, places the offending chin in an apparent shadow. Red under the nose casts an optical shadow, and various colours are used about the eyes to make them appear as desired on the films.

These first make-ups, of course, were achieved by the use of the grease-paint and powder of the stage. But on the stage such make-up is worn only a short time; in films the actor has to wear it all day. Perspiration, dust and great activity before the camera made necessary frequent renewals of the grease-paint make-up. Cosmeticians began experimenting to find combinations that would last longer. Liquid make-up was devised, in which the colouring pigment was suspended in a solution containing a gelatine-like material. This make-up was found to require less patching or repairing. Later a gelatinous make-up was developed, containing materials rich in violet, which requires less light to photograph. The invention of the panchromatic film gave a greater latitude to the camera in dealing with colours, thus permitting the natural face to be filmed, and eliminating the "straight" make-up, which

THE TECHNIQUE AND EFFECT OF MAKE-UP FOR THE SCREEN

1, 2, 3. Stages in the process of making up a young actor, John Mack Brown, for the part of an old man

4, 5, 6. Three poses of Mary Philbin, showing the striking differences effected by make-up: (4) as Dea, the blind girl, in "The Man Who Laughs"; (5) without make-up; (6) as the little slavey in "Stella Maris"

7, 8. Emil Jannings as the Russian aristocrat in "The Last Command," and in "The Last Laugh," showing two completely different facial outlines and types, produced by skilful make-up

9. Conrad Veidt as Gwynplaine in "The Man Who Laughs." The make-up was effected by false teeth, false eyebrows and a wig

is designed to allow the face to be more readily photographed. To-day men use little or no make-up for "straights," and women use a make-up which tends to bring out the good points of their faces and hide the poor ones, but in both cases the make-up is much simpler than ever before. With a knowledge of the fundamentals of stage and screen make-up and the many possibilities in the use of various paints and pigments, it remains for every screen actor to study the anatomy of his own face in order to appear "natural" before the searching close-up of the camera. The following instructions should be kept in mind for practical make-up.

METHODS OF MAKE-UP

Materials Used.—The necessities for make-up are: cold cream; grease-paint or liquid "ground" colours, graded from No. 1, a very light pink, to No. 13, a very dark brown, with No. 14, lavender, and No. 15, white; lining pencils, in black, brown, grey, blue, green and red; powder, ranging from white to olive; rouge and lipsticks, in four shades of red; starch or aluminium powder for whitening hair, also liquid colourings and brilliantine; nose putty; plasto, or undertaker's wax, for building up face, and collodion or "new skin" for scars; gutta-percha, black wax and white enamel for teeth; spirit gum and crêpe hair.

Straight or Foundation Make-up.—Apply cold cream, then wipe it off, to fill pores. Put on "ground" colour, grease-paint or liquid, and spread evenly, fading to nothing at nape of neck. After make-up for eyes, nose, etc., suggested below, powder thoroughly with lighter shade than "ground" paint, as it darkens when dry. To remove the entire make-up, apply plenty of cold cream and wipe off with towel.

The Eyes.—Shading is done with blue or violet lining pencils for soft shadows. Some use reds or grey-greens to shade blue or grey eyes. Black can be used, but with extreme caution, shading gradually to the eyebrows. For the eyelashes, women especially use mascara or sometimes a heavy black grease-paint.

The Nose.—A broad nose may be narrowed by drawing a high-light down the ridge of the nose with light paint, shading with red at the sides to determine the contour. Small nostrils are widened by inserting red around the edges, and large ones can be narrowed by high-lighting the same way.

The Lips.—Work the "ground" colour well into the edges and reshape with lip rouge, making corners come to a point. A small mouth can be enlarged by extending the red beyond the corners, and vice versa.

Hints on Character Make-up.—Shaping the nose, building up the cheek-bones, blotting out the eyebrows and making the eyelids heavy can best be accomplished by the use of putty or plasto wax. To puff out the face, cotton wool is often inserted between the teeth and the cheeks. This material is also used for making bags under the eyes. Cut into a crescent shape, affix with spirit gum and paint over, mixing a little olive oil with the paint. To broaden the nose, negro style, cut three-eighth inch ends of two rubber cigar holders and insert into nostrils. For scars, brush on collodion, which draws the skin; apply a second coat for deeper scars. To remove, add more collodion to soften the scar, then peel it off. For very old age, a thin coat of putty can be applied to the face and lines graved into it with a sharp point for criss-crossing deep wrinkles. Trace the lines with red water-colours. Do not line the eyes. Make shadows with colour a little darker than the foundation, and where face would sink the most make the shadow darkest, always keeping the anatomy of the face in mind.

For Chinese make-up use bits of library mending tissue to draw back the corners of the eyes, thus giving a slant to them. Cover with the "ground" colour, and then paint the eyebrows with an upward tilt. A number of light black lines downward from the inner corners of the eyes and upward from the outer corners accentuate the slant.

False teeth can be made by fitting dental rubber over the natural teeth, carving the sort of teeth wanted on this and painting with tooth enamel. False beards should be made with crêpe hair a little lighter than the natural hair. Comb out well, press in a book, cut off a straight edge, and after applying spirit gum on the face attach the straight edge to the face, and trim with scissors to the required shape. To grey the hair, apply starch or aluminium powder. The latter is better but much harder to wash out. "Polished brass" bronze powder, sold by paint stores, will "blonde" a brunette.

For the negro in film make-up use medium-brown grease-paint, not burnt cork. Cover the lips with the "ground" colour, and build them up with cotton or false teeth from the inside. Do not use a wig, but clip the hair and cover the head with a brown grease-paint. (*See* MAKE-UP.) (L. C.)

A UNIVERSAL LANGUAGE

The motion picture, by virtue of its intrinsic nature, is a species of amusing and informational Esperanto, and, potentially at least, a species of aesthetic Esperanto. Of all the arts, if it may be classified as one, the motion picture has in it, perhaps more than any other, the resources of universality. Even a simple waltz by Johann Strauss may remain alien and unassimilable to the musical ear of the Chinese; a Michelangelo fresco may fail to impress its significant beauty upon a Japanese or Hindu; a drama by Ibsen may remain completely unintelligible, even in competent translation, to a maharaja of India, just as Chinese music must ever remain strange, peculiar and incomprehensible to the Anglo-Saxon ear. But the motion picture art of Charlie Chaplin will inevitably make a Japanese laugh as heartily as a Dane.

The reason is simple. Pantomime is the aboriginal means of human communication and intercourse, and pictures bring to a child his first acquaintance with and understanding of the world about him. The motion picture, combining the two, is thus addressed to a common human understanding. It begins with the elementals of human perception and comprehension; it starts at the outset with the advantage of the fundamentals of human intercommunication and explicitness. It is for this reason that the moving picture has spread through the world and has been accepted far and wide in what has seemed an unbelievably short space of time.

The motion picture tells its stories directly, simply, quickly and elementally, not in words but in pictorial pantomime. To see is not only to believe; it is also in a measure to understand. In theatrical drama, seeing is closely allied with hearing, and hearing, in turn, with mental effort. In the motion picture, seeing is all—or at least nine-tenths of all.

This, of course, is the screen in its fundamental aspect. This is the motion picture simple and unsophisticated. This is the universal *engine* that is the cinema. The motion picture, plainly enough, in certain of its manifestations may remain largely vague and ambiguous to a people alien to the source of its imagination, preparation and making. But the motion picture in itself and in the aggregate is based upon materials of easy, common appreciation. Love, hate, desolation, despair, joy, ecstasy, defeat, triumph—these are universal emotions. Conveyed by words, as drama conveys them, they may offer difficulties to remote and various peoples. But conveyed by the movements of the human face and body, by smiles and tears, troubled brows and dejected shoulders, sparkling eyes and fluttering hands, they are immediately recognizable. A laugh or a sob is the same the world over. They need no words to explain them.

In another phase of the cinema, the so-called news-reel has already proved itself to be a form of journalistic Esperanto, just as the so-called educational moving picture has shown itself to be a form of informational Esperanto. The news-reel has brought to the far corners of the earth the life and daily activities of all nations and people. The educationals, as they are known, have acquainted the audiences of the world with various phenomena associated with invention, manufacture, discovery, ingenuity and enterprise peculiar to a certain country. The news-reel has informed every country of its neighbour, his leaders, his achievements, his troubles, his pleasures, his problems. It has spread a direct acquaintanceship with alien lands, peoples and customs to other lands. It has provided an international newspaper self-adapted to the understanding of all peoples, and a running commentary on contemporaneous history.

The motion picture is at once the common story-book, news-

paper and text-book of the 20th century. In its loftier aspects, it may conceivably elude the comprehension of audiences remote from its birthplace. That is, when it abandons its more elemental nature and strives for isolation as an art form. But that is the fate of art, all art, wherever it be found. Art is for the few, unfortunately; the generality of people have difficulty in taking it into their understanding. Shakespeare and the Orient may remain strangers; Leonardo and Dostoievsky may find no sympathy and hospitality in the consciousness of half a dozen lands. But there is probably no land where the spectacle of soldiers marching off to war or a fat man being struck with a custard pie is not instantaneously hailed with understanding. It is in *elementary* excitements and humours such as these, together with the thousand and one others that they connote, that the motion picture, reaching constantly after higher things, finds the mainspring of its wide and comprehensive appeal. It deals for the most part with primitive instincts, primitive impulses, primitive human peace and alarm, happiness and ache, ambition and dream. These may be dressed in strange costumes and may be shown through strange peoples, but underneath they are the emotions and inspirations and trials of all the human race. The backgrounds may be unfamiliar, but the hearts that beat and struggle, triumph or fall, are the hearts of all mankind. And so the world laughs with Chaplin and Lloyd, cries with Seastrom and Murnau and Griffith, startles at the revelations of Eisenstein, gasps pleasurably at Fairbanks and Valentino, feels tenderness with Mary Pickford and warms to the homely lovableness of Wolheim and Beery. (L. GI.)

EDUCATIONAL FILMS

The United States.—The term "educational" has been commonly used in the motion picture industry to describe all pictures not made for recreational purposes or of an informative nature that may be employed by social organizations as aids to their aims and interests. Religious and historical drama and pictures of travel, science and industry have been thus classified.

Among the first educational motion picture productions was the *Passion Play,* a religious and historical drama filmed in 1898. Its use in religious services by a well-known evangelist introduced motion pictures for purposes of propaganda. *Tearing Down the Spanish Flag* was an historical drama which expired after the Spanish War. Brief pictures of troops taken by camera men during the Spanish War were the prototypes of the news weekly. The news weekly came on the screens of the United States in 1910 when Pathé Frères of Paris circulated a weekly issue of their Pathé Journal. The American edition was the Pathé News. One of the first scientific pictures was exhibited about 1902 by Charles Urban of London. Other products of European laboratories shown in enlargement, with slow or arrested motion, included subjects such as the growth of plants, the emergence of the butterfly from the caterpillar, the crystallization of chemicals and other processes. Treated as "fillers" in theatrical programmes composed of dramas, comedies, serials and news weeklies, they soon drew attention to the value of this new medium of expression as a teaching aid in schools. The animated drawings invented by J. R. Bray in 1911, provided a new means of indicating places on a map and of showing processes that could not be photographed.

Stimulated by this interest, the Motion Picture division of Thomas A. Edison, Inc., Selig, Essanay, Universal and other companies invested heavily in educational pictures. Charles Urban, George Kleine, Pathé and Gaumont, imported French, British and Italian films.

In 1912, the General Film Company distributed pictures made by the most important American producers and in the educational department of this company were assembled a large collection of educational films.

Between 1915 and 1925 some seven companies were organized to produce and distribute educational films for schools, churches, clubs, public institutions and industrial organisations. Over-production, print costs, national distribution of an expensive and "perishable" commodity to an unorganized market led to the failure of these organizations. Several motion picture companies continue to devote some effort to casual selling of these films: the Pathé Exchange, Inc. has established a large educational department and has maintained a steady output.

While producing and distributing groups were making efforts to open up new channels of distribution of educational films outside the theatre, organized social groups in increasing numbers were seeking ways and means of using motion pictures in their own work. Progressive schools used motion pictures that were available for auditoriums and class-rooms. Religious, social, industrial and civic groups have selected suitable pictures with the help of such agencies as the National Board of Review, the National Federation of Parents' and Teachers' Associations and certain women's magazines.

Experiments conducted by educators have proved that motion pictures have a place in the school and college curriculum. The Chronicles of America Photoplays, a series of pictures showing important episodes in American history, were produced by the Yale University Press. The divisions of anthropology and geology at Harvard university are co-operating with producers in the filming of a series of pictures on human geography and a series on physical geography. The University Film Foundation, sponsored by the Harvard Corporation, has extensive plans for the production of educational and scientific pictures. The recent development of sound motion pictures may extend the influence of educational films for class-rooms and other mediums.

Commercial producers who are making important educational motion pictures for class-room use are Eastman Teaching Films, Inc., the De Vry Corporation and Pathé Exchange, Inc.

Great Britain.—The development of the educational film field in Great Britain, has been largely the work of a few commercial pioneers. The production of instructional films has necessarily been limited and without definite objective. In order to meet, in some degree, the cost of production, they have had to be edited with a view to making a popular appeal. Such films as "Hine Moa," "Livingstone," "Palaver," though originally produced for entertainment purposes, are now constantly in demand for instructional use owing to their value as illustrations to the teaching of geography and history. Films made by the enterprise of industrial companies or trade organizations for advertisement or propaganda purposes, such as the fine film issued by the London *Daily Telegraph,* illustrating the making of a great newspaper, are now sought as valuable aids to technical training.

There are, however, definitely educational films which are the result of scientific research and enterprise and have been produced in collaboration with experts and educationists to record processes of nature, demonstrate the workings of the human system and present various forms and phases of animal life. These include the films of Professor Chalmers Mitchell, Secretary of the Zoological Society, and F. Martin Duncan, analysing animal movement and recording animal psychology; the intensive film studies of bird and insect life by Cherry Kearton and Captain Knight; studies of marine life produced under the auspices of

TECHNOLOGY OF AMATEUR AND PROFESSIONAL MOTION PICTURES

1. Amateur motion picture camera adapted to take a 16mm. film, producing a picture about one-sixth the commercial size
2. A battery of cameras in the studio
3. Motor-driven amateur motion picture projector for the 16mm. film
4. Wooden developing rack on which the film is wound for submersion in a tank containing the developer
5. The sample copy drum room in the laboratory of the Paramount West Coast studio. It is in this room that all of the day's film is dried for immediate projection for the director and the players
6. An example of motion picture film showing pictures with corresponding sound record along the edge. The track is about 1/10 of an inch wide and sound is recorded on it photographically by two methods, the results of which are illustrated in detail in figure 8
7. Negative cutting. When the picture is finished to the satisfaction of the producers, a "master print" is sent to the laboratory for negative cutting. From the cut negatives hundreds of prints are made to be sent out to the theatres
8. Photographic sound records. a, b, c, d: variable density type, representing pure sine waves having frequencies of 100, 200, 400 and 700 respectively. e, f: variable width type, representing pure sine waves with frequencies of 100 and 400 respectively

the Marine Biological Association of Plymouth, etc. In medical science there are important films such as the X-ray photography of F. Melville, which records the pulsations of the heart, and the films of Dr. Canti, showing the development of the living tissues.

Many universities and colleges are at present supplied with projection apparatus but the use of them is very restricted. The elementary and secondary schools have shown a definite interest in the development of the cinema as a medium for classroom teaching. A stimulus to this interest was given in 1928 by the action of the London County Council in sanctioning officially the installation of projection apparatus in classrooms.

In 1928, the Oxford Education Committee undertook some interesting experiments for testing the value of the cinema as an instrument of teaching. Their report emphasized that, for senior work, there were relatively few films in existence designed primarily for teaching. Children's cinema shows are now emerging into the realm of practical business propositions and the demand for films is increasing. The Federation of British Industries has recently made the first attempt to compile a list of the educational film material available. This list, of 300 to 400 films, covers subjects which include Natural History, Botany, Human and Natural Geography, Zoology, Mechanics, Health, etc.

France.—In France the State has promoted visual education. In 1923, the Ministry of Agriculture drew up a scheme for developing the instructional cinema, a grant was made and a permanent cinema commission established. The Agricultural Film library now contains 2,450 films, including instruction on health, social hygiene, child welfare, first aid and kindred matters.

In 1915 an education commission recommended the desirability of introducing the cinematograph into every type of school, of instructing teachers in training colleges in its use, and of setting up an educational censorship. The Musée Pédagogique in Paris administers a State Library of 2,500 educational films and has established a wide system of loan distribution to schools; in 1926 34,000 feet of film were supplied.

Germany.—The majority of the educational films from Germany have been produced by the UFA Company and contain some of the most beautiful material yet available. Science and art here make a wonderful combination. The principal organization dealing with the educational cinema is the Film Department of the Central Institute in Berlin. Local Teachers Associations are formed to act as distributing agencies for the district schools. The German Film Alliance issues a list of German educational material, embracing such subjects as History, Mathematics, Political Economy, School Methods, Athletics, etc.

Italy.—In Italy the production and distribution of films of educational value is encouraged by the State.

Under the auspices of Mussolini an organization has been formed called L.U.C.E. (*L'Unione Cinematographica Educativa*), to produce films recording current events and dealing with educational subjects. All cinema houses must incorporate a certain percentage of "Instructional" films in their programmes.

Russia.—It would appear that the Soviet Government has ambitious programmes in hand and certain scientific films dealing mainly with vivisection exhibited at the European Educational Conference at the Hague (1928), showed a high degree of excellence in production. Considerable use is being made of the cinema in all branches of education, even in the teaching of the alphabet, as in a film showing the letters coming to life and running around the streets of Moscow. In 1927, the educational authorities ordered 2,000 new portable projectors from Germany for demonstration in schools and colleges.

Scandinavia.—The Scandinavian countries are all active in promoting interest in the Educational Cinema. In Sweden, a central body (the *Svenska Kinematografiska Sailskapet*) deals with all such matters, and schools are being induced to instal projectors.

Belgium.—The Educational Film Society of Belgium distributes regularly to its 26,000 members, a fine collection of pictures for weekly exhibition in its many centres.

Holland.—A Municipal Cinema has been established at The Hague, to which teachers may bring their classes to see instructional films. (M. Loc.)

MOTION PICTURE TECHNOLOGY

Motion picture work is technically a branch of photography. The general principles which cover the production of photographic images therefore apply to it, and the article on PHOTOGRAPHY should be consulted. The manufacture of the film is dealt with under PHOTOGRAPHY.

The Film.—The film is supplied in rolls 35 mm. (1·38 in.) wide and 200–1,000 ft. long in the case of the negative films, which are used in cameras. The positive film, on which the prints are made, is supplied in rolls 1,000 ft. in length in order to diminish the necessity for making joins. Negative film is generally supplied in two speeds, known as *Par-speed* and *Super-speed*, while a variety, sensitized by means of dyes, is known as *Panchromatic* film. On the edge of the film are perforations by means of which it is moved through the apparatus, and the exact dimensions of the film and of the perforations are very carefully standardized. Fig. 1 shows the standards adopted by the American Society of Motion Picture Engineers.

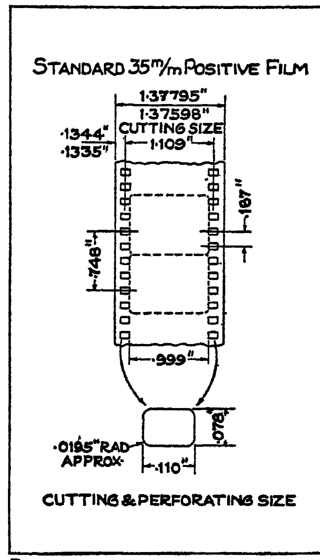

FIG. 1.—DIAGRAM SHOWING DIMENSIONS OF STANDARD 35 MM. FILM

The Camera.—The motion picture camera (*see* fig. 2) is arranged to move the film step by step through the *gate*, in which it is exposed to the light coming through the lens, the intermittent movement being accomplished usually by means of a claw, which

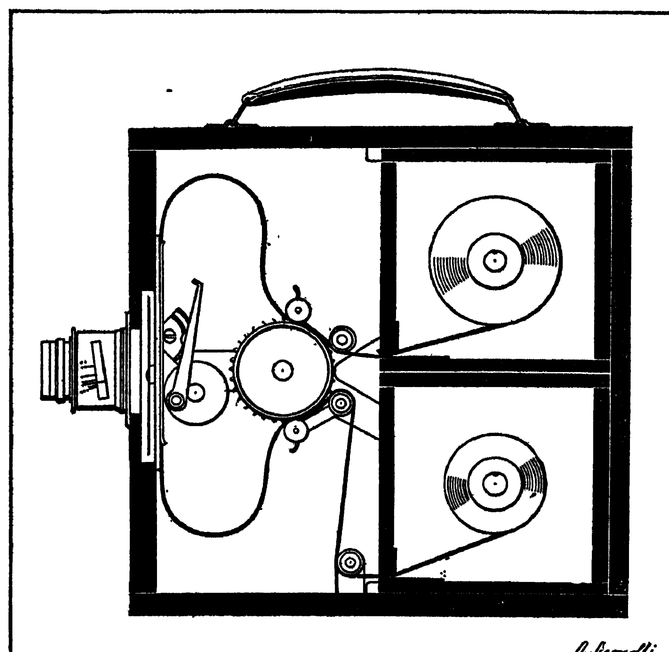

FIG. 2.—DIAGRAM OF MOTION PICTURE CAMERA AND LUMIÈRE CAM

is operated by a cam. The commonest form uses a triangular cam known as the *Lumière* cam because of its introduction by A. and L. Lumière of Lyons, France. By means of a sprocket, the film is fed continuously from the magazine, in which it is held, to the claw, and after passage through the gate is wound on to another magazine by the same or a second sprocket. Between the lens and the gate there is fitted a rotating shutter which protects the film from the light while it is being pulled down by the claw and then exposes it while it is stationary.

The cameras actually used in the motion picture studios are

beautiful pieces of engineering work, costing several thousands of dollars, and are distinctly heavy and complicated. They are supplied with several finders, by which the scene can be viewed or focused on the film. The lenses are carried in a rotating turret or in changeable mounts, so that lenses of different focal lengths can be used on the same scene without the camera being moved, and they are fitted with auxiliary apparatus by which "dissolves" and "fades" can be made and by which portions of the scene can be masked out. An important attachment to these cameras when used for field work is that by which high speed motion pictures can be made, these being taken usually at eight times standard speed. When such pictures are projected on the screen, everything appears to move at one-eighth the standard speed. This is used both for the analysis of motion and also to produce interesting or absurd effects.

For news and "topical" photography, portable cameras are generally employed, a number of these being driven by spring mechanism, so that they can be used in the hand without any tripod. Such a camera makes possible effects which would be very difficult to obtain in a hand-driven camera. Thus, it can be placed in front of an on-rushing train and a photograph obtained without any difficulty or danger, where an ordinary camera would require the excavation of a pit and a considerable amount of risk for the operator.

The studio cameras have magazines taking 200 or 400 ft. of film, a few of them, however, being now made with special magazines to take 1,000 ft. When making a sound film 1,000 ft. reels are used and the cameras are enclosed in special sound proof booths fitted with thick windows of optical glass.

Lenses.—The lenses used on motion picture cameras are almost invariably of large aperture, f/3·5 being about the minimum for the standard lenses, while frequently greater apertures are used up to a maximum of f/1·5. The standard focal lengths are 2 in. (50 mm.) and 3 in. (75 mm.), although for special work lenses of longer focal length are often used, 4 in. and 6 in. lenses being common. For photography of wild animals, etc., very long focus lenses are often used, it being possible by the use of a very steady tripod and an auxiliary support for the lens to use as great a focal length as 17 in. All these lenses are of the anastigmat type, every type of photographic objective, including tele-objectives, being used in motion picture work. (*See* PHOTOGRAPHY APPARATUS.)

The exposure is controlled both by the adjustment of the opening of the shutter and of the aperture of the lens. The standard taking speed is 16 pictures a second, so that if the shutter is set at 180°, the exposure of each frame is $\frac{1}{32}$ of a second.

Studio Lighting.—A few years ago studios were illuminated chiefly by mercury vapour tubes, but now the great preponderance of illumination is obtained by the use of powerful arc lamps known as "Kleigs," "sun arcs," and "broadsides." The current consumption for a small set, involving one room, will be commonly of the order of 300–1,000 kw. "Spot Lights" are used very largely to accentuate highlights, these varying from large projection "sun arcs," so called, to "baby spots" used for small areas. With the introduction of panchromatic film, the use of tungsten lamps is growing rapidly. These are used both in banks for general lighting and also in specially designed reflectors and projection systems for spots.

The great advantage of the tungsten lamp is its lightness and convenience, the chief cost of the lighting in a set being the large staff of electricians required to handle the lamps and point them in any direction required. The light and simple tungsten lamp equipments require a much smaller staff. For use in sound recording the silent tungsten lamps are very advantageous.

Development and Printing. *Development.*—After exposure, the negative film is developed, each scene usually being treated separately so that the best possible results can be obtained. It is customary to cut a short length from the end of the scene, which is purposely made too long, and to develop this by trial. The film is then wound on a rack and developed for the time which has been found best. In this way exposures corresponding to different contrasts in the subject may be developed to give uniform negatives. The racks on which the film is developed are of the type shown in Pl. XIII., fig. 4. Development is done in deep tanks, the film being moved carefully in order to reduce possible marks to a minimum and prevent air bubbles remaining on the film.

The use of machine development for negatives is now commencing, several of the large laboratories experimenting with a view to the development of all their negatives on the machine. This makes the individual treatment of scenes very difficult, but it has the advantage of insuring uniformity and of the avoidance of marks caused by the flowing of the developer around the end of the rack.

The developers may have as their base pyrogallol, metol and hydroquinone or glycin. A developer which diminishes the graininess of the picture uses metol-hydroquinone and contains a very large amount of sulphite, the alkali being borax. Typical formulae are as follows:

	Metric	Avoirdupois
Metol	2·0 grams	13 oz.
Sodium sulphite (desiccated)	18·8 "	7¾ lb.
Hydroquinone	0·5 gram	3¼ oz.
Sodium carbonate (desiccated)	12·5 grams	4¼ lb.
Potassium bromide	0·75 gram	5 oz.
Water to make	1 liter	50 gallons

Average time of development: 6–12 minutes at 65° F (18° C).

	Metric	Avoirdupois
Sodium sulphite (desiccated)	3·0 grams	20 oz.
Glycin	3·0 "	20 "
Sodium carbonate (desiccated)	6·0 "	2½ lb.
Water to make	1 liter	50 gallons

Average time of development: 15–25 minutes at 65° F (18° C).

	Metric	Avoirdupois
Metol	2 grams	13 oz.
Sodium sulphite (desiccated)	100 "	41 lb.
Hydroquinone	5 "	2 lb.
Borax	2 "	13 oz.
Water to make	1 liter	50 gallons

Average time of development: 12–25 minutes at 65° F (18° C).

The fixing, washing, and drying of the negatives are carried on with the greatest care since they are extremely valuable owing to the cost of the production and must be preserved for many years.

For many purposes duplicates are now made from negatives. These are made by printing upon a special duplicating film prepared by impregnating a fine-grained positive film with yellow dye. In this way, low contrast, great latitude, and high resolving power can be obtained. The prints are then barely distinguishable from those made from the original negative.

Printing.—After development a first print is made from the negative. These first prints, known as *rushes,* are viewed as soon as possible so that any scenes that have to be remade can be retaken at once. The negatives are then assembled and a first print is made which is passed over to the producing company to be *cut* and assembled in a form corresponding to the finished picture.

The printing of the negative is performed on a printer which may take one of two forms; in one, the two films are moved intermittently through a gate just as in the camera, the positive film being printed through the negative by means of a light which is cut off by a shutter while the films are being moved. In the other form of printer, the negative and print are moved continuously past a narrow opening and are printed in contact while moving. In both forms it is necessary that the intensity of the printing light should be modified from scene to scene according to the density of the negative. To effect this, a chart is made showing the exposures which it is necessary to give to each scene, and the negative is so notched that as the notches come into place in the gate they will operate a contact mechanism which, acting through a solenoid system, will change the intensity of the printing lamp. Sometimes these changes are produced by the operator.

Positive Development.—The positive film can be developed in the same way as the negative, being wound on racks for this purpose, but in modern practice it is more usual to develop it on an

automatic machine, of which there are several types. In one the film passes through a number of tubes in which it travels from the top to the bottom and then up again, tubes being assigned in succession to the operations of developing, fixing, rinsing, and washing, after which the film passes through a drying cabinet, from which it emerges ready for projection. In another form of continuous machine, tanks are used in place of the tubes, the film travelling in a spiral through the tanks. These continuous machines have a great capacity, it being quite usual for a machine to process as much as 20,000 ft. a day.

Much of the film used is made with a tinted base, the colour being applied to the base during its manufacture. This use of tinted base has supplanted the dyeing of the finished print, partly because it was difficult to apply the dye evenly and partly because the dye used made the gelatine brittle. Not infrequently also the image is toned by various processes, so that by a combination of tinting and toning, pleasing results can be obtained upon the screen. A small proportion of film is coloured either by hand or by the use of stenciling machines, while a growing amount is produced by the processes of natural colour photography (*q.v.*).

Motion Picture Colour Photography.—All the processes of colour photography used for motion picture work are derived from those developed originally for use in still photography. Reference should therefore be made to the section on colour photography included in the article on PHOTOGRAPHY.

The earliest process of motion picture photography was an *additive* process brought out under the name of "Kinemacolor" and developed by G. A. Smith and Charles Urban in 1906. In this process colour sensitive negative film was exposed alternately through red and green filters which so rotated in the camera that one picture was taken through the red filter and the next through the green, twenty-eight individual pictures per second usually being taken. After development, the negative was printed in the usual way, and the positive was projected through a machine fitted with a similar rotating colour shutter. The eye integrated the alternating red and green colours by persistence of vision, and a picture in natural colours was projected on the screen in which, however, the blues were lacking owing to the use of two colours only. The objections to the process were the use of special projecting machines; the loss of light in projection owing to absorption by the filters; the alternation of the colours which produced a flickering effect unpleasant to the eye; and a striping of red and green in the case of rapidly moving objects owing to the red and green objects being taken when in different positions. For brevity, this may be referred to as the "striping defect."

It will be convenient to consider here the problems involved in the design of cameras for taking motion pictures in colour. Such cameras can be of three general types:

1. The pictures can be taken in succession, as in the Kinemacolor process. This involves the "striping" defect.

2. The pictures through the filters may be taken simultaneously by the use of several lenses. Since these lenses must be in slightly different positions, each lens will see the object from a slightly different point of view, and if the scene taken has considerable depth, it will be impossible to register near and far objects simultaneously. This may be referred to as the *parallax* difficulty.

3. The several pictures may be taken simultaneously through one lens, the beam of light being subdivided by systems of prisms. This obviates both the striping defect and the parallax difficulty, but it involves a loss of light which owing to the absorption of the filters is always a great difficulty in colour work. In practice, it is advisable to use all three types of cameras. The first is convenient when photographing still objects, titles, etc. The second is the best for use in the photography of objects moving rapidly, and where there are no objects nearer than 15 ft., the parallax difficulty is entirely negligible. Where close-ups are required and rapid movement is involved, the third type of camera is absolutely necessary, and the difficulty with the exposure must be met by the provision of sufficient light intensity.

In addition to the Kinemacolor process, the "additive" process of colour motion picture photography was used by Gaumont, who employed three lenses, making each picture three-quarters of the standard height. The pictures were taken simultaneously in a three-lens camera and projected simultaneously by means of a triple lens projector. The results were excellent, but great difficulty was experienced in keeping register on the screen, variations in the film shrinkage producing differences in register which had to be corrected while the picture was being projected.

All the natural colour pictures which are available at the present time are made by the "subtractive" processes of colour photography. Essentially, these are two-colour processes in which the two pictures are printed on opposite sides of a film provided with emulsion on each face. A double negative is made in one of the types of cameras described above, and from this all the red filter negatives are printed on one side of the emulsion and all the green filter negatives on the opposite face in exact register with the first set. The two images are then converted into dye images by one of the processes described under colour processes in the article on PHOTOGRAPHY.

The only process which has had much commercial success is the "Technicolor" process. In this process the two negatives were originally printed on separate strips of film with thin base, great care being taken mechanically to preserve exact register at each step of the process. The prints of the two film negatives were converted into reliefs by tanning and washing off and they were then dyed. The two films were then cemented together back to back in exact register to make a film of standard thickness carrying a coloured image on each side. In a later modification of this process, reliefs are prepared by the method described, on thick base, but after dyeing, the dyed images are transferred in register to a clear gelatine coating on ordinary film base, the dye transferring to the gelatine by imbibition. The resulting prints are in character identical with the ordinary black and white film and are therefore more convenient for projection than the cemented double film.

None of the screen plate processes have up to the present been applied to motion picture photography, but the Berthon process (*see* PHOTOGRAPHY) was designed primarily for motion picture photography and has recently been brought on the commercial market as a process for amateur cinematography under the name of Kodacolor. In this process 50 ft. rolls of 16 mm. width film, coated with a panchromatic emulsion and embossed on the back with cylindrical lenses, are supplied in daylight loading spools to fit the 16 mm. amateur standard cameras. The lens, which must be of high aperture, f/2 or over, is provided with a special diaphragm containing a compound filter which takes the place of the ordinary hood. The only changes necessary to make colour photography possible, therefore, are the addition of the special filter to the lens and the use of the embossed panchromatic film. After exposure, the film is processed by a reversal process, by which it is converted into a positive ready for projection. The projector is fitted with a lens having a filter corresponding to the camera filter and on projection natural colour pictures are obtained on the screen, the only limitation being that the loss of light caused by the absorption of the filters involves the use of a screen approximately one-sixth of the area that would be used for black and white.

Projection.—The projection room is a very important part of the motion picture theater. The projectors are installed in a special room fitted with ports through which the light beams are thrown and with arrangements for protection against fire. It is usual to have several projection machines, so that a long picture can be projected without interruption, a new machine being started as each reel runs out.

The projection machines are essentially of the same type as the camera; that is, they involve an intermittent movement of the film during which the light is cut off by a shutter, but this intermittent movement is usually accomplished by means of what is known as the Maltese cross or Geneva movement (*see* fig. 3). This moves intermittently when the operating wheel carrying the pin which enters the cross is moved continuously, and the movement has the advantage over the claw and cam system that it is very robust and can be made to work immersed in oil.

The shutter has usually two blades, one of which is used to cut off the light during the movement of the film, the other inter-

rupting the light, while the film is still, thus diminishing the flicker seen on the screen. This flicker, however, together with the demands of the program, has induced the practice of projecting at a much higher speed than that at which the film was taken in spite of the unnatural effect produced in movements shown on the screen. The standard taking speed is 16 pictures a second or 60 ft. a minute. A typical minimum projecting speed is 85 ft. a minute, while speeds as high as 100 or more are common. It is this which produces the curious action particularly noticeable in people walking.

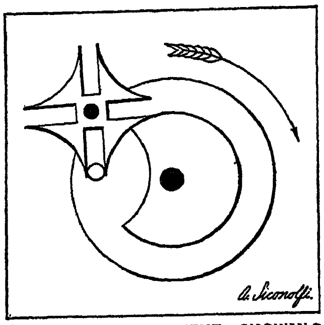

FIG. 3.—ENLARGEMENT SHOWING MALTESE CROSS MOVEMENT

The light sources used for projection are chiefly arc lamps. In modern theatres either high intensity arcs having carbons loaded with chemicals are used or mirror arcs in which the crater of the arc is turned away from the gate and the light from it is thrown forward by a large concave reflector. For projection at a short distance or with small screens good results are obtained by the use of high intensity incandescent lamps.

A great deal of work has been done on continuous projectors in which the film moves through the gate continuously and the image is kept stationary upon the screen by means of some optical system of rectification, such as a rotating ring of lenses which compensate for the movement of the film or rotating prisms or mirrors which hold the image still. These machines have not come into general use though some of them appear to be satisfactory mechanically.

After projection the film must be rewound and should be examined carefully and all damaged or weak places repaired.

Amateur Cinematography.—Cameras have been placed on the market by means of which amateurs can take motion pictures without the use of the elaborate and expensive apparatus employed by the professional cinematographer. Some of these cameras, while of small size, use motion picture film of standard width (35 mm.) and differ from professional apparatus only in the short length of the film which they take and in their low cost. Cheaper forms of projectors taking standard film are also supplied for the use of amateurs, but the cost of the films and of their development and printing has prevented any rapid extension of the use of this apparatus among the general public.

Cameras have been made taking sub-standard film particularly intended for use in amateur cinematography. Two sizes have been introduced: In France, a film 9½ mm. wide has been introduced by the Pathé Co. Nine metres are supplied in magazines for use in a small camera, and the film after exposure is developed by means of a reversal process which transforms the original negative into a positive which is then ready for use in a projector.

The Eastman Kodak Co. in 1923 introduced a film 16 mm. wide to make a picture approximately one-sixth of the area of standard pictures, and they and other manufacturers have placed on the market cameras and projectors adapted to take this small size of film. The film is packed with paper leaders attached to the end on a special reel so that it can be placed in the camera without the use of a darkroom, and after exposure the processing is done by means of a reversal process which transforms the negative into a positive ready for projection. The reversal process gives to the original prints very great freedom from grain, so that when projected they are entirely satisfactory upon the screen. Duplicates can be made from the original positives, standard size film can be reduced to the 16 mm. size, and the 16 mm. film can be enlarged to give pictures of standard size, although in doing this a certain amount of graininess in the resulting print is inevitable.

The cameras supplied for this purpose are portable and are driven by a spring motor (*see* fig. 1, Plate XIII). The projectors also are motor driven and convenient in use (fig. 3, Plate XIII.) so that amateur cinematography is increasing very greatly in its use and applications. In addition to its employment for personal pictures and for the recording of travel, it is much used for scientific and medical work, special apparatus being available for motion picture photomicrography and for high speed photography. Copies of theatrical films are available from libraries and are also sold in large numbers. The small and portable 16 mm. projectors are finding a considerable application in industry and in schools.

Synchronization with Sound.—During the past decade much work has been done on the synchronization of sound with motion pictures. In fact the development of the motion picture itself by Thomas A. Edison was due largely to his desire to have pictures to accompany his newly invented phonograph. The practical realization of the synchronized sound and picture records has been made possible, however, only by the recent rapid progress in electrical methods for the reproduction and amplification of sound.

Thus far, two general methods for obtaining the desired results have been developed. One of these embodies the synchronization of the motion picture with the sound record recorded on a composition disk. This was demonstrated successfully first in 1926 under the name of "Vitaphone." A flat composition disk carrying the sound record is attached to a motion picture projector in such a way that the sound is synchronized with the projected picture. The vibrations imparted to a needle operating in the grooves of the sound disk cause variations in an electrical circuit; they are then amplified by means of a suitable assembly of three-electrode valve-tubes, and finally reproduced through an electrical loud speaker.

The other general method involves the recording of the sound along the edge of the motion picture film by photographic means. The picture area is diminished slightly and a narrow strip approximately $\frac{1}{10}$ inch wide is devoted to the production of a sound record. Records made by the photographic method may be divided into two classes: (a) variable density records, and (b) variable width records. In making the sound record the film is drawn at a uniform linear velocity past a very narrow "slit" which may be either an actual physical slit placed very close to the emulsion surface of the film, or an optical image of a physical slit or narrow light source placed at some distance from the film surface. In the case of the variable density method the intensity of the radiation passing through the "slit" is so modulated that the record consists of a series of lines and spaces extending laterally across the sound track. This type of record is illustrated in Plate XIII, fig. 8. The sound is picked up by means of a microphone such as is used in radio broadcasting stations. The electrical currents are then amplified and used to modulate the intensity of the light incident on the slit. The intensity of the light incident on the slit may be modulated by either of two methods: changing the brightness of a lamp of the gas-filled, glow-tube type, or else in changing the width of an aperture having this dimension variable. The records shown at *a, b, c* and *d,* in this figure represent a pure sine wave having a frequency of 100, 200, 400, and 700, respectively.

In case of the variable width type of record the spot of light illuminating the slit is moved back and forth laterally, the movement being controlled by the amplified electrical currents coming from the microphone. This results in a record similar to those shown at *e* and *f* in fig. 8 of the Plate, these representing pure sine waves of frequencies of 100 and 400, respectively.

The manner in which the sound is reproduced in the motion picture projector is illustrated schematically in fig. 4. The filament of the lamp is imaged by the condenser on a narrow slit as indicated. The objective re-images this slit on the sound track carried by the film. Transmitted light then falls upon a photo-electric cell in which it produces a current depending upon the intensity of the light. (*See* PHOTOELECTRICITY.) As the film travels at a uniform linear velocity, the amount of light passing through the film and falling on the photo-electric cell is controlled by the variation in density or by the variation in width of the sound track image. The variable current flowing through the photo-electric cell is then amplified by the usual three-electrode valve-tubes and finally reproduced as sound by means of a loud speaker. In

some cases the objective shown in the figure may be dispensed with and the slit itself placed very close to the film.

In fig. 6 on Pl. XIII. is shown an example of a motion picture positive film with the accompanying photographic record in the sound track at one edge.

Both systems for the reproduction of sound in synchronism with pictures are capable of giving excellent results, especially where

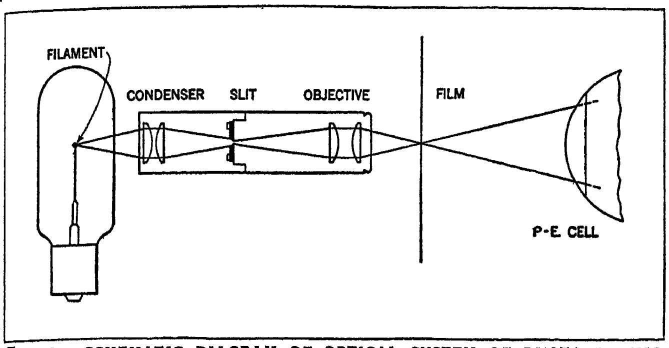

FIG. 4.—SCHEMATIC DIAGRAM OF OPTICAL SYSTEM OF PHOTOGRAPHIC SOUND REPRODUCTION

incidental music suitable for the film is to be supplied, and it is probable that such musical films will to a considerable extent displace the use of orchestras in small theatres. (C. E. K. M.)

MOTION PICTURE THEATRE. The growth of the motion picture theatre is almost as remarkable as the development of the motion picture itself. From the "store-show" with its primitive "movies" of the early days, to the palatial buildings which house the costly film productions of to-day is indeed a far cry. Yet the progress of the motion picture theatre, as an institution of ever expanding influence in community life, is no less remarkable. While its primary purpose is and must always be the entertainment of its patrons, the film theatre has become the gathering ground and often the well-spring of many important public movements and forms of civic expression. In the smaller communities especially, the theatre owner or manager is fast becoming a personage to whom, if any worthy cause calls for public discussion and thought, his fellow citizens look for co-operation and advice. The power of the screen has been said to transcend even that of the newspaper, of which, in its potentialities for public service, it has fittingly been called the complement. Its messages are delivered directly to an audience whose entire thoughts are then occupied by what is registered through the eye. The reaction, therefore, is necessarily immediate and the fullest understanding is obtained. This element of service has been considerably augmented by the introduction of sound pictures, now (1929) in a state of development, but with possibilities of a most pronounced character.

A Civic Centre.—The possibilities of the motion picture theatre as a centre from which the greatest amount of information may be distributed to the largest number of people in the shortest time were not fully recognized until the World War. The work done during and since this period for the Red Cross and kindred institutions is a matter of record. Gatherings of citizens were then furnished ready-made for speakers on behalf of the nations' problems, a service that could not have been secured in any other way with the same facility, and whose value would be hard to measure. But while this emergency may have attracted attention to the growing importance of the screen, during the ensuing years it has established itself as more than a medium for transmitting emergency messages. In its finest aspect the motion picture theatre has become an institution unique in its potential service. It may combine much that formerly lay exclusively in the domain of the church, the school or the newspaper. But in addition to these it has advantages that are distinctively its own in furthering local or national activities. The finest romances of history and fiction have been depicted for the entertainment of the world. Through the news-reels, slow motion pictures, nature studies, travel photoplays and the visualizing of scientific experiments, the people of every nation have been instructed and entertained. The humour of the screen, the comedy relief, so necessary to all well-balanced programs, has improved consistently. Finer wit finds its way to the screen, developing a better sense of humour. Viewing it still more broadly, it may reasonably be hoped that the motion picture theatre will be one of the ultimate factors in developing and establishing the international understanding and good will that all nations hope for but at times seem far from attaining. (R. F. W.)

MOTIVE, in psychology, a general term signifying any element of consciousness which prompts an agent to a decision (from Lat. *movere*, to move). The older psychology usually regarded motives as strictly analogous to mechanical forces exerting pressure or tension, and explained human action as necessarily determined by the resultant of various, possibly conflicting, motives. Contemporary psychological research tends to show with increasing clearness that we must recognize a power of decision in the self, and that the analogy of mechanical forces is inadequate to explain the facts. On this view motives will be regarded as solicitations to act in a certain direction, while the self decides by throwing its volitional weight on the side of the motive which it regards as preferable. The solicitations may come from the most diverse sources: they may be mere desires to avoid some pain or to gratify some appetite; or they may be of higher origin, such as the motive of patriotism, or the desire to advance knowledge. Purposes or ends are often termed motives. "Conflict of motives" means sometimes a conflict of purposes, when the agent has adopted two different lines of action and has difficulty in combining them; or it may mean a conflict of solicitations. It is better to call purposes or ends by those names when they have been definitely adopted by the agent: while they are still under deliberation the term "motive" may be used.

MOTLEY, JOHN LOTHROP (1814–1877), American historian, was born April 15, 1814, at Dorchester (now a part of Boston), Mass., and graduated at Harvard in 1831. He then studied at Göttingen and Berlin, becoming a friend of Bismarck at Göttingen, and after a period of European travel returned in 1834 to America, where he continued his legal studies. In 1837 he married Mary Benjamin, and in 1839 he published anonymously an unsuccessful novel entitled *Morton's Hope*. In 1841 he entered the diplomatic service as secretary of legation in Russia, but resigned his post within three months. Returning to America, he soon entered definitely upon a literary career. Besides contributing various historical and critical essays to the *North American Review*, he published in 1849, again anonymously, a second novel, entitled *Merry Mount, a Romance of the Massachusetts Colony*. About 1846 the project of writing a history of Holland had begun to take shape in his mind, and, after working in the United States, he spent five years at Dresden, Brussels and The Hague in investigation of the archives. *The Rise of the Dutch Republic* (1856) speedily passed through many editions, was translated into French, and also into Dutch, German and Russian. In 1860 Motley published the first two volumes of its continuation, *The United Netherlands*, which was brought down to the truce of 1609 by two additional volumes,

published in 1868. Partly as a result of his letters to the London *Times* on the causes of the Civil War, Motley was appointed U.S. minister to Austria in 1861, a position which he filled with success until his resignation in 1867. Two years later he was sent to represent his country in London, but shortly after was recalled by President Grant. After a visit to Holland he again took up his residence in England, where the *Life and Death of John Barneveld* appeared in two volumes in 1874. Ill-health and the death of his wife now began to interfere with his literary work, and he died at Frampton Court, near Dorchester, Dorsetshire, on May 29, 1877. The merits of Motley as an historian are undeniably great. He has told the story of a stirring period in the history of the world with full attention to the character of the actors and the vivid details of the action, showing as well a most commendable thoroughness in research.

The Netherlands edition of Motley's *Writings* appeared in 1900, and an excellent edition of his historical works was published 1903–04.

BIBLIOGRAPHY.—*See* the *Correspondence of John Lothrop Motley*, edited by G. W. Curtis (1889); O. W. Holmes, *John Lothrop Motley, a Memoir* (1879); M. D. Conway, *Biographical Introduction to The Rise of the Dutch Republic* (1896); *John Lothrop Motley and his Family: Further Letters and Records* (1910), edited by his daughter, Mrs. Susan St. John Mildmay; and the chapters on Prescott and Motley in J. S. Bassett, *The Middle Group of American Historians* (1917), and *The Cambridge History of American Literature* (1918).

MOTLEY, *i.e.*, of many colours, a term particularly used of the parti-coloured dress of the professional "fool" (*q.v.*) of the middle and later ages. The origin of the word is probably to be found in "mote" (O.E. *mot*), a particle of dust, hence a spot or patch.

MOTMOT, the Mexican name of a bird of the genus *Momotus*. The motmots form the family *Momotidae*, very nearly related to the *Todidae* (*see* TODY) of coraciiform birds, the nearest allies being rollers (*q.v.*) and kingfishers (*q.v.*). In outward appearance the motmots have an undoubted resemblance to bee-eaters, but, though beautiful birds, various shades of blue and green predominating in their plumage, they do not exhibit such decided and brilliant colours. The motmots are neotropical, extending from southern Mexico to Paraguay, with the majority of species in Central America. Their ordinary food is small reptiles and fruits, and insects caught on the wing. In adult birds the shaft of the median pair of tail rectrices is devoid of barbs for the space of about an inch a little above the extremity, so as to produce a spatulate appearance. This peculiarity is produced by the motmot itself nibbling off the barbs. Darwin was aware of this strange habit, and suggested that it was an illustration of sexual selection, the bird seeking to make itself more attractive.

MOTOR, ELECTRIC. A machine for converting energy in the form of an electric current into mechanical work. This is accomplished through the use of two fundamental physical phenomena, the first, that an electric current passed through a wire surrounding an iron core causes a magnetic field to be set up in that core and, the second, that an electric current flowing through a wire situated in a magnetic field exerts a mechanical force on the wire tending to force it out of the magnetic field. Fundamentally, then, it may be said that an electric motor consists of four main elements, viz., (*a*) a mechanical structure which supports and protects the magnetic, electric and insulating members, and which transmits the mechanical force to the work; (*b*) a magnetic structure which carries the necessary magnetic flux or field; (*c*) one set of copper coils or windings for carrying the electric magnetizing current which sets up the magnetic field; (*d*) a second set of coils for carrying the electric working current which reacts on the magnetic field to produce torque.

GENERAL CLASSIFICATION

Electric motors are first classified with reference to the characteristics of the supply circuit from which electric energy is to be taken. There are two common forms in which electric energy is commercially distributed. These are *direct current* and *alternating current*. In the first of these forms the current is considered as flowing continuously in one direction around the circuit. The distribution of the current requires only two conductors. Ordinarily these two conductors are two copper wires, but in the case of street railway work a copper wire is used for one conductor and the earth or ground is used as the return side of the circuit. This arrangement avoids the necessity of carrying two trolley poles on the car. In the second form, or *alternating current*, the current is assumed as reversing its direction several times a second throughout the circuit and flowing alternately one way and the other. In the two most widely used systems of alternating current in use in the United States, the current reverses its direction or alternates 50 times per second and 120 times per second. Since two alternations are required to complete a cycle forward and back to the starting point, these two systems are known as 25 cycle systems and 60 cycle systems. This characteristic of alternating current energy is called *frequency*. Electric motors are, therefore, broadly classified as: (*a*) direct current motors and (*b*) alternating current motors. Direct current motors are further classified as: (1) shunt motors; (2) series motors; (3) compound motors; (4) compensated motors. Alternating current motors are classified as: (1) synchronous motors; (2) induction motors; (3) commutator motors. Induction motors are further classified as: (1) squirrel cage rotor motors; (2) phase wound rotor motors.

Structural Description.—In structural detail an electric motor consists of a stationary member and a rotating member, usually called respectively the field or stator and the armature or rotor, as shown in Plate, fig. 7. The stator is composed of (*a*) a *frame*, usually cylindrical, which serves as a mechanical support for the stationary magnetic structure and for the stator windings as shown in Plate, fig. 3. In machines of small and medium capacity, the frame also serves to support the brackets which carry the bearings in which turns the shaft or axle carrying the rotor parts. In direct current motors the frame forms part of the magnetic circuit; it may also support the brushes or carbon blocks which make contact with the rotating commutator and serve as means for introducing line current into the rotating coils on the armature as seen in Plate, fig. 6; (*b*) the stator magnetic structure consisting of individual or salient steel poles bolted to the frame in direct current motors and of a core built up in the axial direction of many thin sheet steel laminations in alternating current motors. These laminations have punched, in their inner periphery, bore slots or notches in which are placed the stator coils or field windings, as illustrated in Plate, fig. 7; (*c*) the field coils or stator windings which are electrically connected to the supply circuit and which conduct into the motor the electric current for magnetizing purposes. In alternating current motors the torque or working current is also taken into the stator windings, but in direct current motors the working current is taken into the armature or rotor through the stationary brushes and the rotating commutator. The rotating member, called the *armature* or *rotor*, shown in Plate, fig. 5, consists of (*a*) an axle or shaft which turns in the bearings and which serves to transmit the mechanical torque from the rotating magnetic core and windings to the pulley or gear or coupling, which is connected to the driven machine or work which is to be done. Mounted on the shaft and inside the bearings is (*b*) the rotating magnetic structure. In direct current motors and induction motors this consists of built-up thin sheets of steel laminations. These laminations have punched in their outer periphery slots in which are located the rotor coils. These laminations may be mounted directly on the shaft or carried through an intermediate member, usually of cast iron, called a spider. In the case of synchronous motors the rotor magnetic circuit consists of an annular steel rim to which are bolted salient radially projecting poles of solid or laminated steel seen in Plate, fig. 1; (*c*) the rotor windings of various forms situated in slots in direct current armatures and induction motor rotors as illustrated in Plate, fig. 5, fig. 2, fig. 4, and surrounding the complete pole in the case of synchronous motors; (*d*) the *commutator* in the case of direct current motors and alternating current commutator motors or *slip rings* in the case of phase wound rotor induction motors and synchronous motors. The function of the commutator and slip rings is described later.

Mechanical Modifications.—The construction just described applies to what are generally known as standard, open, horizontal

VARIOUS TYPES OF ELECTRIC MOTORS

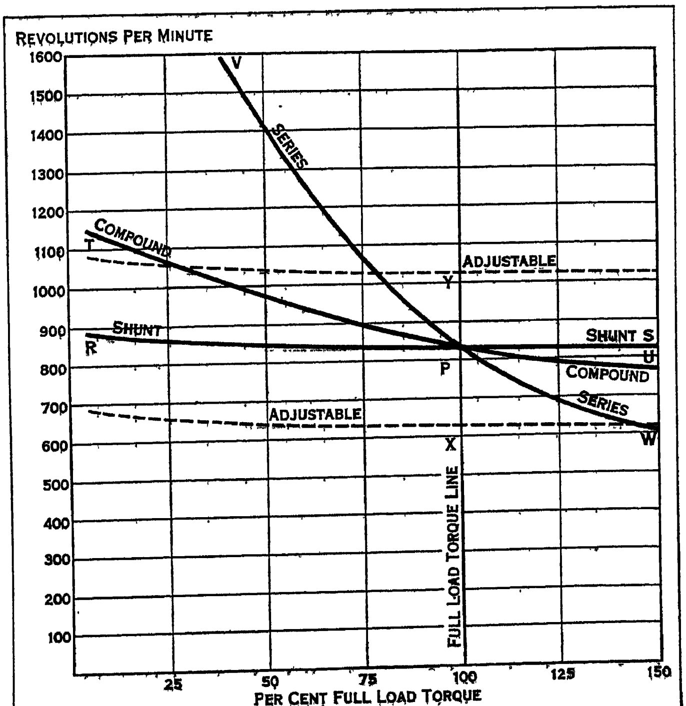
1. Rotating field of synchronous motor
2. Rotor of induction motor of the squirrel cage type. Straight bars of winding, and short circuiting rings form the squirrel cage
3. Completely wound stator of induction motor
4. Phase wound rotor for induction motor with collector rings on the left
5. Rotating member or armature for direct current motor. Commutator shown on the right
6. Direct current motor, industrial type, with open horizontal commutator and brushes seen through bracket opening
7. Cutaway view of wound rotor motor of induction type, showing all parts

motors. In order to take care of special conditions surrounding the work, it is sometimes necessary to make mechanical modifications, such as arranging motors with the shaft in a vertical plane instead of horizontal, or arranging for back gearing as a part of the motor, to secure comparatively low driving speeds. As a protection against mechanical dust or moisture or acid fumes, the openings in the frame and brackets are sometimes closed with covers. Such an impediment to the ventilation results in some reduction in the amount of power the motor can deliver without overheating, but this handicap is offset by the longer life of the winding and insulation and other parts susceptible to breakage or corrosion. In very special cases, as sometimes occurs in traction work, such combinations as the *twin* motor are worked out, in which two separate motors are mechanically connected through gears to one driving axle. Functionally, an electric motor, which converts electric energy into mechanical power, may be looked upon as the direct antithesis of an electric generator (*q.v.*) which develops electric energy by the application of mechanical power to a suitable structure. From this point of view, direct current machines and alternating current synchronous machines may be used reversibly as motors or generators, but alternating current induction motors, as described later, may not be reversed and used as alternating current generators, unless at the same time there are electrically connected in parallel with them suitable alternating current synchronous motors or generators.

Fundamental Mechanical Relations.—The electric motor, after converting electric energy into mechanical force, develops power by means of rotary motion. A consideration of this action involves the *torque* or turning effort and the revolutions per minute at which the torque is delivered. From fundamental physical relations, work is measured by the product of a force and the distance through which it acts, or W=Fs. Work is therefore expressed in foot pounds and may be considered as the work done in raising a weight against gravity. Mechanical energy is also measured in the same units. Further, power is the time rate of doing work and is expressed by dividing Work by Time, or $P=\frac{W}{t}$. The power of electric motors is usually expressed by a unit called a horsepower. This unit is the power required to lift a weight of 33,000 lb. through 1 ft. in 1 min., and the horsepower of a motor is calculated from the torque or turning effort at 1 ft. radius and the revolutions per minute by the formula:

$$\text{Horsepower} = \frac{\text{Torque}\times\text{revolutions per minute}\times 2\times 3{\cdot}14}{33{,}000}.$$

In this formula the torque is expressed as the pull exerted at the end of a lever arm or crank 1 ft. long, and the factors 2 and 3·14 are introduced in order to calculate the number of linear feet that this pull travels in one revolution. Multiplying by the r.p.m. and dividing by the equivalent of one horsepower gives the horsepower which the motor will develop. The simplest conception of torque is that the electric current creates two magnets, one in the stator and one in the rotor. In the case of direct current the stator magnet stands still and attracts to itself the rotor magnet, whose poles are not directly in line with it. At the first glance it would appear that the rotation produced by this attraction would be limited and that as soon as the south poles of the rotor were opposite the north poles of the stator rotation would cease. This would be the case if it were not for the action of the commutator and brushes, which introduce current successively into different coils on the rotor in such a way that as rapidly as a magnetic pole on the rotor is attracted to the nearest stator pole, the current is shifted into the next coil behind, with the result that the poles on the rotor are continually approaching the poles on the stator but never reaching them, since they are continually shifted back automatically by the action of the commutator. Structurally, the commutator consists of wedge-shaped copper bars built up to form a complete circular arch, as illustrated in Plate, fig. 5. These copper segments are separated and electrically insulated from one another by thin strips of mica, which permits attaching the ends of each rotor coil to separate commutator bars. The stationary carbon blocks or brushes make contact with the outer surface of the commutator bars, which, during the rotation, slide under them, and in this manner the current is always led into the proper coils to provide a continuous mechanical pull on the rotor, and this is the torque. As the mechanical work or load which the motor is called upon to do is increased or decreased within the normal rated torque of the motor, the torque developed and the speed at which the motor runs automatically adjust themselves until a stable running condition is reached. This variation in speed with changes in load is known as speed regulation. In the alternating current induction motor, the device of commutator and brushes is not used, but in their place advantage is taken of a principle discovered independently by Nikola Tesla and Galileo Ferraris in 1886. By this principle, if the windings of the stator of such a motor are supplied with polyphase alternating currents, a magnetic field of alternate north and south poles is set up in the stator iron core and this rotates in space independently of the mechanical rotor. This rotating magnetic field sets up or induces in the windings on the rotor electric currents, which in turn create magnetic poles in the rotor and, as a result, the rotor magnetic field is pulled around by the rotating stator field at a slightly lower speed than the rotation of the stator magnetic field. The r.p.m. of the stator field is obtained from the expression $\frac{\text{cycles}\times 120}{\text{number of poles}}$; *e.g.*, on a 4 pole, 60 cycle motor the r.p.m. of the rotating magnetic field would be $\frac{60\times 120}{4}=1{,}800$ r.p.m. The no load r.p.m. of the physical rotor is very close to this so-called synchronous speed, but the full load r.p.m. of the physical rotor drops a few per cent below this. In the alternating current synchronous motor, Plate, fig. 1, which is built like an a.c.



BY COURTESY OF THE WESTINGHOUSE ELECTRIC COMPANY

FIG. 1.—CURVES SHOWING THE VARIATION OF SPEED WITH LOAD OF VARIOUS TYPES OF DIRECT CURRENT MOTORS

generator, the magnetic field of the rotor is separately set up by direct current from an independent source. In this case the rotating magnetic field of the stator which is set up by polyphase alternating currents locks in magnetically with the rotor field and pulls it along synchronously. For this reason the no load and the full load speed of a synchronous motor are given by the expression: revolutions per minute $=\frac{\text{cycles}\times 120}{\text{number of poles}}$. The electric and magnetic relations in both direct current and alternating current motors and their theory and method of calculation are

quite analogous to the same conditions in *electric generators* (*q.v.*).

Counter Electro Motive Force.—This is one fundamental principle to which special reference is here made as it is most useful in understanding the action of motors. Counter electro motive force is a back voltage generated by any motor all the time that it is operating as a motor and is of such a direction and such a value that it is directly opposed to and nearly equal to the voltage which is applied to the motor from the supply circuit. The slight margin between the applied line voltage and the generated back voltage (perhaps of the order of 3% to 5% of the line voltage) is just sufficient to send through the resistance of the windings a current which is automatically exactly sufficient to produce the torque required to drive the mechanical load. If the load increases the motor slows down a trifle and generates a little less back voltage, so that the difference between the line voltage and the back voltage is a little greater and hence an increased current flows in the motor, producing an increased torque to balance and carry the increased load. If the load decreases, the motor speeds up and less torque results.

SPEED-TORQUE CURVES AND CLASSIFICATION

In the application of electric motors to their work the characteristic to which the greatest attention must be paid is that of the variation of speed under load. A graph is drawn from standstill to the maximum speed which the motor attains, showing how the torque increases or decreases as the speed rises or falls. Such a graph or characteristic curve is called a *speed-torque* curve and illustrations are shown in figs. 1, 2, 3, 4. With reference to their speed-torque curves, motors are classified as follows: (*a*) constant speed; (*b*) varying speed; (*c*) adjustable speed; (*d*) multi-speed.

Constant speed motors run as nearly as possible to a fixed speed, regardless of change of load from no load to the maximum load which can be carried. A varying speed motor is one whose speed changes widely with load changes, in general running slowly under heavy loads and fast under light loads. Adjustable speed motors have the added possibility that by changing a rheostat or equivalent resistance control device the no load speed of a motor may be changed over a considerable range, but when once set for a given speed it will run practically at that same speed at any and all loads. Multi-speed motor is a term usually applied to alternating current motors, the connections to whose windings may be changed in such a manner as to change the number of magnetic poles and hence the speed of the motor. Like the adjustable speed motor, these motors, when connected for one speed, run practically constant at that speed, even under load changes.

Speed-torque Classification of Direct Current Motors.—The classification of direct current motors into shunt, series, compound and compensated has reference to the manner in which the magnetizing coils on the field magnets are wound. This is shown schematically in fig. 5. In the shunt motor the field coils consist of a relatively large number of turns of wire of relatively small cross section connected directly across the full line voltage as in *A*, fig. 5. It will be seen in this diagram that the field winding and the armature winding are in parallel across the supply voltage, or, using another expression, the field is *shunted* across the armature. In the series motor, whose connection is shown in *B*, fig. 5, the field coils are made up of a relatively small number of turns of relatively large cross section and the field coil is in series with the armature winding instead of being in parallel with it as in *A*. In the series motor the same current flows through the field coils that flows through the armature winding, and hence it is doubly effective, once in magnetizing the field and once in producing torque in the armature. For this reason the torque in a series motor is proportional to the square or second power of the current up to the point where the magnetic material of the motor is saturated with magnetic flux so that the field strength cannot be further proportionally increased. In the compound motor, whose connections are shown in *C*, fig. 5, the field poles are provided with a shunt coil and also with a series coil so that the motor partakes partly of the characteristics of a shunt motor and partly of a series motor. The compensated motor illustrated in *D*, fig. 5, is a special form of compound motor to which there is added a compensating

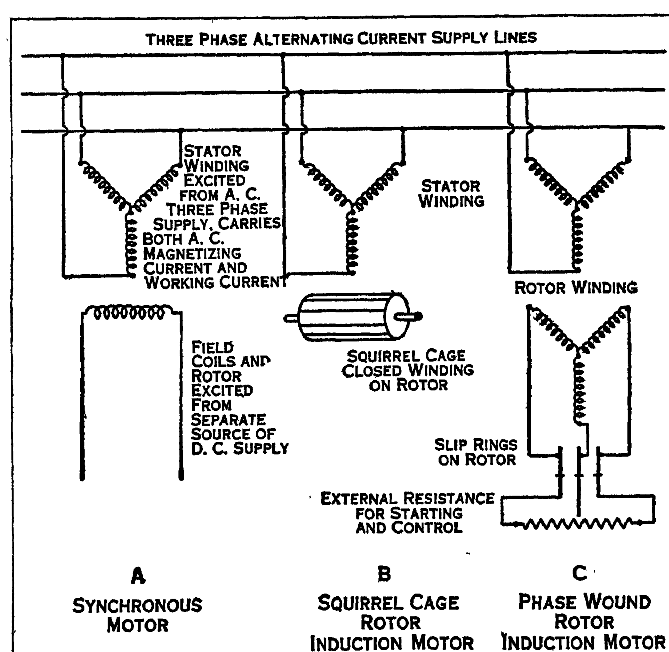
winding in series with the armature winding which compensates for the magnetic effect on the field of the working currents flowing in the armature. This compensating winding is placed in slots in the faces of the poles. The compensating winding decreases the sparking which occurs to some extent on the commutator of all commutating motors, and also makes possible a very flat speed torque curve with almost no change in speed from no load to maximum overloads. The curves in fig. 1, illustrate the behaviour of the different classes of direct current motors when the load on the motor is varied. The load on the motor in per cent of full load torque is plotted horizontally and the revolutions per minute vertically. The same rated torque and the same full load r.p.m. has been chosen for three motors wound and connected respectively according to the schematic diagrams *A*, *B* and *C*, fig. 5. This full load point is shown as *P* in fig. 1 and the r.p.m. is 840. In the case of the shunt motor, the speed is seen to be fairly steady, varying from 880 r.p.m. at no load, point *R*, to 835 r.p.m. at 150% load, point *S*. The shunt motor is therefore classified as a constant speed motor. In the case of a compound wound motor, the speed regulation is much wider and the speed changes from 1,150 r.p.m. at no load, point *T*, to 770 r.p.m. at 150% load, point *V*. For this reason the compound motor is classed as a varying speed motor. In the case of the series motor, fig. 1, the change in speed with change in load is still greater, ranging from 1,600 r.p.m. at low load, point *V*, to 620 r.p.m. at 150% load, point *W*. If the load were removed entirely the speed would rise still higher than 1,600 and the motor possibly damage itself. It is therefore necessary on a series motor to make sure that some restraining load is provided at all times.

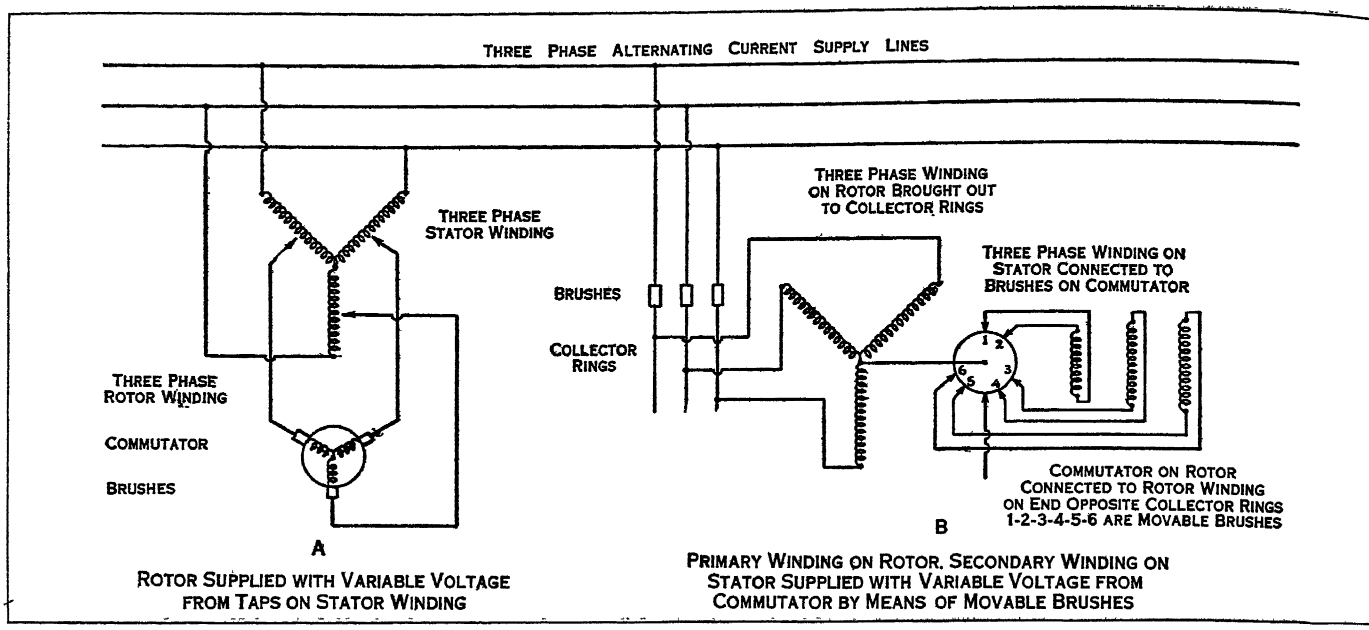
The case of the direct current adjustable-speed motor is illustrated by the dotted curves of fig. 1. This is shown to be a shunt motor provided with a rheostat in the shunt field, which permits the full load speed to be adjusted between a range of 640 r.p.m. and 1,040 r.p.m. When adjusted for one full load speed, the change in speed with changes in load is small, and is comparable, as shown by the two dotted curves, with the curve of the straight shunt motor. The speed-torque curve of a compound compensated motor can be varied in accordance with the desired application, but in general the motor is classified as a constant speed motor. The speed-torque curve would be similar to that of the shunt motor shown in fig. 1. Consideration of the curves in fig. 1 leads to the conclusion that where constant speed is required at all loads, a shunt or compound compensated motor would be used. As a matter of practice, nearly all modern shunt motors have a light series field coil to prevent the speed actually rising at heavy loads due to the demagnetizing effect of the armature current on the magnetic fields. Where heavy loads must be started and moved slowly and where lighter loads must be moved at higher speeds, a series motor is used or a very heavily compounded motor. Compound motors are used in general industrial work to drive tools such as punch presses and shears which are equipped with heavy flywheels. They are advantageous here for two reasons; first, because the starting duty is heavy, due to the



BY COURTESY OF THE WESTINGHOUSE ELECTRIC COMPANY

FIG. 6.—SCHEMATIC CONNECTION DIAGRAM FOR ALTERNATING CURRENT MOTORS OF THE SYNCHRONOUS AND INDUCTION TYPES

weight and inertia and, second, because their dropping speed curve as load comes on allows energy to be drawn from the flywheel to meet the sudden severe peak. After the peak load passes, the motor accelerates again and restores to the flywheel the borrowed energy. In the case of all direct current motors there is a direct relation between the speed and the supply voltage applied to the armature, as was inferred in the definition of counter electro-motive force. Advantage has sometimes been taken of this to secure varying or adjustable speed characteristics, either by placing an external resistance in series with the armature



BY COURTESY OF THE WESTINGHOUSE ELECTRIC COMPANY

FIG. 7.—SCHEMATIC CONNECTION DIAGRAMS FOR COMMUTATOR A.C. MOTORS

or by changing the supply voltage applied. The resistance method is objectionable because it wastes some power, but the variable voltage scheme is efficient and finds an important application in the control of large high-speed passenger elevators. As an additional desirable characteristic a direct current motor may be so controlled that it will act as a generator while the load is being brought to rest, and thus considerably lessens the duty and the wear on the mechanical brakes. This is particularly useful in the case of series and compound motors, as in the case of railway motors. This feature is called *dynamic braking*.

Table I. gives some typical applications for the different classes of direct-current motors.

motors on the main roll drives of steel mills and similar applications, a system has been worked out by using auxiliary machines of the commutator type which gives a true adjustable speed characteristic for the whole combination. This arrangement involves too much complication and expense to justify it in case of comparatively small units. Aside from this rather special application, the broad legitimate field of alternating current motors is in constant speed and varying speed applications. So great is the mechanical simplicity and ease of installation and maintenance of the squirrel-cage rotor induction motor that it is doing a major percentage of the world's work in general industrial applications where constant speed is required, coupled with comparatively infrequent starting duty.

TABLE I.—*Typical Application of Direct Current Motors*

Type of motor and control	Control speed	Adjustable speed	Varying speed

Compound compensated motor	Continuous strap steel rolling Paper machine drives		Large reversing steel mill drives Mine hoists
Series motor			Railway work Crane work Industrial hoists

Speed Classification of Alternating Current Motors.—Many attempts have been made to develop an adjustable speed alternating current motor which would compare favourably with its direct current competitor, but up to the present time this cannot be said to have been accomplished. If it were readily feasible to vary the frequency of the alternating current supply this could be accomplished, but since such variation is attended with too much complication this field is practically monopolized by the direct current motor. In the case of very large induction

The typical constant speed alternating current motor is the *synchronous motor*, a diagram of which is shown in fig. 6, which, as has been explained, has an unvarying speed at all loads so long as the frequency of the alternating current supply remains constant. The synchronous motor in structural detail originally exactly duplicated an alternating current generator but as so designed had very little starting torque and could not be applied where compelled to start under load. Later an additional wind-

ing similar to that of a squirrel cage rotor induction motor was added to the rotor, and at the present time synchronous motors have sufficiently good starting characteristics to permit their use on many industrial applications formerly covered by induction motors. The speed-torque curve of a synchronous motor is a straight line at synchronous r.p.m. If loaded beyond the capacity of its torque to hold it in step the motor stops entirely and comes to rest. The synchronous motor has a very desirable characteristic from the standpoint of the supply system, in that it can be made to draw from the line a magnetizing current for its stator winding, which is said to be leading the supply voltage in time phase and which, therefore, compensates for the magnetizing current of induction motors on the same system, which current is said to be lagging. Expressed in a practical way, if a supply system is entirely loaded up with induction motors so that its generators cannot take on any more load, it may be possible to install additional synchronous motors and develop additional mechanical power without adding to the electrical load on the generator. So valuable is this characteristic that at times synchronous motors are run on a system without any mechanical load, merely to furnish this the so-called *leading current*. When so used, a synchronous motor is called a *synchronous condenser*.

The ***induction motor*** may be either a constant-speed or a varying speed motor as may be seen in fig. 6. In the squirrel cage rotor type, a constant speed motor has a comparatively low electrical resistance in the copper bars and short-circuiting rings of the rotor winding as shown in Neg. 105,482. If a varying speed characteristic is desired, the electrical resistance of the rotor winding is increased. The speed-torque curve for a constant speed squirrel cage rotor induction motor is shown in fig. 2. It will be noticed that the torque at start is about $1\frac{1}{2}$ times normal full load running torque and that as the motor speeds up the torque increases until maximum torque is reached and then decreases until the motor runs steadily at a torque corresponding to the load. Unlike the synchronous motor, which runs at all times at synchronous speed, or $\frac{\text{cycles} \times 120}{\text{number of magnetic poles}}$, it will be noted that the induction motor falls away slightly from synchronous speed and, at full load, runs, for example, at 3% to 5% below synchronous speed. This departure from synchronous speed is characteristic of the induction motor and is called *slip*. In the case of the varying speed squirrel cage rotor induction motor with high electrical resistance in its rotor winding the *slip* will be much greater, at rated full load torque and the speed torque curve will be typified by that of fig. 3. In this case it will be noted that maximum torque occurs at start and that the torque decreases as the speed increases. Also, that the *slip* at full load is 25% or much greater than in the case of the constant speed motor. Such a speed-torque curve is desirable where heavy loads are to be started, perhaps frequently. Moreover, the varying speed motor has the further desirable characteristic that the current required in starting is less. On the other hand, it is less efficient when running continuously by a percentage represented by the increased slip. The phase wound rotor induction motor has a coil

winding on the rotor of relatively low electrical resistance, and the terminals of the windings are brought out to collector rings on the shaft as shown in Plate I., fig. 7. Contact is made with these rings by means of carbon blocks or brushes, so that it is possible to insert or cut out resistance external to the motor and in series with the windings. In this manner a very flexible control is secured, since a number of different speed-torque curves can be obtained for the same motor, depending on the amount of this external resistance. This is shown by fig. 4 in which the speed torque curve 7 would be that with all resistance cut out of the circuit, and curves 1 to 6 inclusive those with varying amounts of external resistance. From this it might appear possible to get adjustable speed characteristics, but this is not the case for the reason that a change in load represented by X^1 on curve 7 produces a slight change in speed represented by Y^1 but the same change in load on X on curve 1 produces a considerable change in speed shown by Y. From this it appears that on curve 7 the motor could be rated as *constant speed* but on all other curves it would be *varying speed* and the motor is so applied. In connection with all induction motors, the torque developed varies as the square of the line voltage applied.

Alternating Current Commutator Motor.—The number of commutator motors used on alternating current is much smaller than other types as the problem of commutation is more difficult than with direct current. However, the demand for an alternating current motor which would be suitable for railway work resulted in various forms of single phase motors (requiring a single supply wire and trolley) having a speed-torque characteristic equivalent to that of a series direct current motor. The schematic diagrams for such motors are shown in fig. 6, *A, B* and *C*. These are known as series, repulsion and doubly-fed motors. A demand for a polyphase alternating current motor with adjustable speed characteristics resulted in several so-called "alternating current shunt motors." The schematic diagrams for two of these are shown in fig. 7, *A* and *B*. In *A* the brushes on the rotor are fed with current from taps taken off of the stator winding and hence at varying voltage. In *B* the rotor winding has collector rings at one end of the rotor and a commutator at the other. The supply line connection is made to the collector rings instead of to the stator winding. On the commutator are two sets of movable brushes. Opposite ends of the three separate phase windings on the stator are connected to corresponding pairs of brushes. Due to the shifting of the brushes, a changing voltage is impressed on the stator winding and speed adjustment results. These types of motors are expensive and complicated and are little used. Three general applications have been made of single-phase alternating current commutator-type motors. The first, as a means of getting better starting characteristics on a single phase industrial motor. Unlike a polyphase induction motor, a motor which is supplied from a single-phase supply line has no starting torque unless auxiliary windings or so-called phase splitting devices are used. However, a single-phase commutator motor of either the repulsion or series type has very good starting characteristics. Therefore it is the practice of several manufacturers to build a single-phase induction motor which has a rotor similar to the armature of a direct current motor. In addition, the rotor has a device actuated by centrifugal force which short circuits all the commutator bars after the rotor is up to speed and it then continues to run as an induction motor. This motor is referred to as *repulsion-start, induction-run motor*. The second application of alternating current commutator motors is in connection with heavy traction or the electrification of steam railroads. Here the motor has been used both as motive power for electric locomotives and in so-called motor cars. The third general application for alternating current commutator motors is as auxiliaries to large wound rotor induction motors where adjustable speed must be had and where the application of direct current is not feasible. This system has been applied to main roll drives in steel mills and to variable ratio frequency changers, where two alternating current supply systems are to be tied together for the exchange of power, but where there must be some flexibility allowed to each system in the maintenance of its exact frequency. Some typical applications of alternating current motors are shown in Table II. In comparing the uses of direct current motors with those of alternating current, it may be said that alternating current is more widely used but that certain classes of work can be handled more satisfactorily by direct current motors. Broadly, these are: industrial cranes, high-speed passenger elevators, adjustable speed machine tools, heavy steel mill reversing rolls and city street railway service. Aside from these applications, alternating current motors are preferred because the general distribution of energy by any other means than alternating current is practically prohibitive on account of cost.

MOTOR-BOAT, a small vessel propelled by a motor, especially by a petrol (gasolene) engine. Its history dates from 1885 when, it is believed, a launch was successfully propelled by an internal-combustion engine by J. J. R. Hulme of London. In 1886, in Germany, Daimler fitted a boat with one of his engines of 1 h.p. and carried 11 persons in it on a lake in Württemberg. Within a few years the Daimler Co. was turning out numerous motor-launches at Coventry. Relatively slow progress was made and the public generally did not, seemingly, become convinced of the reliability of motor craft. Hence the reliability trials which were organized by the Royal Automobile Club in 1904, and the cross-Channel race for motor-boats in the same summer, both of which were afforded much publicity, helped considerably to bring before the general public the possibilities of motor-boating as an enjoyable and safe pastime. It may be recorded as indicating the reliability of marine motors at that date that in the trials in question a 20 hours' test was included and 15 out of the 16 boats which were entered satisfactorily completed this arduous trial. Since 1904 steady progress has been made in the development of motor-boating, also in the design of motor-boats and engines suitable for their propulsion. With the increasing congestion, due to the very large number of cars on the roads in the thickly populated countries, it is evident that more and more people are taking to motor-boating, and there are definite indications that the pastime will become increasingly popular, particularly in view of the recent production of cheaper boats, of which details are to be given later. With these, the cost of motor-boating has been reduced to a figure less than that of motoring.

Construction of Motor Boats.—For the construction of pleasure motor-boats, wood is utilized almost exclusively, except for large yachts. Steel is heavier and more expensive than wood, but it is occasionally employed for certain special types of boat, also not infrequently in the tropics. Duralumin, an alloy of aluminium, has been adopted in Germany for cruisers and launches, where extreme lightness was required but it is unlikely to find any general application. A large number of different woods are used in the construction of boats. Mahogany, oak, pitch-pine and teak are commonly employed for planking, teak being specially good for boats built for service in the tropics, but it is expensive. The keel is usually of oak, pitch-pine, oregon pine, larch or American elm, and the stem and stern-post of English oak or larch. British oak is one of the best materials for boatbuilding, but for the planking or skin of a boat Honduras mahogany represents, perhaps, the finest timber. Pitch-pine is cheaper and has advantages for

TYPES OF AMERICAN MOTOR-BOATS

1. "Miss America II.," which made 80.567 statute miles an hour in 1921. This record stood until "Miss America VII." made 92.838 in 1928
2. "Greenwich Folly," winner of the "Gold Cup" in 1926 and 1927. She is a 25 ft. displacement boat with a motor of 625 cu. in. cylinder capacity
3. Outboard racers at the start of a contest. The two boats in the foreground have streamlined decks
4. A "Gold Cup" racer just as she started to capsize
5. A high speed racer. These boats when driven fast in a choppy sea will often leap entirely clear of the water
6. The winner of the New York-Albany Race of 1928, a 12 ft. boat driven better than 25 knots by an outboard motor
7. A 41 ft. cruiser which has been successful in a number of long distance races for her type
8. Hundreds of these 34-footers have been built by one large manufacturer of standardized boats

boats intended for arduous service. Wood boats are either clench or carvel built. In the former system, the bottom of each plank distinctly overlaps the plank below, whilst in carvel construction, the adjoining planks are planed on their edges and butt together. The carvel method is by far the more common, as it has a better appearance and offers less resistance to the water. Most boats have single planking but two skins are not uncommonly employed, with canvas between. The inner and outer planks are usually arranged diagonally, or there is a horizontal outer skin and a diagonal inner planking. The two skins are fastened with nails, but another system is that in which the two skins of planking are sewn together by stitches of linen thread.

Types of Motor Boat.—Motor-boats may be divided roughly into two categories: displacement craft and hydroplanes. In the former, the same amount of water is displaced, no matter at what speed the boat travels. A hydroplane, on the other hand, when running at high speed raises itself partly out of the water, and the amount of water displaced is less than when at rest. The result is that the water resistance is reduced and higher speeds are possible than with displacement boats. The hydroplane principle is, however, seldom used except for racing craft and is, in fact, practically ineffective at speeds under about 15 or 16 knots. The famous coastal motor-boats used so successfully during the World War are examples of high-speed hydroplanes which virtually skim over the water, the bottom of the hull being built with a step, generally disposed near the centre. In some craft two or more steps are provided. The open launch is, perhaps, the most popular type of motor-boat. Referring first to inboard engined craft (outboard motor-boats will be dealt with later), this class is generally constructed in sizes from 16 ft. up to about 35 ft., and is equipped with engines varying from 6 h.p. to 30 h.p. The speed is usually moderate, but fast launches are now gaining favour, more particularly in America. Craft with speeds of 25 to 35 knots are standardized, one firm in the United States turning out more than 1,500 of these annually, whilst standard boats with a guaranteed speed of 55 knots are now produced. The tendency of builders of modern launches, both of the high speed and moderate speed classes, is to design them somewhat on automobile lines so far as the steering wheel, controls and electric starting equipment are concerned. A reason for this policy, apart from its general convenience, is that many of the purchasers are those with motoring experience. The 18 ft. Brooke runabout, which is fitted with a 10 h.p. engine, is a British example of the latest type of launch designed to meet the demands of such buyers.

Cabin Cruisers and Auxiliaries.—The cabin cruiser represents one of the most attractive types of motor craft. It is built in sizes of from 20 ft. in length upwards, with cabin accommodation and is usually constructed as a seaworthy boat capable of making good passages at sea under moderate or even rough conditions. Owing to the fact that a small increase in speed calls for greatly augmented engine power, and consequently, higher fuel consumption and capital cost, the average speed of cabin cruisers is from 8 to 10 knots. Thus, a vessel of from 25 ft. to 30 ft. in length usually has an engine of from 10 h.p. to 20 h.p. In England the average price of a 30 ft., 8 to 10 knot cruiser is about £500 to £750 according to equipment. In the United States, however, where petrol is relatively cheap, the large majority of cabin cruisers are constructed with much higher speeds than those in the United Kingdom, and express cruisers, vessels from 25 ft. to 50 ft. in length, having speeds of 20 to 25 knots, are very popular. As with all other classes of motor boats in the United States, cabin cruisers are, for the most part, built in quantities as standard productions. In England and, in fact, most other parts of the world, there is a larger proportion of boats built to individual requirements, but the tendency towards standardization becomes more marked every year.

The "auxiliary" is a type of motor-boat which appeals to the sailing man and is gradually replacing the pure sailing yacht. It is designed essentially for sailing but in it is installed an auxiliary motor; this is usually only of sufficient power to propel the yacht at a speed of about 6 knots. In small auxiliaries specially designed motors are provided, occupying very little space and scarcely detracting from the sailing qualities of the boat. The drive is taken through a clutch so that the propeller may revolve freely when the yacht is under way or, in some cases, a feathering propeller is used, the blades of which can be fixed in a vertical position when the yacht is under sail. Specially designed boats are built for use with outboard motors, that is to say, engines which, complete with propeller and propeller drive, together with the fuel tank, can be attached to the stern of the boat. These craft are constructed, either as hydroplanes or displacement boats, from 8 ft. to 16 ft. in length, and as speeds of over 30 m.p.h. can be attained with such craft equipped with outboard motors rated at 8 h.p., outboard motor-boat racing has become extremely popular in America, also in Great Britain and to a certain extent on the Continent. Outboard motor-boats have led to a wider field of popularity for motor-boating than was possible with inboard engined craft, since these launches with speeds of between 20 and 30 m.p.h. can be purchased for £100 or less.

Motor Boat Engines.—For the vast majority of motor-boats engines operating on petrol are used, similiar in general design to those fitted to motor-cars. A certain number of motor-boats built for service in Great Britain and in some other parts of the world are fitted with paraffin engines, but these are seldom used in America. For large yachts, engines known as semi-Diesel, Diesel or other types operating on cheap, heavy oil, are employed. The main difference between marine motors and those used for motor-cars is that the speed of the former is generally lower since, especially for moderate speed craft, it is inefficient to drive the propeller at more than 1,000 to 1,200 revolutions per minute. Otherwise, the differences between the marine and car engines are only in detail. The paraffin motor is also similar except that a vaporizer is utilized, this being heated by the exhaust gases so that the fuel may be effectively vaporized before admission to the cylinders of the engine. The compression pressure of the paraffin motor is, however, slightly lower than that of the petrol type and the output for given cylinder dimension is 10% less. The tendency, however, especially in America, is to increase the speed of marine motors, and engines operating at 1,600 to 2,000 r.p.m. are frequently fitted to the faster types of boat. Higher speeds mean smaller, lighter and cheaper engines, and these are the reasons for their adoption, even at the loss of a certain degree of propeller efficiency. In some boats, in order to improve propeller efficiency, fast-running engines are used in conjunction with reducing gears, so that the propeller turns at about one-half the speed of the engine. Petrol and paraffin engines, apart from outboard motors, are almost invariably built as four-cycle motors. The outboard engine, a type which has become extremely popular, consists of a horizontal engine driving a vertical shaft, at the bottom of which the propeller is driven through bevel gearing. It also incorporates the fuel tank and the whole unit can be clamped direct to the stern of the boat. It is started by turning the fly-wheel. The majority of modern outboard engines have two opposed cylinders and are of such weight that they may be conveniently carried by one man. For the most part they are built in three standard sizes, rated at approximately 2½, 4 and 8 h.p. respectively, the prices ranging from £25 to £70. When specially designed for high speed the actual power developed is considerably in excess of the rated output. They are suitable for attachment to dinghies and relatively heavy boats, whilst, as mentioned above, they are often fitted to specially-built racing hulls, thus forming high speed racing craft.

Most motor-boats are driven by means of a propeller coupled through the shaft to the engine. Where the depth of water is restricted, aerial propulsion is sometimes resorted to. This involves the employment of a propeller similar to that used on an aeroplane. It is mounted on a framework and is driven by a petrol engine through a chain or by other means. Hydraulic propulsion is also utilized in some instances with shallow draught boats, the engine in this case driving a pump through which the water is drawn. The propulsive efficiency is less than with a submerged propeller, but with the latest Hotchkiss system the difference is not large. (A. P. C.)

Outboard Motors.—The early small marine motors manu-

factured for installation in rowboats and canoes were miniature editions of larger plants and had all their complications of shafting, stuffing boxes, foundations, etc. For their use, the boat had to be especially built or adapted for them. Shifting a motor from one boat to another was a difficult task. In 1906, Ole Evinrude, of Milwaukee, Wis., began experimenting and in 1910 applied for a patent on a small, light, single-cylinder, internal combustion motor, which could be attached to the stern of a small boat and readily detached when desired.

The new machine rapidly grew in popular favour and others manufactured somewhat similar devices. These were all of the two-cycle type, some with two opposed cylinders. Most of them weighed about 40 lb. or less and developed from 1½ to 2½ horsepower. In 1928 the larger motors developed more than 35 h.p. and weighed nearly 150 pounds.

In 1924, the outboard motor was grudgingly granted a place on the schedules of some of the important regattas. They were used to drive boats of many models and sizes and the fastest speed was less than 9½ knots. In 1925, racing boats were especially designed for outboard motors, more powerful motors appeared, and speeds increased to 14½ knots. Thereafter each season saw power and speed going up, reaching 20·3 in 1926 and 29·1 in 1927.

The year 1928 saw remarkable strides in the popularity of the outboard motor, both in the United States and in Europe and also in Australia. Long distance racing was inaugurated in 1928, the first event being time trials between Albany and New York in which the winner ran the 115 nautical miles at an average speed of 25·4 knots. Other contests followed, some in open water, such as the race from Boston to New York, upwards of 250 m., of which a large proportion was at sea, and another on Lake Michigan, which was run under adverse weather conditions. The 202 m. from Peoria, Ill., to St. Louis, Mo., was covered at better than 33 knots. In shorter races over club courses, 2, 2½ or 3 m. to the lap, remarkable speeds were made that summer, culminating at Peoria, Ill., in September, where two boats did better than 40 m. an hour as the average of six runs each over a measured mile. "Spirit of Peoria" averaged 41·478 and "Cyclone" did 40·453 in these trials. Their motors were four-cylinder machines, the cylinders being in pairs and opposed. In October at the outboard championship race at Wilmington, N.C., records were made over the 4 miles. In class A, "Bumble Bee" did 25 m. per hour; in class B, she did 33·57; in class C, "Rubber Baby II." did 35·55; and in class D, "Orange Blossom" made 37·07.

In the Albany–New York outboard marathon, early in 1929, the winner, "Miss Eastern," averaged 37·4 m. per hour.

Motors are classed for racing by piston displacement, the classes being as follows: class A, under 14 cu.in.; B, 14 to 20; C, 20 to 30; D, 30 to 40; E, 40 to 50, etc., advancing by tens. The 1928 records in statute miles are: class A, 25 m. per hour; class B, 34·346; class C, 39·764; class D, 41·748; class E, 35·022. (C. H. Ha.)

MOTOR CAR, a self-propelled freight or passenger vehicle adapted to run and be steered on ordinary roads. Most motor vehicles are propelled by internal combustion engines, but some are driven by steam and some by electric motors although these are, for the most part, limited to commercial service. This article is divided into two parts: (1) general description of the development of the automobile with particular reference to conditions in the United States; and (2) a description of the motor car with particular reference to Europe.

In general, motor vehicles may be classified into three groups, according to the service they render. First, there are private passenger cars for transporting individuals, usually seven or fewer in number; second, commercial passenger vehicles for transporting a large number of persons; and third, commercial goods vehicles for transporting materials and goods. During the past 25 years in England, continental Europe, Dominion of Canada, and the United States, a wide variety of terms has been used to designate these three classes. The passenger car has been called "motor car," "motor vehicle," "automobile," "autocar," "auto," "car," "motor," etc. In 1928 "automobile" is the universal word in America, while elsewhere the term "car" is common. The commercial passenger vehicle has been known as "omnibus," "charabanc," "motor-bus," "coach," and "bus." While all these terms are used more or less generally, the last, "bus," is used extensively in the United States and Canada and also to no small extent in England and on the Continent. At the present time the "charabanc" is an open vehicle for conveying tourists about, employed in Europe. "Lorry" is now distinctly the English and "truck" distinctly the American name for the commercial goods vehicle. Coaches, omnibuses and buses, and lorries and trucks are treated elsewhere. This article deals only with motor cars, or automobiles.

HISTORY OF THE MOTOR CAR

It is difficult to assign definite dates for events in the progress of the automobile. Many men were working on the same problems in different places. This brief outline can point out only the trends and major developments. The self-propelled vehicle dates back to the middle of the 18th century. Credit for the first "road wagon" propelled by its own engine, is generally given to Nicholas Cugnot, a Frenchman, who about 1770 built a three-wheeled carriage, with a cumbersome steam power plant operating on the single front wheel. It is claimed that this steam carriage could run at the rate of 2½ m. per hour, but it had to stop every hundred feet or so to make steam. Cugnot's second vehicle, produced in 1771, is still preserved in the Conservatoire des Arts et Métiers, Paris. (Some histories of the automobile state that his first car is still preserved and not his second car.) During the latter half of the 18th century a few other attempts were made to build steam carriages, many of which were not capable of operating under their own power. The next century, however, saw a number of steam vehicles put to practical use in transporting passengers. Among these early experimenters were: Oliver Evans in America, making a car in 1787; Trevithick, England (1801); Gordon, England (1824); James, England (1824); Gurney, England (1828); James, America (1829); Summers and Ogle, England (1831); Hancock, England (1824–36); Church, England (1832); Maceroni and Squires, England (1834); Dudgeon, America (1857); and Butler, England (1883). Gurney put three steam coaches into operation on a route near London covering about 3,644 miles. Around the same time Walter Hancock built the first of nine steam carriages that were to operate on a route regularly.

Starting about 1831, the English parliament enacted laws which practically eliminated the steam coaches from the roads. Among these might be mentioned the Red Flag Law, which required that a man precede the horseless carriage, carrying a red flag by day and a red lantern by night. In addition, the toll roads and bridges raised the charges for the steam carriages until they could no longer operate at a profit. As a result, there was little development of the horseless carriages in England until after 1896, then the restrictive law was repealed. In Germany and France interest turned toward the internal combustion engine to replace the cumbersome power plant of these early steam vehicles. In 1885–86 Gottlieb Daimler (Germany), patented his high speed internal combustion engine, which is generally credited with revolutionizing automotive transportation Nevertheless, there is some disagreement among historians on this point. Some state that in 1875 Siegfried Narkus (Austria) built a four-wheeled vehicle powered by an internal combustion engine. Benz (Germany), in 1885, produced a tricycle with an internal combustion engine. Credit is commonly given to Krebs for the first petrol or gasoline automobile incorporating many of the essential features of the modern car. In 1894 he designed the Panhard car with a vertical engine under a bonnet or hood, at the front, and a modern type chassis. The car also had the common type of sliding gear transmission operated by the right hand, clutch and brake pedals, and a foot accelerator.

About 1896 or 1897 considerable work was carried on in Germany, France, England and the United States on the development of vehicles driven by internal combustion engines. These cars varied greatly in detailed design; some had the same general arrangement as the Panhard, while others were patterned on the

familiar horse-drawn carriages which they were expected to supplant. The motor car is not the product of a single inventor nor even of men within a single century. Among the European pioneers there were: Daimler, Benz, Maybach, Krebs, Panhard, Levassor, Royce, Serpollet, De Dion, Bouton, Gibbon and Roots; and among the American pioneers were Duryea, Olds, Haynes, Winton, Ford, King, Maxwell, Apperson, Riker, Clarke, Stanley, White and Franklin. These automobiles were produced, of course, in very small numbers because of the limited manufacturing facilities and of the small consumer demand.

In 1903 the Association of Licensed Automobile Manufacturers was formed in America to grant licences to manufacture motor cars under the Selden patent (U.S. patent No. 549,160, Nov. 5, 1895), and for eight years was a powerful force in the development of the new industry. By limiting licences to concerns which were held to be "good and reliable," the association doubtless protected both the automobile industry and its customers from unscrupulous exploitation, and stabilized somewhat the general conditions of production and market competition. The National Automobile Chamber of Commerce was organized in 1913 to succeed the association (strictly speaking, the National Automobile Chamber of Commerce succeeded the Automobile Board of Trade, which succeeded the Association of Licensed Automobile Manufacturers). Among its activities was the "cross-licence" agreement whereby any member might use the patents held by any other member, without paying a royalty. While never adhered to quite universally, this agreement still (1928) holds for patents issued previous to 1925. At that time the life of the agreement ran out; and it was not renewed mostly on account of the commercial aspect of large private developments.

Until 1909–12 the automotive industry was, in general, chiefly concerned with developing a product that at least would operate. Some cars, of course, were marketed in this period; these in essential details were nearly as satisfactory as cars designed in recent years. During the experimental period, cars of every description were produced with alternatively chain, bevel gear or friction drive; bar, tiller or wheel steering; planetary or sliding gear transmissions; and with the number of cylinders ranging from one to eight, with a few twelves and sixteens. The prejudice against a new and radical invention, poor road conditions, the comparatively high original cost, the cost of maintenance and the general unreliability of the cars, all tended to retard rapid introduction of motor vehicles. The sporting phase of the automobile was recognized long before it was commonly appreciated that the automobile provides a thoroughly reliable, economical, comfortable and rapid means of individual transportation.

After 1909–12 the production of sufficient cars for a growing demand and marketing and distributing facilities became of great importance. Problems of time payments and the extensive purchasing of cars on an instalment payment basis, trade in used cars, dealer organization and advertising have been demanding the attention of manufacturers, in addition to problems of quantity production and engineering. During this period also the internal combustion engine has almost entirely superseded both steam and electric motors for propelling automobiles. The electric vehicle is confined, for the most part, to use for short distances, over improved roads. The expansion and growth of the motor car has, in a large measure, proceeded abreast with the building of good roads, development of alloy steels and improvement of rubber. The need for rapid and reliable individual, or private, transport has existed for a long time; and when the automobile was recognized as fulfilling that need, its adoption was rapid not only in Europe and America, but in late years, all over the world.

(U.S. National Automobile Chamber of Commerce, *Facts and Figures*, 1929 ed.) Figures 1921–28 include Canadian production. In 1927 the Canadian production was 146,870 cars.

The table in the first column shows the yearly production and registration of passenger cars in the United States.

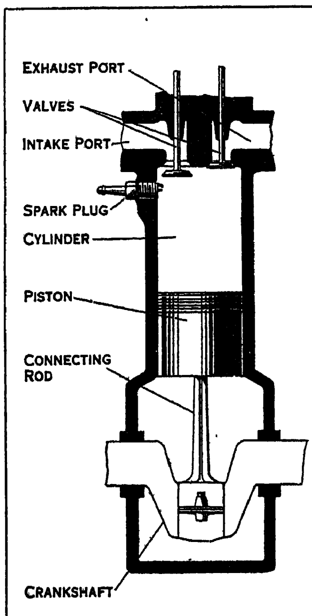
The figures for the United States for 1927 represent 85% of the production and 75% of the registration of the world, for in that year 3,650,000 cars were built in total for all countries and 29,639,000 were in operation. The following table shows the relation of population to motor car registration (based on passenger vehicles) in various countries in 1927:

	Persons per car in 1927
Australia (white population)	19·7
Canada	12·9
France	69·1
Germany	313·0
Great Britain*	63·9
Italy	495·8
New Zealand (white population) . . .	13·3
South Africa (white population) . . .	21·4
United States	7·0

(*Motor Industry of Great Britain*, 1927 ed., published by the Society of Motor Manufacturers and Traders Association.)

THE AUTOMOBILE ENGINE

The automobile engine transforms the chemical energy of a mixture of air and fuel (petrol or gasolene) into mechanical energy which can do work, *i.e.*, move the car. The engine is often also called the power plant. Essentially the engine consists of: (1) an enclosed cylinder in which a gaseous mixture of air and fuel is burned; (2) a piston which moves back and forth in the cylinder; (3) a connecting rod which links the piston to a crankshaft; and (4) a crankshaft which changes the reciprocating motion of the piston into rotary motion. This is shown in fig. 1. Other parts necessary for the operation of the engine are: (1) A carburettor for mixing air and fuel, with an intake pipe to conduct the mixture up to the inlet valve; (2) inlet valve, which, upon being opened, admits the mixture into the cylinder, and upon being closed, prevents this charge from escaping; (3) a spark-plug, which ignites the charge at the proper time; and (4) an exhaust valve, which opens to allow free exit to the charge after it has delivered part of its energy to the engine. Practically all automobile engines operate on what is called the four-stroke cycle. The stroke refers to the travel of the piston in the cylinder, from top to bottom for one stroke, and back again for another stroke. Four strokes complete one cycle.



BY COURTESY OF GENERAL MOTORS CORPORATION

FIG. 1.—DIAGRAM OF SIMPLEX ENGINES

The following events take place in the engine during one cycle:

(1) *Intake stroke:* The inlet valve is open. The piston travels down the cylinder, and, acting like a pump, draws in a charge of

air and fuel through the inlet valve. Strictly speaking, atmospheric pressure forces the mixture of air and fuel into the cylinder to fill up the space left vacant and partially evacuated by the receding piston. (2) *Compression stroke:* The valves are both closed. The cylinder is full of the air-fuel mixture. The piston travels up the cylinder, and compresses this mixture into a very small space at the top of the cylinder. Shortly before the piston reaches the upper end of its travel on the compression stroke, ignition occurs. Due to the fact that an appreciable time is required for the charge to burn, the timing of the spark is required to be somewhat in advance of the top centre position of the piston to produce maximum turning effort on the crankshaft. (3) *Expansion stroke or power stroke:* The valves are still closed. The air-fuel gaseous mixture has been ignited and burned. During the burning high temperatures have been produced. High temperature is accompanied by a substantial increase in pressure, reaching about 400 lb. per square inch. The pressure of the burned gases forces the piston downward. (4) *Exhaust stroke:* The exhaust valve is open. The piston travels upward, and forces the burned gases out through the exhaust valve. This fourth stroke completes the four-stroke cycle, and the next stroke starts a new cycle. This is shown in fig. 2.

FIG. 2.—FOUR-CYCLE ENGINE CUT AWAY

In addition to this four-stroke cycle, there is another plan of engine operation, called the two-stroke cycle. The effective distinction between the two lies in the fact that in the former, one out of *four* is an expansion, or power stroke, whereas in the latter, one out of *two* is a power stroke. At first thought, this distinction seems advantageous for two-stroke cycle engines, but many problems arise in the actual design and construction of such an engine, which, up to 1928, have outweighed automobile advantages. (*See* INTERNAL COMBUSTION ENGINES.) Usually the two-stroke cycle engine has no valves, but has ports in the wall of the cylinder near the bottom. The piston uncovers these ports on the lower portion of its travel. A new charge of gas and fuel, which has been previously compressed in an auxiliary chamber, rushes through one port and forces the spent gases out from the cylinder through the other port. The piston compresses the new charge, ignition and expansion take place, and the piston travels down ready for a new charge. Considerable inventive effort has been applied to gas turbines, rotary engines, and numerous other types of power plant. In actual construction and operation, however, the advantages are more apparent than real, and none has progressed beyond the experimental stage.

Cylinders.—The cylinder, as the name implies, is a cylindrical cavity with one end closed and one end fitted with a movable piston. The closed end, which is called the "combustion chamber," differs in shape in different engines. There is, in fact, a definite relation between the engine performance and the shape of the combustion chamber, which must be determined specially for each engine type. Apart from the combustion chamber, the principal features of cylinders are their number, size and arrangement. One, two and three cylinder engines have dropped largely into disuse in modern automobiles because of the great variation in turning effort due to the comparatively infrequent power strokes. Also, such engines usually require large fly-wheels, a fact which results in heavy, sluggish engines. Even the four-cylinder engine is less in demand than hitherto, because the trend of public desire is ever toward smoother engines. The present six-cylinder engines are considered very smooth, but engines of eight and even more cylinders are in use and can be made still smoother but only at additional cost and complication.

The size of the cylinder is determined by its diameter, or "bore," and by the portion of its length which is swept by the top of the piston, and which is called the "stroke." The "displacement" is an expression of the volume swept by the piston from the top to the bottom of the stroke, and equals $\frac{(\text{Bore})^2 \times \pi \times \text{stroke}}{4}$. The total displacement is the sum of the displacements of all the cylinders. The "compression ratio" is an expression of the relation of the volume of the gas when it is fully expanded to the volume of the gas when it is fully compressed. The compression ratio equals $\frac{V+D}{V}$, where V=volume of the combustion chamber for one cylinder, and D=displacement for the same cylinder.

These dimensions, volumes and ratio are of very considerable importance in engine design, although it is impossible to assign to them any absolute value in terms of resulting performance. The power an engine is capable of producing depends on many factors—combustion chamber design, number of cylinders, displacement and compression ratio, speed of the crankshaft, weight of the reciprocating parts (pistons, connecting rods, etc.), valve size, valve timing and a large number of other factors. Each factor is built into an engine design with all the others in mind to accomplish a definite range of performance and service. The arrangement of the cylinders, at the present time, is limited to three types—"in line," **V**, and horizontal opposed. All fours and sixes have their cylinders "in line," *i.e.*, vertical and one behind another from the front to the back. Eights and twelves may have their cylinders in line or disposed like a **V**. In the latter type the angle between the two banks of cylinders is usually either 90° or 60°.

Piston and Connecting Rod.—The piston transmits the gas pressure to the crankshaft where it is available as torque. The side pressure of the piston against the cylinder is the torque reaction. Technically, the torque and torque reaction are best demonstrated by the analysis shown in fig. 3. Due to the inertia of the reciprocating parts, an inertia torque, and an inertia torque reaction are also set up in the same manner as that of the torque and torque reaction shown in fig. 3. The piston is directly exposed to the heat of combustion and unlike the cylinders cannot be directly water cooled. It must be well lubricated because the side pressure of all the pistons applied to the cylinder walls will produce a rotative effect at least equal to that present at the crankshaft. In a high speed engine or one with very heavy pistons it may be considerably more. The problem in piston design is to use as little metal as possible, and to use that metal to the greatest advantage in conducting the heat to the piston rings and to the

MOTOR CARS IN PROCESS OF PRODUCTION IN ASSEMBLY LINE AND TESTING ROOM

1. View of unified assembly line in a large motor car plant. Overhead are the conveyors, three in number, which deliver the wheels by gravity to the belt conveyors, on their way to the assembly lines below. Each wheel is retarded while passing through the conveyor belt from the gravity overhead conveyors to the assembling racks on the floor

2. View of testing room at the end of the assembly line. Engine hood and front seat of each car are removed for ready inspection. Benches in foreground have spare parts and testing apparatus for use in each stage of the testing process

piston skirt or bearing surface. Then it will pass through the cylinder walls and be carried away by the cooling water. In a well-designed piston, such as that shown in fig. 4, the temperature of the entire piston head will be uniform and well below the point at which roughness would be caused under severe operating conditions.

The connecting rod links the piston to the crankshaft. The upper, or "small," end is connected to the piston by means of a pin, variously called "piston pin," "wrist pin," and "gudgeon pin." The lower, or "big," end is connected to the crankshaft by means of that part of the shaft called the crankpin. Since the connecting rod is a rapidly moving part, it is made as light as is consistent with rigidity and durability. Although some manufacturers use an aluminium alloy, most use steel.

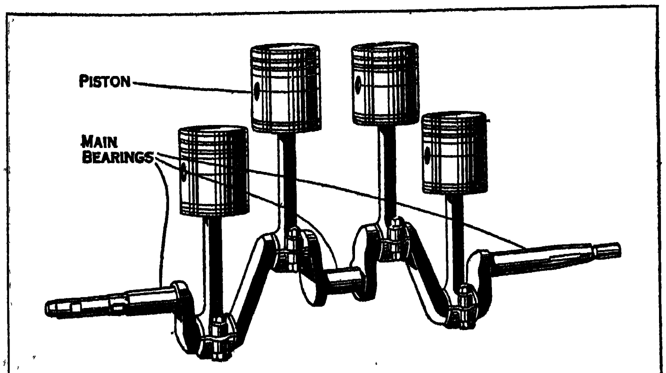
FIG. 4.—PISTONS

Crankshaft.—The crankshaft of an engine is the means for converting the straight line motion of the piston into rotary motion. It is a shaft which runs in bearings at the open or lower ends of the engine cylinders, and has portions of its length bent into **U** shaped cranks. The portions of the shaft which are concentric with its centre line are called journals; the eccentric portions, crankpins. These may be seen clearly in the illustration, fig. 5, which shows a crankshaft for an engine having four cylinders in line. The journal runs in bearings supported in the engine crankcase. The crankshaft is connected to one end of the connecting rod and the piston is connected to the other, and as the piston reciprocates in the cylinder the crankshaft revolves. When the cylinders are arranged in line, there is one crankpin for each cylinder; when they are arranged in a **V**, two cylinders share one crank. In aeronautical, but not automobile, practice, as many as 9 or 11 cylinders may operate on a single crank.

The bearings in which a crankshaft runs are named "main bearings." Practice in respect to the number of cranks for each main bearing varies from the use of four cranks between adjacent



BY COURTESY OF GENERAL MOTORS CORPORATION

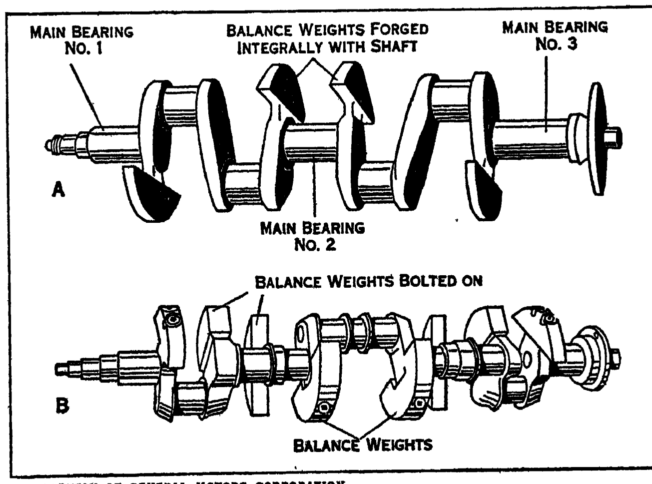
FIG. 5.—PISTON ASSEMBLY

main bearings to the use of alternate cranks and main bearings. Generally, the larger the individual cylinder, the fewer is the number of cranks between adjacent main bearings. Engines with a single crank between journals will have one more main bearing than they have cranks. The following table shows all possible arrangements of cranks and main bearings, the most common being marked by an asterisk.

Number of Main Bearings

Type of engine	4 cranks between main bearings	3 cranks between main bearings	2 cranks between main bearings	1 crank between main bearings
1 cylinder	..	..	..	2
2 cylinder	..	..	2	3
4 cylinder vertical or 8 cylinder **V**	2	..	3*	5
6 cylinder vertical or 12 cylinder **V**	..	3*	4*	7*
8 cylinder vertical	3	..	5*	9*

Balance and Vibration.—Automobile engines of the present day are run at such a high speed that dynamic forces become as great as, if not greater than, the forces due to the gas pressures. Centrifugal force on the cranks of a crankshaft becomes of prime importance, since any small lack of balance causes severe vibration at high speeds. Shafts are approximately balanced statically in all conventional engines by virtue of the cylinder arrangements, since there are cranks equally spaced at all angles; but practically all crankshafts have to be balanced dynamically (a running balance) to correct for unbalanced disposition of the material in the rough forging. Often, in high speed engines, counterweights are attached opposite the cranks, so that



BY COURTESY OF GENERAL MOTORS CORPORATION

FIG. 6.—CRANKSHAFT

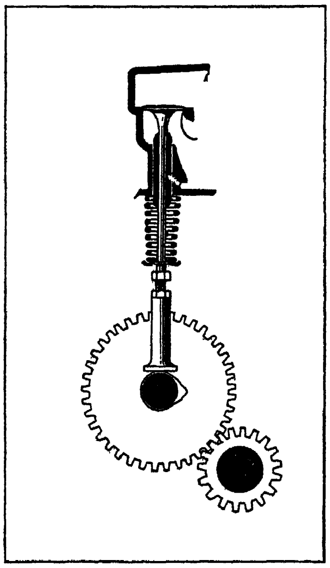
their centrifugal force tends to counteract that of the cranks, which otherwise would cause the engine to vibrate. The use of such weights greatly reduces the load on these bearings and lessens engine vibration. Fig. 6 shows two types of counterbalanced crankshafts.

Another species of vibration, torsional vibration, makes itself felt in long engines, especially if there are six or more cylinders in line, and if the crankshaft is comparatively flexible. The impulses, particularly of the front cylinders, tend to wind up the crankshaft, which, of course, springs back when the force is relieved. Due to its elasticity and inertia, the shaft does not come to rest immediately, but vibrates, winding and unwinding, about the fly-wheel, which, because of its inertia, does not change its speed of rotation to any appreciable extent. When the torsional impulses have the same frequency as the natural period of the crankshaft, or a multiple of this natural period, the vibration becomes very severe, and steps must be taken to reduce or counteract it if smoothness is desired. On some cars this is done by the use of a small fly-wheel attached at the front end of the shaft by a slipping clutch; when the shaft winds up, or vibrates, slippage occurs at the clutch, permitting relative motion between the shaft and fly-wheel. In this way energy supplied to the crankshaft by the vibration-exciting forces is converted into heat. On other cars an inertia weight is mounted on the crankshaft through springs. The inertia weight counteracts the torsional vibration of the shaft by vibrating out of phase with it.

A single cylinder develops power on only one stroke out of four, and in order to function it must be driven for the other three strokes. A heavy wheel, or *fly-wheel,* usually of cast iron, is attached to the crankshaft, and its momentum causes the shaft

to continue revolving through the idle strokes. As the number of cylinders increases, the overlapping of these power strokes makes it possible to decrease materially the size of the fly-wheel. A heavy fly-wheel decreases the accelerating ability of the car, especially in the lower gears, while a very light fly-wheel is likely to transmit the fluctuations in engine speed to the transmission and there set up gear noises. The final size of the fly-wheel is, therefore, a compromise between these two limits.

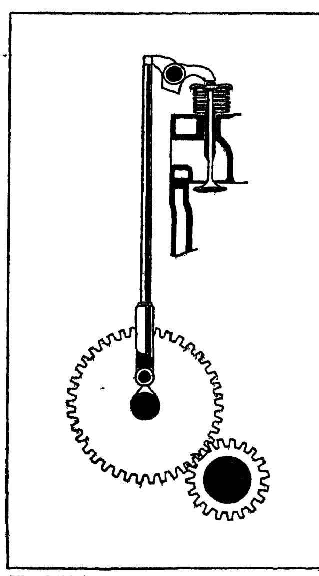
Valve Mechanism.—Engines are described with reference to the arrangement of the valves for admission of the air-fuel charge and for the expulsion of the burned gases. The L head (fig. 7) has the valves extending in an approximately vertical direction downward from the combustion chamber to the valve tappet (an intermediate member which is actuated directly by the valve camshaft). The *valve-in-head* engine (fig. 8) has its valves extending upward from the combustion chamber. This results in a very good combustion chamber form and in simple direct passages for the inlet and exhaust gases. If the camshaft is in the lower position, as in the L head, long push-rods are required to actuate rocker arms which, in turn, operate the valves. Occasionally, the camshaft is located above the engine, and operates directly on a tappet which is attached to the valve stem. This arrangement requires elaborate gearing and introduces lubrication problems. The F head is a combination of the two types mentioned, one valve per cylinder (usually the exhaust valve) being located as in the L head type and the other located as in the valve-in-head type. In the T head, one or two valves are located on each side of the cylinder. In another type, the valves extend horizontally outward from the combustion chamber.



BY COURTESY OF GENERAL MOTORS CORPORATION

FIG. 7.—L HEAD TYPE MECHANISM

Each of these types of valve arrangement has inherent advantages which account for its use in any particular engine. Each has also certain disadvantages. Various factors which must be taken into consideration in valve design are volumetric efficiency, combustion chamber design and resulting smoothness of combustion, weight of reciprocating parts, cost and complexity, lubrication, quietness and adjustment. These types of valve are all classified as "poppet valves"; there is still another type called "sleeve valves."



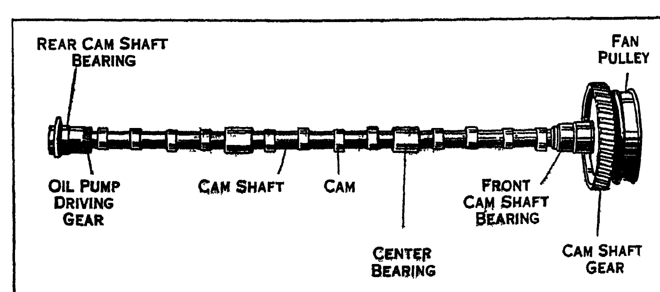
BY COURTESY OF GENERAL MOTORS CORPORATION

FIG. 8.—VALVE-IN-HEAD OPERATING MECHANISM

The "sleeve valve" engine has its cylinder made larger than the piston. Two thin-walled sleeves lie between the cylinder and the piston. The two sleeves are reciprocated through connecting rods by a small eccentric shaft which, like a camshaft, rotates at one-half engine speed. The two sleeves reciprocate in a manner with respect to each other such that two ports, cut in their walls in certain positions, will register together and also with two ports provided in the cylinder wall. The ports are timed to register in such a way that two sets of ports will function as inlet, and two sets as exhaust, valves. Sleeve valve engines have attained fairly wide use in several makes of automobiles, both European and American, and in some makes of commercial vehicles. The single sleeve is another type of sleeve valve engine which, up to the present time, has had limited use. In order to accomplish the proper register of ports, the single sleeve has an oscillating circular motion in addition to the reciprocating vertical motion. Ever since the beginning of the automobile, a great deal of inventive effort has been spent on unconventional types of valve, viz., rotary, piston, disc and others, but these have either been proved impractical or have not shown sufficient gains to justify their use.

Valves.—All poppet valves have the same general form. A circular flange, called the head, is joined to a stem by an easy curve. The valve seat is formed on the outer edge of the head, on the same side as the stem, and is usually bevelled at a 45° or 60° angle to the stem, although in a few cases it is made flat (or at 90° to the stem). The valve is very carefully ground or lapped in its place on the valve seat to ensure against gas leakage from the combustion chamber when the valve is closed. The valve is opened by the camshaft to permit gas flow and is closed by a compression spring which transmits pressure through a spring seat or washer fitted to the end of the valve stem. Both the inlet and exhaust valves are directly exposed to the heat of combustion. The inlet valve is cooled quite well by the incoming mixture during the inlet stroke. The exhaust valve must operate under what probably is the most severe condition that exists in the engine. It can be cooled only by the loss of heat into the cylinder wall through the valve seat, and the valve stem guides. Although exceptionally good heat-resisting alloy steels have been developed for valves, nevertheless, valves must be very carefully designed, for otherwise the most carefully prepared valve seat will not last.

Camshaft and Timing Gears or Chains.—The valve operation is controlled by the camshaft (fig. 9), which is rotated by the crankshaft, either by means of gears or through a chain and sprocket wheels, at one-half the crankshaft speed. A fixed relationship of the camshaft with the crankshaft must be maintained in order that the valves may be opened and closed in a fixed time-relation with the various events in the cylinder. This is done by using datum points. The datum point on the crankshaft is marked on the fly-wheel and registers the uppermost position of some specific piston. The datum for the camshaft is usually marked on the gear or sprocket, and registers with the crankshaft datum point. On nearly all modern engines an individual cam is provided on the camshaft for each valve. Between the valve stem and the cam there is a valve lifter, or tappet, one end of which rides on the cam, and the other end of which abuts on the valve stem. In the overhead valve engine, there are other intermediary parts—a push-rod and a rocker arm.



BY COURTESY OF GENERAL MOTORS CORPORATION

FIG. 9.—CAMSHAFT

The cam is so shaped that at some point located within a very limited range, the valve lifter will push the valve off its seat slowly enough not to cause violent impact between the parts of the valve mechanism. This "opening" point on the cam profile must be located for each cam in a very definite position with respect to the datum point on the camshaft. The remainder of the cam profile is designed to raise the valve to its maximum lift and then permit it to be lowered by the spring so that it will close without violent impact between the valve and the valve seat at a point also closely limited. Only about one-quarter of the

cam profile lifts the valve directly. The rest of it acts as a means of controlling the action of the valve spring. Since this condition exists, cam design and valve spring design are so interrelated that they can be said to constitute a single problem.

Cooling System.—The internal combustion engine is a heat engine in which power is developed by converting the heat energy generated through the combustion of the fuel into mechanical energy. Therefore it would seem wasteful to have a cooling system for dissipating a portion of the heat of combustion; however, in order to control the temperature of the combustion chamber to prevent pre-ignition, warping of the valves, loss of power through lower volumetric efficiency, excessive piston expansion and rapid breakdown of the lubricating oil film, especially on the cylinder walls and pistons, it is necessary to dissipate approximately 33% to 40% of the total heat of combustion of the fuel through the cooling system. In all types of cooling systems the heat is dissipated to the surrounding air by radiation or conduction.

In the water-cooled system which is commonly used for automobile engines the cylinder walls, combustion chamber and valve seats are surrounded by a water jacket generally cast integral with the cylinder block and head. The heat absorbed by the water is dissipated to the air through a radiator at the front of the car. The radiator consists of a large number of tubes or cells through which the cooling water flows. Cooling fins are also provided for more efficiently conducting the heat from the water passages to the air. In most cases a fan mounted at the front of the engine provides circulation of air through the radiator during idling and at low car speeds. At high car speeds the forward motion of the car forces sufficient air through the radiator to provide proper cooling. The cooling water may be circulated through the engine passages and through the radiator by thermo-syphon action or may be circulated much more rapidly by means of a pump, usually of the centrifugal type, mounted on the engine. The water-cooled system is, in the final analysis, an air-cooled system, the water acting only as a means for transferring the heat from the engine to the radiator where it is dissipated directly to the air.

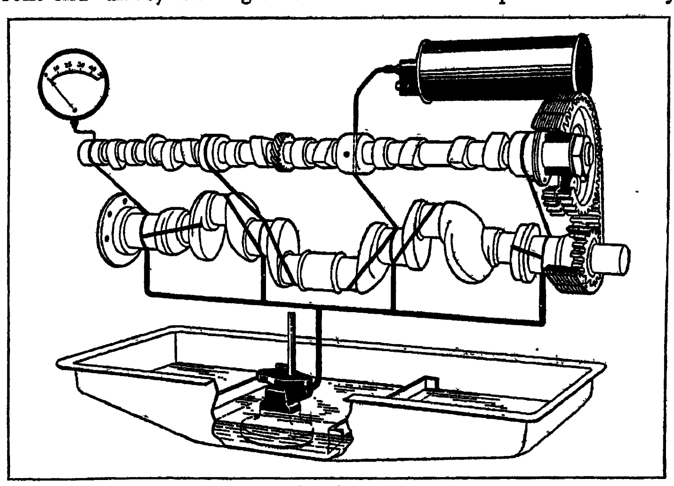
In the air-cooled system the radiator, in the form of copper, steel or cast iron cooling fins, is mounted directly on or cast integral with the cylinder block and cylinder head. In air-cooled automobile engines the cooling fins are generally surrounded by a conduit which provides a closed passage through which the cooling air is drawn over the cylinders by a fan mounted either at the front of the engine or on the fly-wheel. In air-cooled aeroplane engines the propeller blast plays directly upon the cooling fins. Cooling systems employing steam, oil and other media, and evaporative cooling systems making use of the latent heat of vaporization have been used but have not been widely adopted.

During the winter months, with atmospheric temperatures below freezing, an "anti-freeze" solution must be employed in the water-cooled system. Solutions of alcohol, glycerine and ethylene glycol are generally used. In order to heat quickly a cold engine to the proper operating temperature, a thermostatically controlled valve is sometimes located in the water line discharging from the engine to the radiator. With cold water in the cylinder heads the valve remains closed, either blocking the flow of water from the engine or passing it around the radiator. After the water heats up the valve opens, maintaining the water in the jackets automatically at a fixed temperature. Thermostatically operated radiator shutters are also sometimes employed to shorten the warming up period and to assist in maintaining constant operating conditions.

Lubrication System.—The purpose of lubrication is to reduce friction and wear, decrease noise and carry away heat. The most important surfaces of the engine to be lubricated are the frictional surfaces of the pistons, cylinder walls, main and camshaft bearings, connecting rod bearings, wrist pins, timing gears or chains and the valve mechanism. The lubrication of each part is provided for either by delivering the oil through tubes or passages directly to the part to be lubricated, or by depending on lubricant splashed by, or thrown off from, rotating parts. The commonly used lubricants are fluid oils, semi-fluid oils and semi-solids, such as greases. These may be animal, vegetable or mineral oils, but for automobile lubrication, oils derived from petroleum are most generally used because of their suitability and abundance. Oils used for engine lubrication for ordinary driving conditions have a viscosity of 100 to 210 Redwood, or 120 to 250 Saybolt seconds at 130° F. Heavier oils are used for high speed and high temperature operation, and lighter oils for extreme cold weather operation, to permit easy starting.

In the simplest method of lubrication, and one often employed on earlier cars, the lower ends of the connecting rods dipped into oil contained in the crankcase, splashing it to all the bearing surfaces, such as the pistons, cylinder walls, main and camshaft bearings, and camshaft drive. The connecting rods were sometimes drilled so that the force of their impact with the oil would force oil to the bearing surfaces. Difficulty was often encountered with this system due to changes of oil level with oil consumption and with changes of the angle of the car when ascending or descending hills, or on rough roads. These difficulties soon led to the provision of splash troughs under each connecting rod, and a pump or other device to keep each trough constantly overflowing. In this way the engine was rendered less dependent on the quantity of oil in the crankcase for correct lubrication. The model T Ford car furnishes an example of this system.

On many engines, lubrication by the "pressure" system has been provided for the most important bearing surfaces, particularly the main and connecting rod bearings. In these engines usually no splash troughs are provided; an oil pump of the piston or gear type, usually the latter, forces oil under pressure to the main bearings, and sometimes to the camshaft bearings, and, in an overhead valve engine, to the rocker arms. The crankshaft is drilled to conduct oil from the main bearings to the connecting rod bearings. Suitable oil grooves in the bearings allow the oil to flow from the stationary main bearings to the rotating crankshaft. In a few engines an oil line is fastened to the side of the connecting rods, or else the rods are drilled, to convey oil to the wrist pins and cylinder walls. Usually, however, cylinder wall lubrication depends on the oil which is thrown off from the connecting rod bearings by centrifugal force, and which forms a heavy mist within the crankcase. This mist also lubricates the camshaft bearings and cams, valve tappets and front-end drive, although some of these are provided for by



BY COURTESY OF GENERAL MOTORS CORPORATION

FIG. 10.—PRESSURE LUBRICATION SYSTEM

direct oil pressure. Fig. 10 shows a typical pressure system.

Other parts of the automobile to be lubricated are the transmission, differential, wheel bearings, steering gear, springs and chassis bearings. The transmission and differential require oils of viscosity of 68 to 165 Redwood, or 80 to 200 Saybolt seconds at 210° F, except when semi-fluid greases are used. The chassis bearings may be lubricated with either grease or oil. All these systems try to provide a lubricant of some kind between all moving parts. Automobiles must operate under widely different climatic conditions and at different speeds. Most of the lubrica-

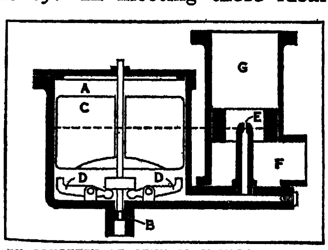
tion problems originate in the difficulty of providing a system that will deliver to all parts the proper amount of lubricant under these different conditions.

CARBURETION AND MANIFOLDING

The engine, properly lubricated and cooled, produces power by converting the chemical energy stored in the fuel into mechanical energy. A system of carburetion and manifolding functions in supplying the proper mixture of air and fuel, which is the source of the engine's power. Carburetion is the art of mixing or blending a liquid fuel with a certain amount of air to form the combustible mixture necessary to meet the required demand. Normally, this is done by a mechanical device known as a carburettor. From the outlet of the carburettor this combustible mixture is carried through an intake pipe or conduit, commonly known as a manifold, to the various cylinders. The carburettor and manifold, together with any other device used in conveying the mixture to the cylinders, make up the induction system of the internal combustion engine. The functions of an induction system are: metering, distribution, acceleration, and starting.

Types of Carburettor.—Three types of carburettors have been employed for internal combustion engines: (1) surface carburettors; (2) wick carburettors and (3) jet carburettors. In the surface carburettor the air passing over the surface or bubbling up through the liquid fuel carried along with it sufficient vapours to make a combustible mixture. This type of carburettor was unsatisfactory as it tended to remove only the lighter fractions of the fuel, leaving the heavier ones. To eliminate this condition the wick carburettor was developed, which also presented a larger surface of fuel to the air stream. Both the surface and wick carburettors have long since passed from the commercial field. A diagrammatic sketch of the simple jet carburettor is shown in fig. 11. Butler is credited with having originated this type of carburettor, although it was first extensively used by Maybach in connection with light oil engines. A nearly constant fuel level is maintained in the fuel bowl *A* by means of the float *C*, which acting through the levers *D* permits fuel to enter through the valve at *B*. The suction stroke of the engine causes air to enter at *F*, pass through the restricted throat in which the fuel jet *E* is located and into the cylinders through the passageway *G*. The restricted throat causes a drop in pressure at that point, and the higher pressure on the fuel chamber *A* causes fuel to flow through the jet *E*. This liquid fuel is picked up by the air stream and forms a combustible mixture.

An ideal carburettor would have the following characteristics: (1) it would correctly proportion fuel to speed and load; (2) compensate for temperature changes; (3) proportion suitable accelerating mixtures; and (4) have low resistance to air flow, to maintain high volumetric efficiency. In meeting these ideal characteristics the simple jet carburettors have been changed until they are now very complex structures. Modern carburettors can be divided into two classes; plain tube and air valve, dependent upon the method of proportioning fuel. The plain tube is similar to the simple jet carburettor in the respect that it depends upon a restricted throat or venturi to proportion correctly the fuel throughout the major portion of its range. The air valve carburettor uses the spring-loaded air valve for the same purpose.



BY COURTESY OF GENERAL MOTORS CORPORATION

FIG. 11.—SIMPLE JET CARBURETION

With the development of automobile engines where operation is necessary over a wide variation of speeds and loads, it was found that numerous additions to the simple carburettor were necessary to obtain satisfactory performance. These changes included the use of auxiliary jets at idle and low part throttle engine speeds, a metering pin which varies the size of the fuel jet, and a fuel well which supplies the necessary enrichment for acceleration. Next came the development of the economizer, which provides rich mixtures for maximum power at full throttle and leaner mixture for maximum economy at part throttle. This is accomplished in one of three ways: (1) by reducing the effective pressure on the fuel jet at part throttle, a method which becomes inoperative at full throttle; (2) by the use of an auxiliary jet which cuts in at full throttle; or (3) by changing the jet size by means of a tapered or offset metering pin. The last important development in carburettors has been the use of an accelerating pump. These pumps are operated by the throttle and provide positive enrichment during the accelerating period.

Manifolds.—As the air fuel mixture leaves the carburettor, it passes into the manifold. An ideal manifold would have the following characteristics: (1) be free from puddling; (2) have low resistance to maintain high volumetric efficiency; and (3) distribute the unvaporized and unatomized liquid fuel evenly to the cylinders. Depressions in the manifold, which permit puddles of raw fuel to collect, may entirely destroy the performance of a carburettor in correctly proportioning fuel to the engine demand. Also puddles may, upon sudden acceleration, be drawn into the engine, causing poor operation. The resistance of a manifold is controlled largely by its size and the character of the necessary bends. While large manifolds are desirable to maintain high volumetric efficiencies, they also reduce the velocities, permitting more puddling. Thus, a compromise must always be effected between these two points.

Present-day petrol includes as many as possible of the crude oil fractions. Thus the end points are being continually changed as new cracking processes and other developments warrant, until now a large portion of petrol fuel can be evaporated only by the use of external heat. This necessitates the use of hot air or hot spots to vaporize a sufficient portion of the fuel to secure adequate distribution. The use of a hot spot is the most desirable way of obtaining good distribution. The liquid fuel in the manifold tends to collect on the walls and absorb heat from the hot spot. This film of fuel also acts as an insulator for the air, keeping the heat away from it and maintaining high volumetric efficiency. Perfect distribution can be obtained only by having all the fuel in a finely atomized or vaporized state. To do this, however, the heat added would greatly decrease the volumetric efficiency. Thus, a compromise must always be effected between the hot spot size and volumetric efficiency.

Superchargers.—To increase the power output for a given-sized engine, superchargers are sometimes resorted to. By this means a greater weight of air-fuel mixture is forced into the cylinders than would be the case with simple induction. The supercharger is a pump capable of handling large volumes of air at comparatively low pressure difference, say about 6 lb., and is located either between the carburettor and the engine or else between the carburettor and the air intake. The supercharger finds its widest application in racing-car practice, where the cylinder size is limited and maximum power must be obtained. A few cars in Europe are equipped with superchargers, but in America superchargers on passenger cars are seldom seen. (*See* SUPERCHARGERS.)

FUEL

Gunpowder was the fuel used in what is thought to have been the first internal-combustion engine. Christian Huygens, a Dutch experimenter, has been credited with trying out that idea about the year 1680; but, for good reasons, his example was not followed in later and more successful engines. Gas was burned as fuel in the first useful internal-combustion engine, built by Lenoir in 1860. Volatile liquids began to be used for internal-combustion engines about 1890, and from the very outset liquid fuels were employed almost exclusively as sources of energy for the automobile engine. Petrol from petroleum has always made up the bulk of automobile fuel. Other liquids, such as benzol and alcohol, and even paraffin, or kerosene and other fuel oils, have also been used, but only in a small portion of the whole. Each American motor car uses, on the average, about 450 gal. of petrol a year; but trucks and buses, which represent less than 15% of all the cars in service, account for nearly one-half of

the consumption. The average passenger car uses only 250 to 300 gal. a year.

Essential Properties.—There are three essential properties that a satisfactory automobile fuel must have: (1) it must contain a large amount of energy; (2) it must be volatile enough to vaporize quickly; (3) it must be reasonably free from tendency to detonate or "knock" in engines. In respect to the first essential property, high content of energy, it is fortunate that petrol made from petroleum contains the largest amount of potential energy per pound of any ordinary liquid that is known. How large this content of energy really is may be seen from the following comparison of the amount of heat produced by burning a pound of petrol with that of some high explosives, which latter are ordinarily thought of as representing energy in its most concentrated form. The figures given are approximate heating values in British thermal units, per pound: petrol 19,000; T.N.T. 6,500; nitroglycerine 3,200; dynamite (No. 1) 2,500; black powder 1,250. The heating value of benzol (benzene) is 17,500 b.th.u. per pound, and that of alcohol (95% ethyl alcohol) is 11,000 b.th.u. per pound. The principal reason why high explosives appear to be so low with respect to petrol in the above comparison is that they contain both a fuel and the oxygen necessary to burn the fuel; but, in the case of petrol, the weight taken is that of the fuel alone. It is for this reason, that a liquid must be vaporized before it can be burned, that a suitable degree of volatility becomes the second essential property of an automobile fuel. A portion of every liquid that makes a satisfactory automobile fuel must vaporize easily enough to make it possible to start an engine in cold weather, and all of it must vaporize readily enough to make the engine run smoothly after it gets under way. The volatility characteristics of a motor fuel are usually measured by distilling 100 cu.cm. of it under carefully regulated conditions (American Society for Testing Materials, Method D 86, 1927).

Knocking.—Freedom from the known tendency to detonate or knock in engines, the third essential property of an automobile fuel, is important for two reasons. The first reason is that the knock, which is the metallic "ping" that smites the ear of the driver sometimes when he is "crowding" his engine in traffic, or when his car is labouring up a hill trying to make it "in high," or top gear, is very unpleasant. The second reason is that a knocking fuel places a definite limitation upon the power and the economy of an engine. If it is to be powerful and efficient, the automobile engine must tightly compress the mixture of air and gasolene in its cylinders, for it is only in that way that maximum expansion can be obtained, and it is the expansion of the burned gases in its cylinders that imparts power to the piston. So the higher the compression ratio of an engine can be made, the greater is its power and the lower its fuel consumption. The actual compression that can be employed in practice however is limited by the tendency of the available fuel to knock, for the knock gets worse and worse the higher the compression is made, and soon a point is reached at which the knock becomes violent enough to cut down power, so that any further increases in compression results in a loss instead of in a gain.

The knocking properties of the average automobile petrol as sold in the United States in 1926 were such that the compression ratios of automobile engines varied from 4:1 up to about 5:1, depending upon the size and the design of the engine. As a result of much research upon detonation in automobile engines, compression ratios are now being increased (1) because automobile fuels are treated to improve their anti-knocking characteristics, and (2) because improvements in engines themselves make them freer from detonation on any given fuel. Four ways have been found of decreasing the knocking tendencies of automobile fuels; viz., (1) adding to the fuel very small amounts of extremely effective materials for preventing knock, such as lead tetraethyl and iron carbonyl; (2) adding to the basic fuel a percentage of another fuel which is comparatively free from tendency to knock. Blends of benzol and petrol and of alcohol and petrol are the most familiar examples of automobile fuels of this second class. Petrols produced in this way usually have good anti-knock qualities; (3) "cracking" heavy petroleum oils into petrol by means of heat, *i.e.*, breaking the large molecules of a heavy oil into smaller and lighter ones (*see* PETROLEUM); (4) selecting crude oils which by nature yield petrol of good anti-knock properties. Petrol obtained from some of the California petroleums, for instance, is much freer from knock than that produced from Pennsylvania petroleum.

Conversion of Heat into Energy Driving the Wheels.—The manner in which the automobile engine converts into motion the heat produced by the burning of fuel in its cylinders is briefly as follows: The gas in the cylinders of the automobile engine, just as everything else in the world, is composed of multitudes of minute particles or molecules. Every one of these molecules is in rapid motion. The hotter a molecule is the faster it moves, and the colder it is, the slower it travels. All of this is the basis of the kinetic theory of heat (*see* KINETIC THEORY OF MATTER), which states that the motion of the tiny particles of which matter is made is dependent on their temperature. The automobile engine first draws into its cylinders a mixture of fuel and air, which is done simply by a downward stroke of the piston away from an open intake valve. That breathed-in vapour consists of billions upon billions of tiny molecules racing about. Next, the piston is pushed up, thereby crowding or compressing the swarming molecules of fuel and air ahead of it into a much smaller space. The result is that several minute particles now batter against the piston top, as they speed about, for each one that did so before; and so the piston feels a much greater push or pressure against it than at the beginning of the compression stroke. At this point a hot electric spark sets fire to the compressed and highly inflammable mixture of fuel and air, and the whole burns very quickly, releasing an extremely large amount of energy in the form of heat. This increases the heat of the mixture, and the motion of those crowded and swarming molecules in the cylinder is speeded up to a terrific velocity. In their violent agitation they beat against the piston top until they thrust it down. The piston, by pushing downward, turns the crankshaft, the crankshaft operates through the clutch and the transmission to turn the driveshaft; and the driveshaft rotates the gears in the differential, the differential gears turn the rear axle, and the axle drives the wheels that roll the car along the road. It is thus that motion of molecules is converted into movement of the automobile. The function of the fuel is to speed up the molecular motion.

ELECTRICAL SYSTEM

The carburetion and manifolding system delivers the proper mixture of fuel and air to the engine. There the chemical energy is converted into mechanical energy through the process of combustion. The ignition system functions in starting this very process by igniting the combustible mixture in the cylinder.

Spark-plugs.—The spark-plug provides ignition of the charge. It consists of an electrically insulated rod surrounded by a shell which screws into a cylinder. Projecting into the cylinder is a pair of short wires, one an extension of the central rod and the other attached to the shell, and between the pair there is a short gap (·02 to ·04 in.) across which the spark passes. These two wires are the electrodes. The electrodes are made of a heat-resisting metal alloy. The outer shell is usually made of steel, threaded on the outside to permit screwing it in place in the cylinder. The insulator, which surrounds the central electrode, is either some ceramic material or mica, and is selected to withstand high temperatures, resist mechanical strains, and to possess high insulating properties. This last requirement is very important for electric current must jump nowhere except across the spark gap. The insulating material must also be a relatively good heat conductor, and proportioned in size and shape to permit the dissipation of heat into the shell. By this means the temperature of the insulator and electrode is kept down to a point where the material itself will not be injured, and is kept below the point where it might cause ignition of the charge at the wrong time. Nevertheless, it is just as necessary to maintain the temperature

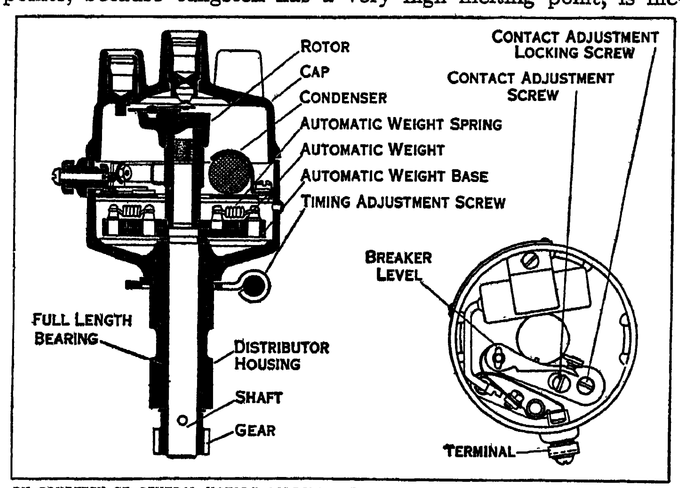
of the insulator sufficiently high to burn any liquid oil or fuel from its surface in order to prevent electrical leakage across the surface. The spark-plug has practically supplanted earlier types of ignition devices, such as hot tubes and make-and-break spark mechanisms, although the latter is still used to some extent in stationary engines.

Ignition System.—In order for the spark to jump the spark gap, a high voltage is necessary. This is obtained either from a magneto or a battery ignition system.

Magneto.—Magneto ignition is used on many European cars and on many aeroplanes where the additional weight of a storage battery is sometimes undesirable. The magneto is fundamentally an electric generator using permanent magnets for the field, and equipped with an integral transformer for the purpose of increasing the voltage to a value high enough to jump the gap in the spark-plug. Either the coils in which the currents are generated may rotate between the stationary field magnets, or the field magnets may rotate within the stationary coils. At the proper time the current which is induced in the primary coils by the relative rotation of the field magnets and the coils is interrupted by means of a circuit-breaker mechanism operated by a cam. A sudden flux change then occurs which induces a current flow in the secondary windings of the magneto, of sufficiently high voltage to jump the gap of the spark-plug in series with this secondary winding. A distributor built integrally with the magneto distributes the secondary current to the various cylinders in the proper order. (*See* also High Tension Magneto.)

Battery Ignition System.—The mechanism of a battery ignition system appears different in form from the magneto, but functions in a very similar way. The engine drives an electric generator. The electric energy generated is either used immediately in the electrical system of the car or is stored in a battery, or accumulator. The ignition system draws on the low voltage battery for an electric current, which passes through an interrupter and through the low voltage winding of a transformer, or coil. Current is induced in the high voltage winding of the same coil and passes through a distributor, and thence through the spark-plug electrodes, jumping the spark gap.

Interrupter or Breaker.—The interrupter is a switch that is periodically opened and closed in synchronism with the vents in the engine cylinder. It is usually equipped with tungsten contact points, because tungsten has a very high melting point, is mechanically hard, resists corrosion to a high degree and is comparatively inexpensive. Formerly platinum was used almost exclusively. A small condenser of about 0·2 microfarads capacity is connected across the contact points to reduce arcing and pitting and also to increase the sharpness of the current break and the intensity of the spark.



BY COURTESY OF GENERAL MOTORS CORPORATION

FIG. 12.—DISTRIBUTOR

Coil.—The ignition coil consists of an iron core, a primary winding and a secondary winding. The core is a bunch of iron wires or thin strips. The primary low voltage winding consists of comparatively few turns of comparatively large wire, wound around the core. The purpose of the primary winding is to build up a magnetic flux through and around the core. The secondary or high voltage winding consists of a large number of turns of fine wire, also wound around the core. When the interrupter or breaker is closed, the low voltage electric current flows through the primary winding of the ignition coil and sets up a magnetic flux in and around the core. When next the interrupter is opened, the low voltage electric circuit is opened and the current stops flowing through the primary winding. The magnetic flux which had been set up in and around the iron core now immediately collapses. This collapse of the magnetic flux induces a voltage in the secondary winding, causing a current to jump the gap in the spark-plug. Several thousand volts are required to cause a spark to jump across the gap in the spark-plug, whereas the battery voltage is usually 6 or 12 volts. The voltage in the primary winding of the coil is therefore 6 or 12 volts, but the voltage induced in the secondary winding of the coil is many thousands of volts. The coil functions increase the voltage available in the battery to the voltage required by the spark-plug, although at the same time the process results in a reduction of the current.

Distributor.—The distributor rotates and distributes the secondary current from the coil to the spark-plugs at the proper time and in the proper sequence. A typical distributor is shown in fig. 12. The case is usually made of some moulded insulation material such as bakelite, resistive to the action of moisture, heat, acids and oils.

Timing.—Shortly before the piston reaches the upper end of its travel on the compression stroke, ignition occurs. Due to the fact that an appreciable time is required for the charge to burn, the timing of the spark to produce maximum turning effort on the crankshaft is required to be somewhat in advance of the top centre position of the piston. This advance varies with speed. In general, less spark advance is required at low speeds and more at high speeds. Automatic governors are commonly provided inside the distributor housing to adjust the advance to approximate engine requirements at all speeds. In addition to this automatic advance, suitable controls are usually provided to enable the driver to advance or retard the spark.

Generators and Storage Batteries.—The purpose of the electric generator (*q.v.*) is to transform mechanical energy from the engine to electrical energy which is used in the various electric units of the car, either directly or reserved for later use by means of the electric storage battery, or accumulator. The conventional generator is an ordinary direct current two- or four-pole unit equipped with a shunt field. In case of the two-pole generator it is common practice to mount a third brush adjustably in a position between the two other brushes so that when the speed and load on the generator increase and the field shifts, the third brush will collect a diminishing current supply for the field. In this manner the battery charging rate may be kept at a high value at low speeds and be prevented from rising to abnormal values at high speeds.

Starting Motor.—The function of a starting motor is to set the moving parts of an engine in motion at sufficient speed until the engine starts operating under its own power. Engine cranking speeds of above 35 r.p.m. are usually required for successful starting in cold weather. Starting motors are generally of the six-volt series-wound type. They are equipped with a special coupling which permits the engagement of a small gear on a shaft extension of the motor with a ring gear either cut on or attached to the fly-wheel. This gear reduction makes possible a starting motor speed 10 or 12 times as great as the engine speed during cranking, with a consequent multiplication of torque. Starting motors are designed with a low internal resistance in order to utilize to full advantage the energy contained in the storage battery.

There are a number of different types of engagement couplings. The automatic coupling is of the inertia type. The small gear is mounted on the armature shaft through a steep spiral thread. The rotational inertia of the gear prevents it from turning when the motor armature begins to rotate, and it is therefore moved toward the fly-wheel ring gear. The teeth are so chamfered both

FIG. 13.—SECTIONAL VIEW OF STARTING MOTOR

lightly in place by means of a spring. Further motion of the foot lever compresses this spring until the lever closes the starting motor switch. The pinion then revolves slightly until engagement is effected and cranking of the motor follows. An over-running clutch disengages the starting motor when the engine starts. Fig. 13 shows a typical starting motor.

Lighting.—Automobile head-lighting practices differ very materially in the different countries. These differences arise chiefly from the fact that no system of head-lighting has yet been developed which satisfactorily meets all of the requirements of the various driving conditions. In localities where roads are straight and traffic is light, cars may be operated at relatively high speeds, and drivers will be interested primarily in seeing obstructions, turns, etc., far down the road. In other localities where the roads twist and turn and traffic is heavy, much lower speeds will prevail. Here drivers do not need to see nearly as far ahead but require more light to either side to illuminate roadsides and ditches and to show the way around turns. Some satisfactory means is also needed to pass other cars safely and without dangerous glare. Where cars are driven from one part of the country to another and encounter a wide range of driving conditions, the head-lighting system adopted for general use must take the form of a compromise designed to provide for reasonable safety and comfort under all conditions of driving.

In the United States, where the traffic problem has been difficult for some years, head-lighting has received a large amount of attention. The trend of development has been influenced to a considerable extent by the recommendations of technical societies and by the laws in the various States. These systems of head-lighting in general use require that the beam be adjusted in such a manner as not to permit the high intensity rays to rise above the level of the head-lamps under ordinary conditions of operation. A small amount of light is required above the head-lamp level to reveal overhanging obstructions and objects, the lighter coloured or bulkier parts of which are above the level of the lamps, but this part of the light should be closely limited so that it will not dazzle approaching drivers to a dangerous extent. In the United States head-lamps are designed to produce a beam which has the form of a horizontal band of light when projected on a vertical surface. The top of this beam is aimed at or slightly below the horizontal. The highest intensity is near the top of the beam where it is needed to reveal objects several hundred feet ahead. This high intensity section extends to both sides sufficiently to light the road well ahead of the car in rounding turns. A relatively small amount of light is needed in the immediate foreground and well to both sides to show up inequalities in the road surface, roadsides and ditches.

On smooth, level roads, head-lamps adjusted in this manner are fairly satisfactory. Drivers may pass each other at relatively high speeds without dimming and in comparative safety. Unfortunately, however, all roads are not smooth and level. The angular difference between the eyes of an approaching driver 100 ft. ahead and objects which one must see on and above the road is so very small that it does not require a great change of gradient to lift the blinding part of the beam into the other driver's eyes. Car springing is another source of trouble. On rough roads the action of the springs raises and lowers the beam so as to direct a series of flashes into the eyes of an approaching driver. Also, in cars having both front and rear seats, loading must be considered. When the rear seat is loaded, the beams may be raised as much as 2 ft. at a distance of 100 ft. ahead. For this reason it has been customary to aim the beams with the car loaded. This, of course, interferes seriously with the range of visibility ahead when the rear seat is empty. The tendency toward lower drivers' seats, softer springs and balloon tires in the United States and elsewhere, has aggravated these troubles.

Because of these inherent deficiencies in fixed-beam head-lamps, dual-beam head-lamps have come into general use during the past few years. The double-filament incandescent lamp is used in practically all dual-beam head-lamps supplied on American cars. By switching from one filament to the other the driver may raise or lower the beam at will. The upper beam should be aimed up to the horizontal to illuminate objects far down the road. The lower beam is tilted downward about two degrees. This avoids dangerous glare under ordinary conditions of driving. The beam projects a high intensity on the road to a distance of about 100 ft. ahead of the car, which is desirable for passing other cars with glaring head-lights. This beam may be used continuously with safety in the city where street lights illuminate objects several hundred feet ahead. The lower beam is also very satisfactory for continuous use in traffic where the road is illuminated by the headlights on other cars.

MOTOR CAR OPERATION TERMINOLOGY

In the development and testing of automobile equipment certain engineering terms are used that are frequently misunderstood and misinterpreted. (*See* INTERNAL COMBUSTION ENGINES.) These terms are: mean effective pressure, work, torque, power, thermal efficiency, mechanical efficiency and volumetric efficiency.

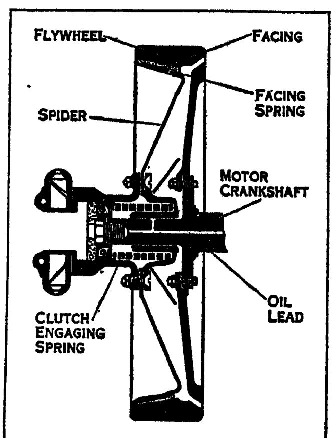
Pressure is generally used in referring to the force of the gases on the piston, and the force between two bearing surfaces. It is commonly measured in pounds per square inch. For some purposes it is convenient to refer to a theoretical average pressure such that, if it acted on the piston throughout the expansion stroke, would produce the same amount of work as the actual varying pressure. This theoretical pressure is known as the *mean effective pressure* (m.e.p.). *Work* denotes the transfer of energy from one place to another. It is defined as a product: of force and distance. The engineering measures of work are the foot-pound and inch-pound; *i.e.*, force in pounds multiplied by distance, in feet or inches, through which the body, on which the force is applied, moves. From a scientific point of view no work is done unless the force applied to a body moves the body. In other words, no energy is transferred unless there is movement of the body into which we are trying to put the energy. *Torque* is merely a technical name for twist. It is different from work in that it does not take into consideration the distance through which a force acts. Torque might also be defined as a special case of linear force where the force is so placed with respect to the body as to produce only rotary motion of the body. Its measures are the pound-foot and the pound-inch. At the speed of maximum power the torque is only about two-thirds or three-fourths as great as its maximum at a lower speed, generally 800–1,600 r.p.m. American automobile engines develop from 90 pound-feet of torque to over 350 pound-feet.

Power.—Power may be defined as the rate of doing work.

The common measure of power is the horse-power, which may be defined as the rate of doing work which is equal to 550 foot-pounds in one second or 33,000 foot-pounds in one minute. Another way of saying this is: the rate energy is transferred so many foot-pounds per second or per minute, or so many horse-power. Power (rotary motion) must consider force, distance and time, which is expressed for convenience as torque (force) and revolutions per minute (distance and time). If the torque of an engine should remain constant, the power developed would be twice as great at double the speed. The power of an engine is commonly measured on a dynamometer (*q.v.*), which in some cases is a special electric generator with certain arrangements to permit measuring the torque developed at the crankshaft. This torque, combined with the speed of the engine, gives a measure of the power available for doing work, which is called the *brake horse-power* (b.h.p.). The b.h.p. of an engine increases with speed up to a certain speed, above which it decreases. For American cars this speed varies from 2,000 r.p.m. to over 3,600 r.p.m., the majority being about 2,800 r.p.m. The maximum b.h.p. developed by these engines varies from about 35 to over 120.

Brake horse-power is sometimes confused with the horse-power rating often used for taxation purposes. Various countries use a formula based on the physical dimensions of the engine to determine a theoretical horse-power figure for computing the tax. In the United States and Great Britain the same formula is used (called the N.A.C.C. formula for the U.S., and the R.A.C. formula for Great Britain) based on the diameter and number of cylinders: h.p. $= \frac{D^2N}{2\cdot 5}$ when D is the diameter of the cylinder in inches, and N is the number of cylinders. This formula gives a figure which is from one-half to one-fourth of actual b.h.p. developed by modern engines. Another formula is: h.p. $= \frac{D^2NS}{10}$ where S equals the length of the stroke. This formula is used in some parts of the United States.

Efficiency.—*Thermal efficiency* is the ratio of the work output of the engine, expressed in terms of heat, to the total amount of heat in the fuel used to secure that amount of work. A normal engine has a thermal efficiency of from 15 to 22% at full load. (*See* MOTOR CAR: *Fuels and Combustion;* INTERNAL COMBUSTION ENGINES.) *Mechanical efficiency* is the ratio of work output of the engine to the work developed within the engine cylinders. The difference is accounted for by the friction and pumping losses within the engine itself. Of the various friction losses, the piston friction is the largest. Considerable work is also expended in pumping the gases into and out of the cylinders, particularly at part throttle. Automobile engines vary from 75 to 93% mechanical efficiency at full load.

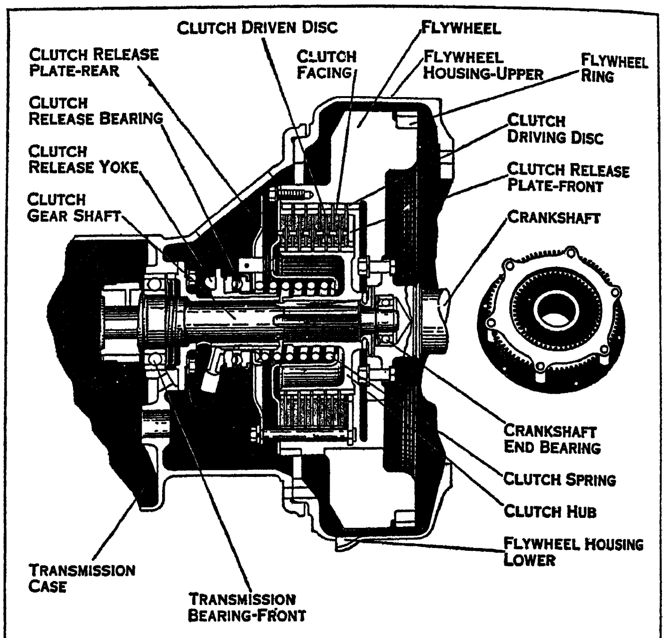


BY COURTESY OF GENERAL MOTORS CORPORATION

FIG. 14.—CONE CLUTCH

To decrease the friction losses in an engine, bearing materials with low-friction properties have been developed, and also more thorough lubrication of moving parts has decreased friction to as low a figure as seems feasible with present design of engines. The pressures developed at the bearing surfaces have necessitated certain minimum limits for bearing sizes, with due regard for durability. While the bearing friction losses for a given size of engine have been decreased but little, the mechanical efficiency in many cases has been increased by increasing the power output of the engine without a corresponding increase of friction. (*See* section, *Metals in the Motor Car.*) *Volumetric efficiency* is the ratio between the volume of air drawn into the engine for each two revolutions (one cycle), and the engine displacement, or volume of the cylinders swept by the pistons.

Loss of Energy.—In the operation of an automobile, more power is required to bring the vehicle up to any predetermined speed than to keep it moving at that speed (except the maximum speed of the automobile). The difference between the power of the engine at any speed and the power required to drive the automobile at a speed corresponding to this engine speed on level roads, represents the power available for acceleration and hill climbing. To increase this difference, for starting purposes and on other occasions when greater power is needed, the change gears in the transmission are used. (*See* section, *Transmissions.*) Nearly all cars have their rear axle gear ratio so chosen that the engine will develop very nearly its maximum power at approximately 75% of the maximum speed of the car when in direct drive. Then the maximum hill-climbing ability or the maximum accelerating ability will come at the speed of maximum torque, or for most American cars, about 20 to 25 m. per hour.



BY COURTESY OF GENERAL MOTORS CORPORATION

FIG. 15.—MULTIPLE DISC CLUTCH

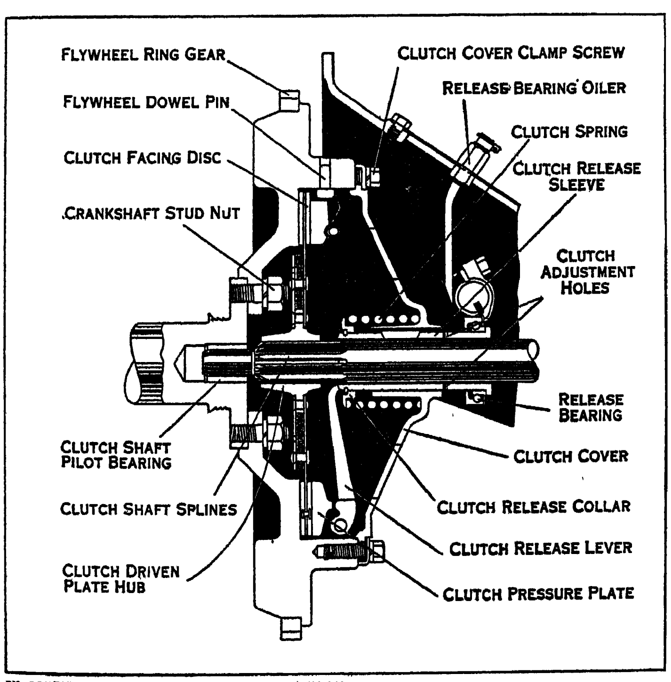
The power required to drive an automobile on a level road is utilized to overcome two resistances to motion—rolling or friction resistance, and air resistance. The rolling resistance is caused by friction in the transmission, universal joints, differential, rear wheel and front wheel bearings, and also of the tires on the road. The air resistance is caused by the pressure of air against the front of the car and the partial vacuum behind it, and by the friction of the air as it passes over the various surfaces. The rolling resistance is more or less constant, regardless of the speed, while the air resistance increases as the square of the speed. In other words, at 60 m.p.h. the air resistance is four times as great as it is at 30 m.p.h. At low speeds, say 15 to 20 m.p.h., the air resistance forms the smaller part of the total, say about a quarter, while at higher speeds, the air resistance increases very rapidly, so that at 60 m.p.h. it accounts for two-thirds or more of the total resistance.

TRANSMISSION

The engine, with its lubrication and cooling, and the carburetion and ignition systems, function as a unit to produce power, and are commonly known as the power plant. In addition, a mechanism is necessary to transmit the power produced by the power plant to the wheels of the vehicle in order that they, rotating, may push the car along the road. This mechanism is the transmission, and it consists of several units: (1) the clutch, (2) the gear-set, gear-box or transmission, (3) the propeller shaft and universal joint,

(4) final drive, differential, rear axle.

Clutch.—The clutch enables the operator to connect or disconnect at will the engine and the mechanism used for transmitting the motive power to the driving wheels. The clutch is disengaged when one desires to stop the vehicle without stopping the engine, or when it is necessary to change the ratio of the gear in the transmission. Of the many forms of clutches that have been used, the three types—the cone, fig. 14, multiple disc, fig. 15, and single plate, fig. 16,—have been used more than any others. The cone clutch is made up of a short portion of a cone with an included angle of about 12° to 15°, and is usually faced with leather or asbestos fabric. Provision is made so that this cone can be moved axially in and out of contact with a corresponding conical surface in the engine fly-wheel. A spring or springs are employed to keep the clutch engaged with the fly-wheel when it is not held out of engagement by the operator. The multiple disc clutch is made up of a plurality of plates or rings, half of which, called the driving discs, are connected by splines to the fly-wheel, the other half being similarly connected to the main drive shaft of the transmission. Sufficient spring pressure is provided so that the friction between the driving and driven disc surfaces will transmit the full power of the engine without slipping. The single plate clutch, on account of its simplicity and ease of manufacture, has largely superseded all other forms. This clutch is made up of a single plate which is keyed to the transmission main drive gear shaft and is usually spring-clamped between a flat surface on the fly-wheel and a pressure plate arranged so that it is also driven by the fly-wheel. The required pressure to prevent slipping is provided, either by a plurality of springs at the back of the pressure plate,



BY COURTESY OF GENERAL MOTORS CORPORATION

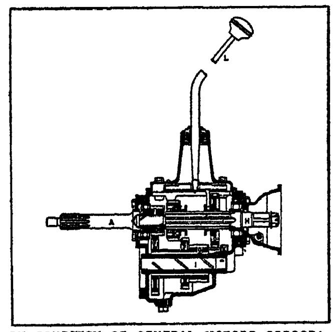
FIG. 16.—SINGLE PLATE CLUTCH

or a single spring multiplied by levers fulcrumed in the fly-wheel or pressure plate, and acting against the other members.

General Requirements for Transmission.—"Best car performance" requires a power plant capable of driving the road wheels to the verge of slipping during acceleration and at maximum car speed. An internal combustion engine could be built powerful enough to approach these conditions; such an engine would have a slipping clutch, a properly selected rear axle ratio, and it would drive the wheels directly. Considerations of weight, space limitations, cost, economy of operation, and sometimes excessive taxation, however, prohibit the use of such a large power plant, making it necessary to use a smaller engine.

An internal-combustion engine delivers its maximum power at a definite engine speed. Therefore, for best performance it is desirable to maintain this definite engine speed constant regardless of car speed. For normal driving conditions on level roads, however, the power required is less than the maximum power supplied by the engine, and for this condition it is desirable to run the engine at a much lower speed in order to give economy of operation. To fulfill these two conditions—maximum power and economy—it is necessary to incorporate between the engine and the road wheels a device which will permit a change of the ratio of engine speed to car speed. This is called the transmission. An ideal transmission would fulfill the above two conditions completely, but at present mechanical difficulties, cost, size, weight and complicated operation, make such an ideal transmission impracticable. In actual practice, therefore, transmissions are a compromise between the ideal and the limiting factors.

Gear-set, Gear-box, (Gear) Transmission.—The most common type of transmission is called gear-set, gear-box, or gear transmission, and comprises a housing or case with shafts and bearings to carry the necessary gears, usually of the spur gear type. In the greater number of transmissions the gears are so arranged that by proper selection either three or four ratios of engine speed to car speed for forward driving, and one ratio for reverse driving, may be obtained. A typical three-speed forward and reverse transmission is shown in sectional view in fig. 17, in which *a* is the driving shaft and clutch member, *h* is the driven or spline shaft, *i* is the countershaft, *b* and *e* are constant mesh gears. The shaft *i* is stationary and gears *e, f* and *g*, fixed together, rotate on shaft *i*, whenever the clutch is engaged and the engine running. To engage the low gear, the shifter lever *l* is moved so that gears *g* and *d* are brought into mesh. The torque is then transmitted from gear *b* to gear *e* and through gears *g* and *d* to the spline shaft and universal joints to rear axles and road wheels. When in low gear, the engine revolutions are from 10 to 15 times the revolutions of the road wheels, a condition which causes the vehicle to move forward slowly, but with considerable force, as is required when starting, climbing a steep hill or pulling through sand or mud. To engage second, or intermediate gear, the gear shifter handle is moved so that gears *c* and *f* become engaged. When in second gear, the engine makes from 7 to 12 revolutions to 1 revolution of the road wheels, a condition which causes the vehicle to move faster than when using low gear, but with less force. To engage direct gear, the internal clutch teeth in *c* engage the external clutch teeth on *b*, and the torque is transmitted directly to the main spline shaft and on through to the road wheels. When in direct, or high, gear, the engine makes 3 to 5 revolutions to 1 revolution of the road wheels, a condition which gives high speed and best economy. To reverse the vehicle, sliding gear *d* is moved into engagement with idler gear *k*. Torque is then transmitted from shaft *i* to the idler gear *k* and from *k* to gear *d*, which drives shaft *h* in a reverse direction.



BY COURTESY OF GENERAL MOTORS CORPORATION

FIG. 17.—SECTIONAL VIEW OF THREE-SPEED FORWARD AND REVERSE TRANSMISSION

Planetary Transmission.—This transmission was extensively used early in the automobile industry, but due to its complication, particularly when more than one reduction ratio is desired, and subsequent cost, it has been practically abandoned. It receives its name from the fact that an end view is similar to a solar system having a sun gear and a series of planet gears rotating about it. The two most simple types consist of direct, low and reverse speeds, one type being made up of all external gears and the other made up of external gears and one internal gear. By selecting various numbers of gear teeth any ratio can be obtained from 2 to 1 up, within practical limits. Several reduction ratios can be built into the same unit by the addition of more combinations of gears.

Infinitely Variable Transmissions.—An infinitely varia transmission provides a continuous range of transmission rati

within selected limits. Thus any transmission ratio most suitable for a particular driving condition may be selected, giving best car performance for a predetermined engine size. Moreover, noise, time loss and effort experienced when shifting gears in an ordinary transmission are eliminated and adaptability for automatic control is increased. These advantages were recognized early, but complexity, weight, cost and low efficiency have limited the use of such transmissions to a small field where performance and smoothness are paramount and the objectionable features are of secondary importance, as for instance in American motor-bus and rail-car operation. Friction drive was among those first utilized. Early types used a belt and two conical pulleys. Friction discs using wood, leather or fabrics on the driving surfaces, or metal to metal contact, have been tried on small cars with limited success. Variable throw mechanisms oscillating intermittent members which in turn drive through devices simulating ratchets are used in the De Lavaud transmission. The intermittent action of the several individual members combine in a continuous driving effort. Other transmissions use the inertia reaction of weights oscillated by a constant throw mechanism, the inertia reaction driving through ratchets or similar devices.

Hydraulic transmissions use an engine-driven pump, delivering an arbitrarily variable amount of fluid to an hydraulic motor operating the driving wheels. In electric transmissions an engine-driven generator supplies current to electric driving motors. In some arrangements the structural parts of generator and motor have been combined to reduce weight and cost. Electric transmissions are widely used in American motor-buses and on a few trucks. By combining an infinitely variable transmission with an epicyclic gear, part of the torque may be transmitted through gears, thus reducing weight and costs of the variable mechanism and increasing efficiency. Besides this, two ratios may be obtained at which the variable mechanism does not perform any relative motion. In general, the control of transmission ratio may be inherently automatic, governor operated, manual, or a combination of these. Automatic control may be based on engine or vehicle speed, road torque requirements or combinations thereof. Only a few passenger cars at present use any of these forms of infinitely variable transmission, because when cost, weight, size, complication and general reliability are considered, the manually operated sliding gear transmission is more practical than any infinitely variable type so far developed. At the present time the electric transmission used on American motor-buses is generally not considered suitable for passenger cars.

Propeller Shaft and Universal Joints.—The shaft which transmits the power from the gear-box to the rear axle is called the propeller shaft. Since the rear axle in the usual design of car moves up and down with the wheels relative to the car itself, it is necessary that this shaft incorporate some means to allow the shaft to assume varying angularities and revolve at the same time. This is done by means of universal joints. There are two general types of propeller shafts, depending upon the manner in which the rear axle is attached to the car. In the torque tube drive, the rear axle housing is extended in the form of a tube surrounding the propeller shaft, and this tube is flexibly attached to the rear of the gear-box or to some point on the frame adjacent thereto, so that the rear axle, in moving up and down, rotates about this joint. In this case only one universal joint placed coaxially with the point of attachment of the torque tube is required. In the so-called "Hotchkiss" drive, the rear axle is fastened rigidly to the springs, and moves up and down without rotating about the wheel axis, in which case it is necessary to have two universal joints, one at each end of the shaft, and a sliding connection to allow the shaft to change its length to allow for movement of the rear axle about a centre not coaxial with either joint. Some cars have a beam or "radius rod" which performs the function of locating the rear axle, in which case two joints are invariably employed.

Universal joints are used to transmit torque from one shaft to another through an angle. Where loads and speeds are high, this angle must be small, not over 6 to 8°, although for light work angles of up to 30° are practical. Many types of universal joints are used, but the most common are the mechanical "Cardan" joint and the flexible type. The former consists essentially of two forked members, one on each of the two intersecting shafts, so disposed that a pin between the two "prongs" of each fork will pass through the point of intersection of the shafts. The two pins form a rigid cross which transmits the torque from one fork to the other regardless of their relative angle. The flexible type of universal joint consists essentially of two similar forks with a ring of flexible material, usually a rubberized fabric between them, and the relative movement of the two forks is taken up in the flexing of the ring.

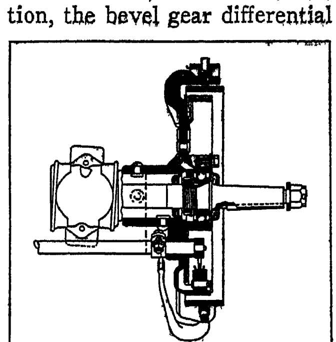
FIG. 18.—SPIRAL BEVEL GEAR, REAR AXLE ASSEMBLY

Rear Axle and Final Drive.—When the axis of the power plant is disposed longitudinally, the final transmission has to provide a right-angle drive combined with the necessary reduction of rotational speed; this may be effected in various ways, of which at the present time the bevel gear and the worm drive are principally adopted. The bevel gears used at present are mostly of the spiral bevel type, the straight bevel being almost obsolete for passenger vehicles. The torque is transmitted from the propeller shaft to the final drive and from the final drive to the main shafts, and is equalized between the shafts by means of the differential.

Worm Drive.—The worm drive is used quite extensively and has made progress in the United States, several makers having adopted this drive for passenger car use in recent years. The chief advantages are quietness of operation, permanence of adjustment and freedom from vibration. This construction with underslung worm also permits considerable lowering of the chassis.

Axle Differential.—The axle differential divides equally between the driving wheels the effort supplied by the engine and at the same time allows one wheel to overrun the other when turning corners. The most common method of doing this is by means of a combination of bevel gears. Spur gears, worm gears and different combinations of pawls and ratchets have been employed at various times, but because of its low cost and satisfactory operation, the bevel gear differential is most generally used.



BY COURTESY OF GENERAL MOTORS CORPORATION

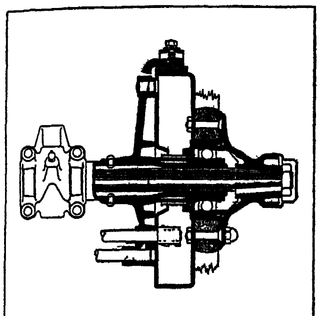
FIG. 19.—REAR AXLE, SEMI-FLOATING TYPE

The bevel gear differential may be described in the following manner (*see* fig. 18): The gears are carried in a differential case A which has fastened to it the driven final drive gear B. Two bevel side gears C and C' are placed opposite each other and attached one to each axle drive shaft D and D', and are free to rotate in the case. Two (or more) equally spaced bevel pinion gears E and E', also free to rotate, are carried by means of a stub-shaft F fastened in the case and meshed with the side gears C and C'. The turning effort is transmitted to the case A and stub-shaft F, and in turn to the pinion gears E and E', which divide it between the two side gears C and C' in the manner of a simple beam loaded in the centre and restrained at each end. The only serious disadvantage of the bevel and spur gear type appears when one rear wheel loses traction; *i.e.*, starts to slip as in deep sand or mud; the wheel without traction will spin and the other will stand still, giving no motion to the vehicle. This can be overcome by introducing internal friction or locks, but in most

cases the disadvantages of these methods outweigh the advantages.

Rear Axles.—The three types of rear axles are classified according to the shaft construction, as the semi-floating, the three-quarter floating and the full-floating.

Semi-Floating.—In the semi-floating type of rear axle the axle shaft is supported on two bearings, one at the outer end of the housing and one at the differential end, and the wheel is keyed rigidly to the shaft, which in addition to transmitting the driving effort sustains the weight of the car and resists all external thrusts, such as are due to skidding or to turning corners (*see* fig. 19).



BY COURTESY OF GENERAL MOTORS CORPORATION

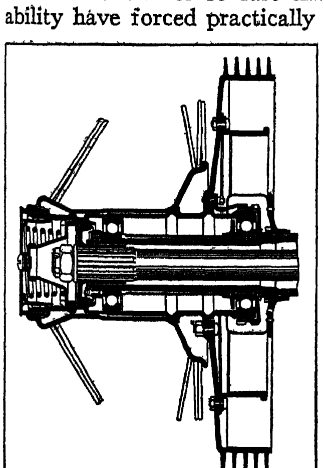
FIG. 20.—THREE-QUARTER FLOATING AXLE

Three-Quarter Floating.—In the three-quarter floating type of rear axle the inner end of the axle shaft is supported in the same manner as in the case of the semi-floating axle. The outer bearing, however, supports the wheel, which in turn is rigidly keyed to the outer end of the axle shaft. In this type of axle the car weight is carried by the housing, but the side thrusts due to skidding and to turning corners, in addition to the transmission of the driving effort, are still carried by the axle shafts (*see* fig. 20).

Full-Floating.—In the full-floating type of rear axle the wheels are carried by double bearings on the axle housing, which, therefore takes all stresses except that of the driving effort. The wheel is not keyed rigidly to the axle shaft but is driven through splines by means of a splined flange on the axle shaft (*see* fig. 21).

THE CHASSIS

Brakes.—The brakes are called upon to perform two duties, one of which is to bring the car to rest or to decrease its speed, and the other to hold the car in its place while unattended. These two functions are ordinarily performed by two separate braking systems, the former function by a foot pedal operated system, called the "service" brake, and the other by a hand-operated brake, called the "parking" or "emergency" brake. The modern car moves so fast that the demands for rapid stopping ability have forced practically every make of motor car to have a separate brake for each of the four wheels, and a modern motor car can stop from a speed of 60 m. per hour in 200 ft. or less (the distance depending on the condition of the road and the tires). Maximum deceleration rates generally are about 18 to 20 ft. per sec., but depend to a large extent on the condition of the road surface and the tires.

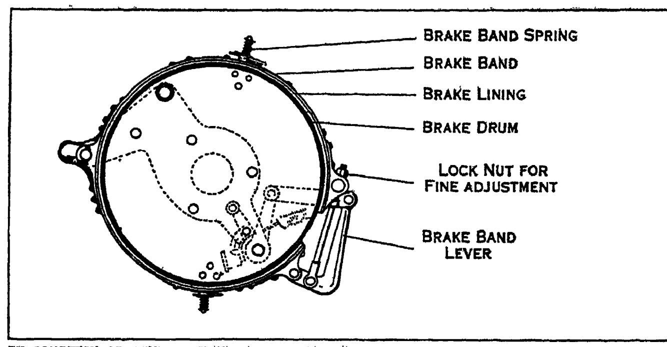


BY COURTESY OF GENERAL MOTORS CORPORATION

FIG. 21.—FULL FLOATING AXLE

Brakes may be divided roughly into two classes—the external contracting and the internal expanding brakes. Fig. 22 shows the external type, and fig. 23 shows the internal type. The former type consists of a band attached to the stationary part of the axle, and acting on the outer surface of a drum attached to the wheel. The internal expanding brake uses a similar drum, the inner surface of which is gripped by two or more shoes which are forced outward by the driver through a suitable mechanism connected to the brake pedal or lever; in some installations a flexible band is used, which is forced outward against the drum by separating its ends.

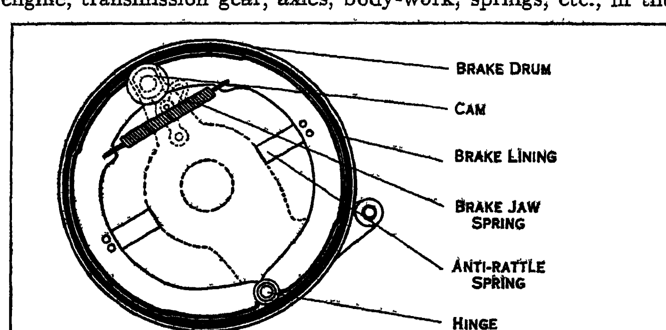
Two general methods of operating the brakes are commonly used—mechanical and hydraulic. In the mechanical systems motion of the brake pedal is transferred to the brakes at the wheels by means of rods or cables, with suitable shafts and levers to compensate for the motion of the wheels relative to the frame and sometimes to equalize pressure between the different brakes. In the hydraulic system, used on some cars for the service brakes, motion of the brake pedal applies the brakes through an oil pipe to each wheel. A master cylinder and piston is actuated by the pedal, and the oil displaced from this cylinder is forced through a system of conduits to each wheel, where it actuates the pistons in such a way as to apply the brakes. A mixture of glycerine and alcohol is commonly used for the liquid; this mixture changes in viscosity but slightly with change of temperature, and freezes far below any usual operating temperature of the car. Suitable means are provided to refill automatically or manually the liquid lost from the system. A brake is often fitted to the drive shaft which acts on the rear wheels through the driving mechanism. Since the retarding forces are in general more severe than the driving forces, use of this brake involves a certain amount of extra wear and tear on the driving gear, and for this reason it is most often used only as a parking brake. The shoes or bands which press against the brake drum are ordinarily faced with some material having a high value of friction. This is ordinarily made of woven asbestos, which is treated with various materials to act as a binder and to secure desirable friction characteristics.



BY COURTESY OF GENERAL MOTORS CORPORATION

FIG. 22.—EXTERNAL BRAKE

Frame, Front Axle and Steering Gear.—The desirability of making the mechanism of the car independent of the style of passenger accommodation was apparent as soon as motor cars were made in any considerable numbers. Accordingly, the frame, which forms the backbone of the car, has become practically universal, and to it are fastened all of the car's principal components. It is the function of the frame to keep these components, the engine, transmission gear, axles, body-work, springs, etc., in their proper relative positions. The type of frame which has become practically standard, consists of two longitudinal beams, usually pressed-steel channel sections, with cross members spanning between them at intervals. Brackets are provided for the mounting of the various parts of the car. The frame with the mechanical parts of the car assembled upon it is called the chassis. Due to inequalities of road surface there is considerable tendency to distort the frame, which places strains upon the mechanism and body-work; so it is important that both longitudinal and cross members be of stout construction to avoid bending and twisting.



BY COURTESY OF GENERAL MOTORS CORPORATION

FIG. 23.—INTERNAL BRAKE

The side members are almost always of pressed steel and are from 4 to 8 in. in depth, of material from $\frac{1}{8}$ to $\frac{3}{16}$ in. in thickness. The cross members may be of almost any section, but are most commonly either channel or tubular. Departures from this type of construction, which are very few, use wooden frames, combine the functions of body and frame, or substitute tubular longitudinal members.

The front axle supports the front end of the car as its name implies. It is a steel beam, usually of I or tubular section, which joins the front wheels of the vehicle; and is ordinarily attached to the frame of the vehicle through springs. These springs prevent the irregularities and shocks from the road being transmitted to the car and passengers. Instead of turning with respect to the vehicle, as in the case of the horse-drawn carriage, the axle of the motor car is always fixed in attitude and direction, and the vehicle is steered by moving the wheels about pivots vertically disposed at the ends of the axle. On some motor cars the front axle is omitted, and each wheel is independently attached to the car frame.

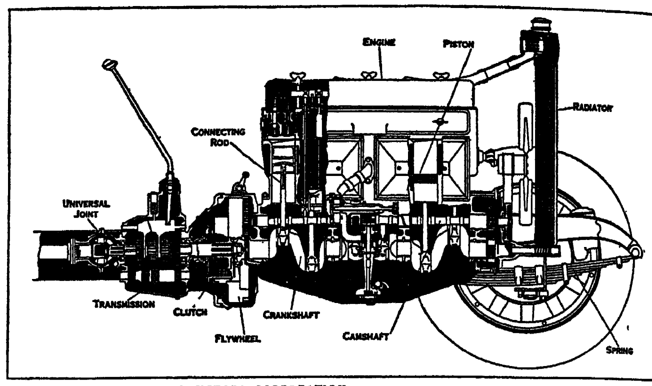
The car is steered with a hand wheel which is connected to the steering pivots by means of gears and linkages. The steering gear, as this system is called, may be any one of quite numerous forms of construction. The rotation of the hand wheel is communicated to a horizontal shaft at the base of the hand wheel, or steering column, through a worm gear, screw or cam mechanism. A lever at the end of this horizontal shaft transmits the turning motion, through an intervening link, to a pivot on which a front road wheel is mounted. The other front wheel is also mounted on a similar pivot and the two pivots are linked together by means of a cross rod so that the two front wheels move simultaneously, keeping their proper relative position.

Springs and Riding Quality.—Laminated leaf springs have been almost universally used on motor vehicles for the chassis suspension system. The semi-elliptic type is the one in most general use, being found on about 97% of all the makes of cars now in production. Many of these use the Hotchkiss drive in which the spring transmits the driving force and resists the braking torque, thus eliminating the torque tube required when other types of springs are used. When the Hotchkiss drive is used, the springs are often designed to be nearly straight under average load so that the driving force is directed along the spring.

The springs are usually mounted on the axle, being attached thereto by means of spring plates and U bolts. In the designs using semi-elliptic springs, the front end is usually attached to the frame by means of a pin joint and the rear end by means of a swinging shackle which allows for the change in length as the spring is straightened under load. The cantilever type, used on many "luxury" cars, is merely an inverted semi-elliptic spring having the centre attached to the frame by means of a trunnion bearing and the front end attached to the frame by means of a swinging shackle, the free end resting upon the axle with a pin joint. In order to eliminate the lubrication required by these pin joints, other types of mountings using rubber extensively are being experimented with and a few of these are now in use. Originally, the leaf springs were made of plain carbon steel. The ends of the leaves were tapered and had various shapes designed to prevent localized stresses.

In manufacture, the leaves are usually formed to the same inside curvature, thus causing a space between each pair of leaves as they are placed together. This space, termed "pull," causes the leaves to remain together even though the spring rebounds to its free position after deflection. It has been the practice sometimes to give the tips a little extra curvature, called "nip," which increases the friction between the leaves. This extra inter-leaf friction was for the purpose of rapidly damping the spring vibrations, thus preventing excessive rebound. It has the one disadvantage, however, of making the springs stiff to small vibrations which has of late been considered undesirable. The recent trend has been to decrease the inter-leaf friction and mount some auxiliary type of damping device, a shock absorber, to prevent the rapid upward acceleration but not to add compressive resistance to the spring. These devices are of many different designs but are basically of two types; mechanical friction and hydraulic friction.

The design of a laminated leaf spring is too complicated to be taken up in detail. It is often the custom merely to specify the length between the eyes, the width of the spring, the number of pounds required to deflect the spring one inch and the load to be carried in a certain position, leaving the rest of the dimensions to be determined by the spring maker. The basic formulae for designing leaf springs will be found in most engineers' handbooks, but the permissible departures therefrom, based upon results obtained by experiment and practice, may best be determined by the specialists engaged in spring manufacture. The flexibility of the springs is indicated by the "rate," that is, the number of pounds required to deflect the spring one inch. The "normal load," which is the portion of the weight of the car and passengers which is carried by the spring, divided by the "rate," gives the number of inches of initial deflection. This initial deflection determines the periodicity of vibration which may be roughly determined by the formula: $V=\sqrt{\frac{35300}{D}}$ when D is the initial deflection in inches.



BY COURTESY OF GENERAL MOTORS CORPORATION

FIG. 24.—PARTIAL SECTION FRONT END OF CHASSIS

It has been found that the rear springs must have a periodicity of vibration below 90 per minute in order to have satisfactory riding characteristics. It is evident that if the front end of the car has the same or a multiple of the same frequency of vibration as the rear end, resonance will exist between the front and rear and the car will "pitch" or "gallop" badly. It is, therefore, necessary to have the periodicity of the front end of some higher frequency other than double that of the rear. Thus it will be understood that the riding quality of a car is determined by the loading characteristics rather than by some particular type of spring. The increased number of miles of improved highways has brought the question of riding quality more and more to the attention of the designers, who have found the use of springs of a greater degree of flexibility plus the addition of some controlling device necessary to meet this demand. Fig 24 shows the front portion of a complete chassis.

Accessories.—The air to the carburettor, fuel and lubricating oil supply of an engine must be kept free from sharp particles of dust and other foreign matter, to prevent excessive wear of the moving parts or the plugging of the oil or fuel lines. To do this petrol filters, oil filters and air cleaners are used. Air cleaners also reduce the amount of carbon deposit in the combustion chamber, as much of this deposit is composed of road dust. Air cleaners are made in the centrifugal, inertia, screen and liquid types. To indicate the operating conditions to the driver, oil pressure gauges, ammeters, petrol gauges and speedometers are mounted on the dash. The four main types of speedometers are air friction, air blower, centrifugal and magnetic, the latter being by far the most common. As automobiles have become more numerous, theft prevention has become a problem of increasing importance. Numerous types of locks operating on the steering gear, transmission, throttle, intake manifold, ignition coil, ignition distributor, breaker or clutch are in use. A lock may operate on two or more parts of a car to give increased protection. The mod-

ern automobile is fitted with many accessories to make it more attractive and convenient. These may include bumpers, windshield wipers, rear view mirrors, radiator ornaments, cigar lighters, vanity cases, ventilators, heaters, etc.

Metals in the Motor Car.—A wide variety of metals is used in the various component parts of the automobile. Members subjected to greatest stress are in the power-transmitting train, such as connecting rods, gears, propeller shafts and rear axle shafts. In some vehicles, it is necessary that some of these members have over 200,000 lb. per sq.in. elastic limit and 250,000 lb. per sq.in. tensile strength. Most of the parts of an automobile made of steel have, as their primary function, resistance to distortion under load and ability to transmit considerable power without failure. Grey cast or malleable iron is used for castings of intricate and complicated shapes. Cast iron is used for cylinder blocks because of its resistance to wear and low friction. Malleable castings are used in certain places where shock is encountered, to insure against abrupt failure.

Copper is used, on account of its high electrical conductivity, in the electrical equipment, including lighting, ignition and starting motor circuits. It is also used for gaskets, which are washers of various shapes and sizes consisting of a soft material such as asbestos sandwiched between metal sheets. Brass and bronze are used as castings or rolled sheets. These metals are used as bearing materials to reduce friction between moving parts. Low unit weight is an important advantage of aluminium. Because of the comparatively high cost, its use is confined in most cars to pistons where its high thermal conductivity and low weight contribute to the efficient performance of the engine. In the more expensive cars, the weight of the engine is reduced by the use of aluminium crankcase and transmission housings. Aluminium alloys are also used for body fittings, and by some manufacturers for radiator shells, on account of their resistance to corrosion.

Nickel is used for the electrodes of the spark-plug. The high melting point, electrical and thermal conductivity, as well as resistance to corrosion, are the properties which cause its selection for this service. It is also plated on radiator shells, lamp rims, etc., as a protective coating and for appearance, and in some cars the radiator shell is made entirely of this metal. Tungsten is used as contact points in the ignition circuit where the spark is timed to synchronize with the position of the piston. The resistance of tungsten to corrosion and to the pitting which results from the electric spark is its principal recommendation. In the high tension magneto (*q.v.*) platinum points are generally used for the contact breaker.

Zinc base alloys are used for die castings for the economical manufacture of small complicated shapes, provided very little strain is applied. Zinc is used as a protective coating on bolts and wheel rims. Cadmium is also used as a protective coating on certain parts. Chromium is plated on surfaces to resist wear, tarnishing and corrosion. It is frequently plated over nickel on such decorative parts as radiator shells and lamp rims. Silver is commonly used to plate head-light reflectors, because of its efficiency in reflecting light and its ability to take a high polish. Occasionally other metals with a lower reflecting efficiency are used because they are less likely to tarnish. Tin base alloys are used for the engine bearings. They provide a surface that permits the crankshaft to turn with a minimum of friction. Lead castings are used for battery plates. Their function is to enter into a reversible chemical reaction which alternately stores and supplies electrical energy for lighting and starting circuits.

PRODUCTION

The development of mass production of automobiles since the beginning of this century, especially since the beginning of the World War, has been remarkable and far-reaching, its influence being felt in almost every other line of manufacturing. This development has been due very largely to necessity, because in the early days of the industry, when 10,000 cars a year was a big output, buildings were not designed to embody any specially helpful feature, nor were they large enough to handle the increased volume under the old methods, where one workman did many operations, and the work moved slowly and at irregular intervals until it was finished. Among the pioneer companies which have been forced by the growth of their business to construct additional buildings and reorganize old ones the principle of progressive production has been carried out to a fine degree. These buildings are laid out so that all parts and sub-assemblies move forward to the main or final assembly line with the least amount of duplicated travel possible. The phenomenal growth of the industry has presented the problems of inventory and material handling. If material on hand and in process were handled to-day by the old methods, the inventory would be prohibitive and the production slowed down beyond belief.

The development of material handling within the plant has undergone many improvements. The following items show the evolution of these methods: (1) four-wheel truck; (2) hand-lift truck, with movable rack; (3) electric or gas truck, with movable rack or trailer; (4) mechanical and gravity conveyor. While all of these methods are still in use for some phases of material handling, the last is being more and more used wherever the situation warrants. The use of the improved methods has relieved congestion, speeded up production and reduced inventory. The use of motor trucks for transporting materials between buildings is being superseded in many cases by conveyors. Distance alone is no barrier, for in certain cases conveyors a mile long are in use. Some companies operate their own fleets of motor trucks on regular schedule from supplier to their own plant, in preference to relying on the railroads. In this connection it is becoming common practice to provide large loading docks to facilitate the loading and unloading of trucks, just as it is customary to provide loading platforms for railway trucks. (*See* CONVEYORS IN MASS PRODUCTION.) In many cases where the manufacturer is a quantity producer, he makes all the various "units" going into the whole assembly, except those which are highly specialized, requiring an enormous amount of floor space and capital as well, such as electrical equipment or tires. From this, then, it will be seen that the automobile manufacturer makes grey iron, aluminium, brass, and in some cases malleable castings, die castings, forgings, sheet-metal stampings and glass; and does all kinds of plating, enamelling, painting and machining and assembling. In addition, he has tool, die and pattern shops for making and maintaining tool equipment.

It has become customary among many of the larger companies to bring out about every 12 months what are known as new models. These are either an entirely new series or the old series changed to embody the latest improvements and refinements. The development of the new line starts months before it is scheduled for manufacture. Experimental cars are built and tested through thousands of miles and as far as possible under all of the conditions to be experienced by the future owner. Each series frequently consists of as many as 15 or 20 models differing from each other in chassis or power plant or body. Each model may be built with a choice of several styles of wheels and many different body colours, all of which further complicate the problem of quantity production at low cost.

When the series is finally approved, the problem of the big producer is how to finish the run on the old series and begin on the new with the least possible break or loss of time in between. This requires consideration of all the following subjects: Bill of material or list of every part in each model; designing and making of new tools, dies, patterns, etc.; ordering and installation of new or special machines; relocation of old machines and equipment, if necessary to facilitate production of the new parts; routing of each part by operations; running ahead on parts to be discarded to give opportunity to try out new equipment; (*a*) time required for each operation and for moving from department to department or building to building; (*b*) number of cars scheduled per day; (*c*) number of days float or quantity needed to keep the parts moving steadily from raw state to finished car; (*d*) amount required ahead of primary operation as a protection against unforeseen delays in transportation; (*e*) time required for supplier to make shipment; (*f*) time required in transit. Then: Time—*a* plus *e* plus *f* equals number of days that material must be ordered

in advance of shipment of automobile. Material—*b* times *c*, plus *d*, equals amount of material required in the plant at all times, *c* only varying inversely with a change of capacity.

To start a series in production on scheduled time and to keep production running smoothly requires an experienced organization, the skeleton of which follows:

Management	Engineering	Development
		Testing
	Purchasing	Buyers
		Traffic
		Stores
	Manufacturing	Production
		Efficiency
		Factory

While refinements and improvements have been steadily incorporated for years in all parts of the car, this development has led to many economies in methods, especially during the last ten years.

Processes Characteristic of Modern Practice. *Heat Treating.*—Twenty years ago little was known about this subject, whereas to-day steels are treated for strength and wearing properties in a highly scientific manner, thus providing against breakdowns and ensuring a longer life for the car. There has been a great change from the old "batch" type of furnace to the present-day continuous furnace, at one end of which the operator loads the constantly moving conveyor with forgings. Forgings travel through the annealing furnace, through a quench, then through a drawing furnace without any labour. This principle is applied to pre-heating furnaces in the forge shop, where billets are loaded at one end and travel to the outlet, gradually acquiring the forging heat. In these cases time, labour and fuel are saved.

Plating.—The first automobiles were equipped with brass head-lamps. Along with the development of the electric lighting system for automobiles, nickel plating came into use on lamps and other outside trimmings. Later, radiators called for nickel plating, which necessitated enlarging of this department in the factory and putting it on a progressive basis. Recently, chromium for plating automobile parts such as radiators and lamps has been used by some manufacturers. This plating is not as easily scratched as nickel, and will not rust or tarnish. The plating of rims, usually galvanizing over a copper strip, has not changed much except in method of handling the work. Rims can now come from the forming rolls and sizing machines to conveyors which conduct them through tanks to inspection without manual labour.

Painting.—Painting as applied to automobile bodies has undergone a great many changes. At the beginning of the century bodies were made entirely of wood, and were painted by hand with a brush, pushed around on trucks by hand, and stood up on end to dry after each coat was applied. A good paint job required approximately 24 major operations and 14 drying periods ranging from six to 24 hours, the whole taking about 21 days from start to finish. With the introduction of steel body panels, drying ovens could be used which speeded up the time of drying. With the flow system of applying varnish together with conveyors, more time and much labour were saved. Within the last few years the use of the quick-drying cellulose finishes and spray guns has still further speeded up the work and reduced the labour cost, until bodies can be finish-painted in regular course in four days, or in 48 hours if necessary. Aside from the saving in labour and floor space required for storage, the saving in inventory has been tremendous. Enamelling of wings, or fenders, and other sheet-metal parts presents another advancement even in the last few years. For many years these parts were dipped by hand in the bath, hung up to drain, transferred to a truck and pushed into a drying oven, which had to be brought up to the proper heat after being loaded. After baking, the oven had to be opened and the parts cooled off before preparing for the next coat. To-day the preparation of the parts is about the same, but they are now hung on a constantly moving conveyor, run alternately through several baths and baking ovens, inspected and conveyed direct to the car assembly line. Here again is a big saving in labour, material, fuel, floor space and inventory.

Foundries.—Only in comparatively recent years have foundries been operated on a strictly progressive basis, and the transition from hand labour to machine and conveyor has kept pace with improved methods in other branches. Machines are now used for ramming cores and moulds; sand is mixed and conveyed to moulding machines mechanically; moulds are made, cores set, castings poured, cooled and shaken out while in motion. Cupolas are charged mechanically. Here again is a great saving.

Machine Shops.—Modern machines have reduced labour, speeded up production and reduced inventory. Not only have the modern machines made closer limits possible with the resultant reduction in scrap losses, but in some cases have made it possible to incorporate improvements and refinements otherwise impossible on an economical quantity production basis. Some machines typical from a production standpoint are multiple drills, for drilling 100 holes in all sides of a casting such as a crankcase at one time, and the revolving planes on which castings are loaded and unloaded while in motion. Centreless grinders are used considerably to speed up the grinding of certain parts. Special machines are used to balance crankshafts, fly-wheels and other rotating parts.

Stamping Plant.—With the change from all-wood bodies to framed bodies panelled in sheet-metal, the stamping plants took on a big increase in work. Many parts formerly made of forgings or malleable castings are now made of stampings, reducing cost and weight. (*See* Motor Car Body.)

Assembling.—It is in all branches of assembling that the progress made in the industry is most striking. Whether it be a motor, axle, transmission or entire car, the assembling is done on a steadily moving conveyor, all parts being fed to this conveyor at the exact place and time needed. The routing and scheduling of the individual parts and sub-assemblies through the various plants or departments to arrive at the final assembly line on time and at the required rate is a nice problem in synchronization, as some of the primary operations must start weeks ahead.

Service.—Provision of repair parts for the owner has been given a great deal of attention for years, not only as to requirements but as to interchangeability. It is the aim of every manufacturer to have a part on hand when the owner wants it. The rapidly increasing number of cars in use and the constant changing of models has complicated the matter, but for those who have studied the question for years each year gives better data as to the life of various parts of the car. In this way the manufacturer can estimate closely what parts will be required for replacements, and plan production accordingly.

The Modern Road Testing.—In order to determine successfully the way in which an automobile will function in the hands of the average owner, motor car manufacturers have made a practice of conducting tests over a wide variety of road conditions, and recording data as accurately as possible on the performance over thousands of miles. Such tests must be carried on, as it is not possible to duplicate exactly tremendously varying road conditions, even with the most elaborate laboratory equipment. It is not possible in a laboratory to reproduce the violent stresses to which a car is subjected in driving over frozen, rutted roads. Road testing naturally follows the detailed development work of the component parts of an automobile and provides a means of checking the final design to determine the characteristics of comfort, performance, economy, reliability and durability. When such tests are conducted on the public highways, many variables must be taken into consideration, such as weather, condition of roads, traffic and legal regulations. As a result, delays frequently occur, and often the tests are a source of danger to other users of the highways. All of these factors have some effect upon the accuracy of the tests and the speed with which the information may be obtained. Consequently, manufacturers have utilized such facilities as may be available where carefully controlled tests may be made.

In past years racing provided a very good means for such tests, but in more recent times, due to arbitrary rules set up by the governing organizations for racing, it is hardly feasible from the economic point of view for manufacturers to take this means for

checking the performance of their cars. Several American motor car companies, in order to provide standardized conditions for tests, have installed private testing grounds containing a wide variety of roads where many conditions can be maintained constant and so designed that motor cars may be operated day and night at all times of the year. Such a road system includes highways where sustained high speed may be maintained with safety, concrete hills with accurately laid gradients, level stretches to insure elimination of error in critical engineering tests,—in fact, a duplicate of nearly every type of road found among the public highways. Other manufacturers have utilized only the high-speed track. One company in Italy has gone so far as to incorporate this track on the roof of its factory building. Under such standardized conditions, cars may be tested and the results compared from day to day and year to year with reasonable accuracy.

The private testing ground offers many advantages over the public highways, in that traffic conditions can be controlled definitely and the information obtained on the tests is more quickly available to the designers. Even though the test car travels 1,000 m. or more a day, in the event of failure of any part, it is still only a few minutes away from the shop and the engineer. Again, such a testing ground as a part of the automobile manufacturer's facilities permits the establishment of definite standards of performance, comfort, economy, reliability, etc. It permits the manufacturer to operate his experimental design simultaneously and under the same conditions with any other cars with which he wishes to compare for speed, acceleration, braking, riding qualities, or anything else of importance to the customer. Thus the designer is able to set up a continually improving set of specifications based upon the hitherto intangible operating differences between various cars.

Research in the Automobile Industry.—In the early years there were comparatively few efforts at systematized research, although those few efforts which were carried on by early automobile engineers quite merited the title of research. Conditions have changed, however. Developments garnered from every day necessities and simple observations will not answer now. The world has become quite technical and complex—so much so that the automobile industry cannot hope to maintain its position without the assistance that science can render. The acquisition, development and application of new knowledge is necessary for continuous growth. Groups of trained and well-educated men are brought together, properly housed and furnished with adequate equipment, and are set to work on the major problems of an industry. Men of initiative are sought, and they work tirelessly in a definite place on a single problem, until success comes. (*See* RESEARCH, INDUSTRIAL.)

Investigations leading to the discovery of fundamental facts come under the jurisdiction of the research laboratory. Research points the way to new products; it steadily improves the existing product; research makes money and saves money for the automobile manufacturer. Many research laboratories, proving grounds, etc., have sprung up in the automobile industry—some of them employing 300 to 400 highly trained specialists; chemists, electrical and metallurgical engineers, mechanical experts dealing with engines and chassis design, strength of materials, thermodynamic principles, new metallurgical developments, etc. Other research organizations exist also for the intensive study of marketing, sales and service problems, for research is not confined to materials and mechanical questions alone. (C. F. KE.)

EUROPE

Up to 1900 the development of the motor car was mainly due to continental engineers. After the abolition of legislative restrictions in Great Britain in 1896, many British engineers, scientists and inventors realized the industrial possibilites of the motor car, and the names of Lanchester, Royce, Napier, Thornycroft, Dugald Clerk and many others became famous during this period. Modern European cars generally conform to a certain arrangement of component parts dictated by experience. The radiator is mounted at the front end of the frame, with the engine immediately behind it. The engine is covered by the bonnet which merges into the body, this occupying practically the whole length of the frame behind the bonnet. At the rear of the engine is a clutch connecting the engine with a gear-box from which the driving effort of the engine is transmitted to the rear axle through universally jointed shafts. Two axles are used, front and rear, the former allowing for the angular movement of the front wheels necessary for steering, the latter being so constructed that the rear wheels can revolve at different speeds when rounding bends in the road. Brakes are fitted to each wheel. The driver, in his seat, sees in front of him the steering wheel with levers mounted thereon to control the ignition and the throttle, and an instrument board which carries the switch, speedometer, clock and other accessories. At his side are the change speed and hand brake levers; at his feet are the accelerator pedal which enables him to vary the speed of the car by controlling the throttle opening, the clutch pedal which disconnects the engine from the transmission, and the brake pedal which applies the brakes to all four wheels. In bare outline such is the disposition of the units of the modern car.

Body-work and Equipment.—Few points are more carefully studied in modern motor car design than the lines, curves and colouring of the body as viewed from outside, and the disposition of the seats, internal lighting arrangements, colour and quality of the fabric or leather used in upholstering. The radiator and bonnet have always been characteristic features of various makes, and these are made to conform to artistic requirements without losing their essential character. The necessary large difference in width between the body and the bonnet necessitates a merging of these two by the scuttle, which is between the rear end of the bonnet and the wind-screen. This encloses the pedals and other controls. In small cars it often carries the petrol tank, which is, in larger cars, carried at the rear end of the frame, the petrol being delivered to the engine by a suction device. Body-work is constructed in a variety of types and with many artistic variations, the style and quality depending largely upon the price at which a car is sold. There is a distinct line of difference between cars which are intended to be owner-driven and those built to be chauffeur-driven.

For bodies constructed in large quantities steel pressings are largely employed, but a wooden framework panelled with aluminium is also used to a considerable extent. Of quite a different character is the Weymann body in which the wooden frame is so jointed as to be to some extent flexible, and is covered with padded fabric. This and other similar types have been evolved to safeguard the body from racking effects caused by twisting of the chassis frame on rough roads. (*See* MOTOR CAR BODY.)

Popular Types of European Car.—Owing partly to systems of taxation based on horse-power rating formulae which, in turn, depend upon the cylinder dimensions of the engine, European designers have tended to concentrate upon the use of small engines made to develop considerable power by various expedients, so that it is quite common for a European car to develop two and a half to three times its rated power. The size of the engine is therefore better expressed by stating its capacity; *i.e.*, the volume swept by the pistons, which can be given in cubic centimetres or litres. In 1928 the most popular type of European car was one equipped with a four-cylinder engine rated at about 12 h.p. with a capacity of between 1,500 and 2,000 cubic centimetres. Another important four-cylinder type is the baby car rated at about 8 horse-power. In the case of the larger cars manufacturers have turned their attention more and more to six-cylinder and eight-cylinder engines with a view to obtaining greater smoothness and flexibility; a type which has grown in importance is the six-cylinder car of moderate price rated at from 14 h.p. to 20 h.p., with a capacity of from $1\frac{1}{2}$ to $2\frac{1}{2}$ litres. Apart from these varieties there is the large and powerful high-priced car, with a rating of 40 h.p. or more, and with 8 or even 12 cylinders, and the sports model in which performance ranks first in importance, followed by appearance, and with comfort as a poor third.

The following are typical brief specifications of the medium-powered six-cylinder car, baby four-cylinder car and the large

high-priced car, the examples taken being the 14 to 45 h.p. Talbot, the 7 h.p. Austin and the Daimler "double-six."

Medium-powered Six-cylinder Car.—Engine: bore 61 mm., stroke 95 mm., capacity 1,666 cu.cm., rating 13·8 h.p. overhead valves, push-rod operated. Transmission: single-disc clutch, four-forward speed gear-box, enclosed propellor shaft, spiral-bevel final drive. Gear ratios (forward) 23·19, 13·45, 9·66 and 5·875 to 1 (reverse), 17·39 to 1. Brakes: pedal-operated four-wheel brakes; hand lever controls rear brakes; suspension: front, semi-elliptic springs; rear, quarter-elliptic springs; four shock absorbers; petrol system: 14 gal. rear tank, feeding through vacuum tank or dash; dimensions: wheel-base 10 ft., track 4 ft., 7½ inch.

Diminutive Four-cylinder Car.—Engine: bore 56 mm., stroke 76 mm.; capacity 747·5 cu.cm.; rating 7·8 h.p.; side by side valves; transmission: single-plate clutch, three-forward speed gear-box, enclosed propellor shaft, spiral-bevel final drive; gear ratios (forward) 16·9 and 4·9 to 1 (reverse), 21 to 1; brakes: hand-operated front brakes, foot-operated rear brakes; suspension: front-transverse semi-elliptic spring; rear two-quarter elliptic springs; frictional shock absorbers combined with radius rods; petrol system: 4 gal. scuttle tank, feeding by gravity; dimensions: wheel-base 6 ft. 3 in.; track 3 ft. 4 inch.

Large Twelve-cylinder Car.—Engine: bore 81·5 mm.; stroke 114 mm.; capacity 7,135 cu.cm., rating 49·4 h.p.; double-sleeve valves; transmission: plate clutch, four-forward speed gear-box, open propeller shaft, worm-and-wheel final drive; gear ratios (forward) 15·8, 10·15, 7·6 and 4·86 to 1; reverse 15·8 to 1; brakes: pedal-operated four-wheel brakes; hand lever controls transmission brake; suspension: four semi-elliptic springs and shock absorbers; petrol system: 24 gal. rear tank feeding through vacuum tank on dash; dimensions: wheel-base 13 ft. 7 in.; track 5 feet.

Racing Cars.—Many sporting events take place annually for which a number of prominent European manufacturers build highly specialized types of car. These differ markedly from the ordinary kind of chassis sold to the public, but in their design a great deal of data is obtained which is of considerable value in improving the performance of the private car. In a racing engine everything except reliability is sacrificed to power output, and very often a supercharger is employed to pump the mixture of petrol and air into the cylinders. Needless to say, the chassis is stripped of every unnecessary component, and is also specially constructed with a view to making the car as light as possible. Most record-breaking attempts and races are run under regulations which severely curtail the size of the engine permissible, so that small 1,500 cu.cm. racing cars have been developed capable of 150 m. per hour. Distinct from these is the 200 m. per hour type of record-breaking car, of large size and weight, which is usually propelled by one or more aero-engines.

Methods of Car Production.—In Great Britain and on the Continent, there are a few manufacturing concerns employing quantity-production methods similar to those used in America, although on a smaller scale, such as Morris, Austin, Citroën, Renault and Fiat. Additionally, there are very many makers producing cars in strictly limited numbers who stimulate the development and adoption of new ideas; a small output enables them to change designs more readily than the larger concerns and so to keep ahead in technical improvements. Their prosperity depends upon the fact that there is always a certain number of European buyers wanting a car differing from the mass-produced types. Some of these smaller firms specialize in racing and sports cars, while others build large, powerful and expensive chassis. In a typical British quantity-production factory arranged to turn out approximately 1,000 cars per week, the chassis, or mechanical part, is assembled upon a slowly moving conveyor, frames being placed on the track at one end and gradually fitted with springs, axles, power units, etc., as they move along. Running at right-angles to this assembly line are a number of sub-assembly lines, each feeding a component to the appropriate point. On each sub-assembly line will be grouped the necessary plant and fitters for the making and building of the component concerned. The end of the chassis assembly line is arranged to meet the terminus of a similar line on which the bodies are built up, each completed body being then lifted with tackle and dropped on to a chassis to which it is bolted down. In the making of both the chassis and body of a car produced in quantities, standardization is essential and a close control of dimensions must be ensured both by careful planning of the machine tools and fixtures and by elaborate systems of inspection on the sub-assembly lines. The complete car is given a short-road test and engines are run-in and tested independently before being fitted to the chassis. Similar methods are in vogue at the factories of Citroën and Fiat on the Continent.

During 1926 the principal European car-producing countries built the following numbers of cars:—Great Britain, 158,699; France, 150,000 (approximate figure); Germany, 37,000; Italy, 50,000 (approximate figure); Belgium, 5,000; Czechoslovakia, 6,000; Austria, 3,960. (*See* also MOTOR VEHICLES, COMMERCIAL; MOTOR CYCLES; MOTORING; MOTOR VEHICLE INSURANCE; INTERNAL COMBUSTION ENGINE and the section of this article: *Motor Car Body Design.*)

MOTOR CAR BODY DESIGN

This subject, which deals with aesthetic considerations in relation to motor car body design, is treated comprehensively below and also under a following section, *United States.*

DESIGN

In automobile design, the artistic or aesthetic side of the designer's craft is subservient, *i.e.,* there is no true place for decorative art as such in the modern automobile. The body designer can only exercise his powers within well-defined limits; he is bound by certain factors as to proportions, measurements, etc., with which few liberties can be taken. The designer's province as an artist is to give character to the ensemble and by well-chosen lines and treatment to suggest such attributes as power, comfort and speed, and to emphasize and not to destroy the feeling of structural unity.

Early Errors.—Automobile designers have much for which to thank the earlier carriage builders, without whose example and traditions they would have been unable to make such rapid progress. Nevertheless, they erred in the past in copying features of horse-drawn vehicles, instead of going deeper into the origin of such features and forming a true appreciation of the new problems which the change in the manner of locomotion involved.

In the single brougham, or coupé, we require firstly a seat for two, carried on an axle by a pair of springs. The axle position is determined by the need for bringing the springs beneath the seat part of the vehicle and not under the vehicle; convenience of access demands this, the brougham is not a vehicle for the young and athletic and the access is one of the governing factors in design. Next we have to assign a position for the front axle; this, on the established system of horse-drawn vehicles, requires to be mounted on a perch bolt and turn-table with room to swing well over on the lock; thus, the position of the perch bolt, or pivot pin, in front of the body of the vehicle is determined. Also, in order not to require too high an arch over the wheel when on the lock, the front wheel is made of smaller diameter than the rear wheel, where no such conditions apply. Now, having drawn the position of the turn-table and the arch, we have ready-made the position for the driving seat; the footboard and dashboard follow

as a necessary sequence. The vehicle is to be a closed vehicle which determines approximately the height and size of the body. The back panel, of course, is sloped to follow the general position of the passenger's back and the squab. The door position admits of no alternative. Now the ingenuity of the engineer or constructor is needed. The vehicle has very little strength; if loaded it would collapse. To give the necessary strength a frame reinforced by steel members is provided under the door and continued from arch to dumb iron. It is here that the designer's art comes into play. Apart from his knowledge of construction, his rôle is to give unity and character to the design. There are no redundant lines or ornaments, the treatment is severe and is simplicity itself, but such simplicity was only achieved after centuries of experience. There is one point in particular which calls for attention, viz., the bringing forward of the line of the front door post to form, as it were, a "cusp" and so disguise what otherwise is liable to be unsightly, the junction of the visible part of the frame with the body proper.

When the automobile designer first endeavoured to design a coupé, instead of analyzing the origin of the horse-drawn coupé or brougham and learning its lesson, viz., that no lines or features of design which are foreign to the necessities of the case can live, he took the side of the horse-drawn coupé and, as it were, plastered it on to his chassis, or body drawing, just as we see sham columns plastered on to the walls of buildings in certain examples of bad architecture. The problem of the designer of that period was in not knowing what to do with his door post line when he had finished with it. The result of experience has since decided that door post lines and other vertical lines require to be eliminated or subordinated entirely to the lines denoting horizontal structure. This is one of the most important principles that has been established in the art of automobile body design: the dominance of the horizontal line. After the event it is easy to understand how inevitable this should be. The whole character of speed, which is the "breath of life" of the automobile, is consistent with the horizontal line and the horizontal partitioning of the design. Vertical lines and vertical sub-divisions are lost and meaningless in rapid motion; they belong to and are only consistent with things stationary or slow moving. The horizontal line in itself suggests speed. The arrow, the javelin,—length in the direction of motion—give instantly the suggestion of speed.

Returning again to the horse-drawn vehicle, here the need for weather protection, which is imperative in the automobile, was far less pressing, and in the introduction of doors in the early automobile (where such would not have existed in an equivalent horse-drawn vehicle) judgment was warped by traditions of the old carriage builder's idea of elegance in lightness of line and design. This resulted in these doors being at first made low with pretty curves and decorative mouldings. Instead of the automobile designer boldly proceeding on the firm basis of utility and then allowing his artistic sense to harmonize his lines with his purpose, he put the cart before the horse and endeavoured to allow what he thought was artistic feeling to interfere with his freedom of choice. Early attempts to establish a horizontal waist line were hampered by the dread of giving a heavy or clumsy appearance. This was due to regarding the design as static, something suitable to stand in a glass case, and not as a vehicle travelling along the road at 40 or more miles an hour. The straight and uncompromising waist line of a modern car would have been reached many years earlier if nobody had worried about the appearance of a car at all, and, paradoxical as it may seem, the result would have been the attainment of beauty far sooner.

Structural Unity.—One of the results of modern design has been, as already stated, to present the car to the eye as a structural unit. The blending of the body and bonnet characteristic of the modern car may be cited as an example of this tendency. There is an appearance of strength and power about a machine whose lines suggest structural unity that does not exist otherwise and cannot otherwise be suggested to the mind.

Before a considered judgment can be formed on the score of artistic merit, whatever the subject may be, the artistic sense requires education; there is no realm in which preconceived ideas are more prone to be the subject of prejudice than that of the arts. Some go as far as to assert that merit in art is merely a matter of taste. It is not altogether easy to combat such a statement; there is, however, one sound reply, viz., the general tendency of the evolution of the individual. Among those who take an interest in any art, progress in taste goes with experience. Thus we make the public—the interested public—the final and ultimate judge. It is the general direction in which the public appreciation tends, not the verdict of the majority at any moment nor the pendulous swing of fashion, that decides the reality and soundness of the advance made in all that pertains to appearance and in the art of the designer which contributes to same.

Decoration.—There are certain factors that enter into the design and appearance of the automobile which require separate consideration and discussion. Some cars exhibit a lavish display of nickel plate work, revealing a practice that is almost universally condemned. Nevertheless, tradition permits us to brighten up the otherwise dull appearance by means of showy lamps, and a conspicuous radiator-frame and crown. A car with no bright metal work rarely satisfies the eye, and, although possibly this may not always be so, it is probably justified. The hunger for some such decorative embellishment may be a survival of the fact that the well turned out horse-vehicle, the glossy coated chestnuts or bays, and the well-polished harness-fittings and lamps must have their counterpart in the power-driven vehicle. The justification or condemnation of this view, time alone will determine, but there is one fact that quite early impressed itself, viz., that any accessories, such as lamps, horns, etc., must either be made quite inconspicuous or must be developed as a definitely striking feature or ornament.

Colour.—Another much debated question is that of body colours. Comparatively few appreciate the reasons for avoiding brilliant or violent colours. We know that in the days of the horse-drawn vehicle such colours were "bad form," and with few exceptions, such as the coach yellow used on stage coaches and vehicles of a sporting character, any well turned out equipage was finished in a dark colour, such as a deep lake, a dark blue or green, or even black. The underlying factor, and the principal reason for this exclusive use of non-committal colours, was the need for avoiding a clash with ladies' dresses, and perhaps in the 18th century with the colours worn by men also. Another factor, however, which cannot be ignored is of visibility. In entering a thoroughfare out of a side road, for example, especially in the dusk, the driver has to concentrate his main attention on approaching traffic, and it has been the experience of many drivers that in doing so he has failed to see a car approaching in the other direction, *i.e.*, in the line of traffic which he is about to join. Especially does this apply when the colour is of a uniformly sombre hue; this question of visibility arises in other road experiences. Consequently there is a demand for tints and colours which, while not liable to clash with the costume colours of the passengers, are sufficiently conspicuous to give good visibility. Such colours as the various shades of grey, light russet, biscuit-colour, pale coach yellow, etc., are coming to be accepted as consistent with good form, even in automobiles of the most exclusive class. (F. W. LA.)

UNITED STATES

The first automobile bodies were open bodies, consisting of a front and rear seat, each seat being designed to accommodate two persons, and were upholstered in leather. The rear seat was generally entered through a small door in the middle of the back. In 1902, side rear doors were added, displacing the middle back door, but there were not as yet doors for the front compartment. Such doors did not come into use until 1910–12. It was not until 1910 that bodies were equipped with windshields as standard equipment, although these could be purchased as special equipment. The first windshields were made with wood frames. Cars with tops as standard equipment had appeared in 1907–08. These were merely carriage tops, the folding top, which could be lowered or raised with comparative rapidity, coming into use in 1910.

Until about 1910, very few cars were equipped with closed bodies; the open body—touring car or roadster—represented practically the entire automobile production. Makers of closed bodies

still clung to the traditions of the horse-and-carriage days; bodies were built to individual patterns and almost entirely by hand. In 1910, an important body manufacturer obtained an order from a quality car manufacturer for 500 closed bodies. The body manufacturer had begun to apply chassis methods of standardization and volume production to the manufacture of both open and closed bodies, and had thus brought about more economical body manufacture. The entire automobile industry watched the experiment with close interest. Many doubted whether closed bodies so produced would be successful. Many more doubted if sufficient demand existed for 500 closed cars. However, the closed cars were successful from the owner's viewpoint and from that of the manufacturer, who the next year increased his order. These closed cars, driven not only in the large cities of America but in many of the smaller centres, proved the practicability of the closed automobile. They marked the definite beginning of a turning to the closed car.

THE CLOSED CAR

The progress of the closed car in the motor world, in proportion to the number of open cars produced, was at first, however, very slow. This is explained by the fact that the cost of the closed car was, in earlier years, far in excess of the cost of the open car, for two main reasons: (1) the closed cars were produced in small quantities; (2) the material and labour for the closed car were more expensive. The art of building closed cars developed slowly; costs were reduced only gradually. Furthermore, car manufacturers as a whole did not encourage the closed car sale. They looked upon the closed car as an impediment to production and a potential cause of complaint. The first closed cars were flimsy structures which rattled and creaked even when a car was travelling over the smoothest city pavements, and were decidedly impracticable on unpaved roads. For many years, in fact, the closed car was looked upon as a rich man's toy, the public referring to them as "show-cases." They were seldom driven outside the city and very few were found even in the largest centres.

One of the chief reasons for the lack of practical service in the closed automobile bodies of earlier years was the fact that they were inadequately engineered. The most important defect was insufficient bracing. Gradually, however, the internal design of closed bodies was improved. Body engineers provided far greater strength and rigidity without increasing the weight. Even as late as 1917, however, open bodies constituted the bulk of motor car body production, but at this time observers of the trend of the automotive industry began to predict that the closed car would eventually come into general use. In compactness and in strength, the closed bodies of this period left much to be desired, although improvements were being made with notable rapidity. By 1920, fundamental structure had been vastly improved, but the closed car was still, in some degrees, "a show-case on wheels." The roof was high and the contours lacked gracefulness. Efforts were being successfully made to lower the closed car. As this was accomplished, the lines of the closed car became more sweeping, more harmonious. The body, instead of appearing to be mounted on the chassis, seemed to become integral with the chassis. Windows became oblong rather than square and all lines, including the fender lines, brought the car, apparently even more than actually, closer to the ground. One of the chief difficulties which was overcome in lowering the motor car was the rear axle.

With the improvements and decreased cost of closed cars, they came into wider use. The National Automobile Chamber of Commerce of the United States supplies the following figures showing the percentage of closed cars manufactured, as compared with total motor car production, by its members from 1922 to 1927, inclusive, these figures including all excepting the Ford Motor Car company: 1922, 37·2; 1923, 36·8; 1924, 47·6; 1925, 69; 1926, 82·6; 1927, 85·5. Closed bodies are built so strongly to-day that a car can be driven over the most uneven roads consistently without developing weaknesses or unpleasant noises, provided ordinary servicing is not disregarded. It is largely because of the economies achieved in motor car closed body production that the automobile is a relatively great monetary value. The cost of closed car body manufacture has continuously been decreased and the public has benefited from these economies.

Planning a Body.—Changes are necessary in body lines, in hardware, in style of upholstery, to meet the constantly shifting taste of the public. The public fancy is caught, perhaps, by some change in the motor car lines. A general trend in body and chassis manufacturing is the result. The public is always demanding that which is new and different. Designers and engineers are constantly working to keep ahead of that demand. Before an automobile is ready for production, several steps are necessary. The first of these is transferring, from the mind of the designer to a blackboard, a full size picture of the car. Throughout many previous months he has kept in mind trends in public taste and new chassis developments which may require changes in the body. He has discussed with many executives the new body to be produced. Some of these executives are representative of the public, in that they translate to the designer the opinions of dealers who have, in turn, arrived at these opinions through many conversations with their salesmen and with the public. He also discusses the new body and its requirements with men who know body production—who advise him upon the practicability of the changes.

In designing a body, the designer must observe a great many details. He must always leave a certain number of inches between the seats and the roof for head room. He must allow a certain amount of leg room for front seat and rear seat passengers. The seats, because of the cushions, must be a certain minimum depth, width and length. The doors also must have fixed measurements from which he cannot depart. Comfort and convenience of the eventual owners of the new car require that he conform to these measurements with undeviating exactitude. It is the employment of these fixed measurements in such a way as to create a pleasing, harmonious, beautifully proportioned body, which constitutes one of the chief problems of the master designer. In most instances, of course, his work is based upon the body designs of the year before—for automobile manufacturers generally adhere to the policy of gradual, rather than rapid and radical change.

After the car is drawn on the blackboard, a wooden frame of the new model is set up. This is constructed with painstaking attention to the precise measurements of the drawn model. The framework is then filled out with modellers' clay—the same kind of clay which sculptors use in the modelling of statues. Just as the clay model of the sculptor is later reproduced by workmen in marble or in brass, so the clay model of the new body is to be reproduced in wood and steel by the thousands of craftsmen with machinery which permits quantity production. The clay model is created with the utmost care. A few necessary mechanical parts are employed, such as steering wheel and post, springs and traction wheels, lights and upholstery, but all else in wood and clay. This model is precise in its measurements. It is, to the eye, the complete body itself, with interior lights, hardware and all other fitments installed. After the clay has dried the entire model is painted. It reveals exactly how the new body will look. Expert designers view it with scrutinizing eyes, considering and weighing every detail in an effort to improve it, if possible.

The new body is then created from the engineering viewpoint. It is yet but a model—it must be worked out with respect to stresses and strains, so that it may withstand the daily service required throughout the long life of the car. Furthermore, it must be engineered with full consideration for practical production and every detail of its construction specified—dimensions, materials, etc.

Bracing.—One of the structural body details which must be worked out with painstaking care is the bracing of the different parts of the body. Quality bodies have a heavy iron brace between the front pillar and the top cross-bar; also a machine bolt from the top rail to the pillar, which is a double strength unit to prevent the body from becoming loose and squeaking at this point. Between the front pillar and the dash, where three heavy braces are employed on each side, the body is bolted down to the frame in front, directly back of the motor. Each upright pillar is heavily braced at the bottom also, to insure rigidity. Furthermore, steel plates, set in with wood screws, are installed on the wheel housings.

STEPS IN THE DESIGN AND CONSTRUCTION OF MODERN MOTOR CAR BODIES

1. Motor car design traced on blackboard, scale, or full size
2. Craftsmen building up wood-and-plaster model of closed car tonneau
3. Modellers' clay being applied to the framework of an automobile body model
4. Smoothing the surface of a body model to obtain the exact form of the car
5. Painting the waterproof top of a cabriolet or collapsible top model
6. View of front framework showing windshield and dashboard frame, of wood and steel construction, with slatted top support. View shows the method of attaching upright members of frame to the chassis
7. Completed framework of automobile body showing the wooden outlines or frames and the metal braces joining them. Side window frames in rear seat have been attached
8. Side frame of two-door sedan stamped from one piece of sheet steel
9. Pressed steel parts which fit into and around the framework shown in fig. 7. These include the outlines of windows, doors, panels and braces of the closed car body. The present tendency is toward the use of large pieces of sheet metal for this purpose, to minimize the use of rivets and bolts
10. Overhead view of assembled all-steel body "in-white" before the top, upholstery or paint has been applied
11. Cowl, dashboard and windshield framework of pressed steel. The box or inside space of the cowl contains the instruments and controls for regulating the electrical and oiling systems and the mileage meter and other devices

These plates are the anchors for the fenders.

MASS PRODUCTION OF BODIES

In America the concentration of automobile production in a few factories soon eliminated the small workshops scattered throughout the country and resulted in the development of large body-building units either within the plant of the chassis manufacturer or nearby. Piece by piece, the wooden side panels were replaced by steel or aluminum panels in order to secure better and more durable painting, until finally the entire body was covered by pieces of sheet steel. About 1912 this sheet steel was first drawn into large units. These parts were attached to an inner wood frame and were simply a skin superimposed on the body itself to receive the finishing coats. Many manufacturers still use this outer steel shell over an inner wooden frame.

Steel Body.—About 1915 what is known as the "steel body" was developed. In this design the same outer shell was flanged inwardly at the top and bottom edges and around the door openings and was reinforced on the inside by certain metal members riveted or welded to the outer shell. The wooden posts, sills and braces were omitted. These two types of construction were used in the manufacture of what are known as open or touring car bodies, the solid framework extending up about 10 or 12 in., above the level of the seats. In each case, the body was a distinct member from the chassis, having its floor integral with the sides, and fastened to the chassis frame by means of bolts. Up until about 1920 a very great proportion of automobiles carried such a body. Protection from the weather was by means of fabric tops which were, in most cases, collapsible and by means of removable side curtains.

In the years immediately after the World War, there came a demand for greater comfort on the part of the buyer of moderate means and there were developed closed types of bodies which could be manufactured by the American method of production at reasonable costs. Within the last few years this closed type of body has almost entirely superseded the open type. The demand for very great quantities of bodies at moderate cost has necessitated the development of ingenious methods of manufacture to reduce the cost. (*See* MASS PRODUCTION.)

In the case of the wood bodies, this reduction of cost has been brought about by cutting the framing to dimension stock where the timber is grown, building the bodies by progressive manufacture; by having each operation done on an individual tool by an especially skilled operator; with the assembling, fitting, upholstering and painting on conveyor lines as the body is moved by the successive operators. (*See* CONVEYORS IN MASS PRODUCTION.) This need for reduced costs and weight and the elimination of squeaks and rattles has resulted in the development of the all-steel closed body on a very large scale in the United States. In 1928 one-half of the automobile bodies manufactured are substantially entirely of metal.

One of the latest and most interesting developments has been the sill-less type of body. In this body, the entire side is made of one piece of steel with the door openings formed in. The entire front: hood, dash, windshield opening, front edge of roof, is formed of one sheet of steel. The entire back, from the bottom to the roof, is made of a single sheet of steel. This body has no floor. The seats are placed on the chassis frame and the sides of the body are mounted directly on the chassis frame—the body serving as a cover for the passengers only.

Upholstery.—In the wooden frame body, the upholstery is attached to the body after it has been built, by skilled operatives, using tacks to hold the material in place and covering the line of tacks by means of lace or gimp. This requires a high degree of skill on the part of the operative, takes a great deal of time and is expensive. In the steel body there has been developed what is known as removable upholstery.

Painting.—The use of varnishes has been almost entirely superseded by the use of cellulose coatings. This is commonly applied by means of pneumatic sprays, several coats being applied as the body moves along the conveyor lines. The coats can be applied one after the other at intervals of 15 to 30 minutes. In the interim, from one spray to another, the bodies pass through ovens where the drying is hastened and the lacquer is somewhat hardened before receiving the succeeding coat. After the several coats have been applied they are polished by vigorous rubbing on the part of the operative. (E. G. BU.)

MOTOR CAR ENGINES: THEIR OPERATION AND CARE. An internal combustion engine is one in which the fuel is burned directly inside the machine which converts the heat energy into work. Practically all motor cars use this kind of engine, the fuel being petrol (gasolene). The engine consists of a number of cylinders. In each cylinder a piston slides up and down. A rod connects each piston to a special shaft, which runs lengthwise of the engine. This is the crankshaft, which carries the flywheel. When the pistons are pushed down, they rotate the crankshaft and this turns the flywheel. In engines having a heavy flywheel, it is here that the power of the engine is stored, and from here the clutch and transmission take it to the rear wheels, which drive the car.

The easiest way to understand how an engine works is to keep in mind only one cylinder. For the engine to run and do work, certain things must take place over and over again in a regular order. The fuel must be sucked in, it must be compressed and exploded; the resulting gases expand, owing to the heat generated, and thus do work, and after expansion they must be removed. These steps make up what is known as a cycle; in the modern engine it takes four strokes of the piston to make up one cycle. During this time the crankshaft will have made two complete revolutions. This type of engine is said to operate on a four-stroke cycle. The four strokes of the piston are named according to what they accomplish. The first is the suction, the second the compression, the third the power, and the fourth the exhaust stroke.

At the start of the suction stroke, the piston is at the top of the cylinder. It moves downward and the inlet valve opens. This sucks in the charge of gases from the carburettor. The compression stroke starts when the inlet valve closes and the piston is moving upward. The mixture is ignited while under pressure by a high tension electric spark, which is produced across the points of the sparking plug, either by means of a battery and coil (*see* INDUCTION COIL), as in American cars, or by a high tension magneto (*q.v.*), as in British cars. The power stroke begins with a downward thrust of the piston. The burning of the gases gives off heat, which causes expansion. Pressure is thus exerted on the piston, forcing it downward as far as it will go. This completes the power stroke. The last movement of the piston is the exhaust stroke. The exhaust valve opens toward the end of the power stroke and most of the burnt gases rush out. The piston moves upward, pushing the remaining gases out of the cylinder. The four-stroke cycle is now complete. (*See* INTERNAL COMBUSTION ENGINES for more extended treatment.)

Fuel and Carburation.—In order to be utilized by the engine, the petrol (gasolene) must first be atomized by the carburettor (*q.v.*), which introduces into the intake manifold a fine spray of petrol which is mixed thoroughly with the incoming air (generally pre-heated to encourage the evaporation of the fuel droplets). This mixture is sucked into a combustion chamber, where a spark ignites it at the top of the compression stroke. The more intimate the mixture, the faster it burns. It is also the duty of the carburettor to admit the correct amount of air needed to burn the fuel. This is important, for if too much air is present the mixture will be too lean, resulting in a lack of power. The most common fault, however, is the use of a mixture that is too

rich, *i.e.,* one containing so much fuel that there is not enough air present to burn it all. This happens when the choke valve (which cuts off the supply of air to the carburettor) is used too freely. To get the most power out of the engine, a mixture of about 12 to 1 is needed. Most cars on the road are run with a mixture of about 10 to 1, and are sadly in need of carburettor adjustment. Practically all exhaust gases are dangerous as they contain about 7% of carbon monoxide, which is exceedingly poisonous. The engine therefore should not run in a closed garage.

Starting.—Occasionally, owing to the improper functioning or failure of a particular part of the mechanism, the engine will not start. There are then three main lines of investigation to follow:—(1) Is there petrol (gasolene) in the tank and is it being supplied to the carburettor? (2) Is the ignition system in order and producing sparks at the sparking plug? (3) Is the compression poor because of pitted or leaking valves, blown-out gaskets or imperfectly fitting pistons and piston rings? If there is fuel at the carburettor, a good spark and good compression, and yet the engine does not start, it may be that the carburettor is delivering to the engine an air-fuel mixture so rich that it will not fire. If the trouble is due to too rich a mixture push the choke back a little, and the engine will run more smoothly. If, however, during acceleration and warming up the engine "pops back" then the trouble may be that the mixture is too lean. The choke should be pulled out until the spitting stops. Then as soon as the engine is warm, push the choke clear in; the engine will run more efficiently and crankcase dilution will be reduced. If uneven firing persists, the carburettor should be given proper adjustment by a competent carburettor mechanic. More engine trouble results from unwise adjustments of the carburettor than from any other single cause.

Electrical System.—The battery is quickly run down if the car is used a great deal at night, when most of the current generated is consumed by the lights, or if many short runs have been made, which gives a battery no time to build up after frequent use of the starter. When the starter turns the engine over slowly and with much difficulty, it is wise to start the motor with the hand crank, as the starting motor takes a heavy current. In American cars in which coil ignition is employed, when the battery is badly run down, the voltage drop is so great that the battery cannot at the same time actuate the ignition system; when a magneto is fitted, as in European cars, the rate of revolution may be insufficient to produce a spark. The battery should be kept clean and the terminals covered with vaseline to prevent corrosion. The cells should be tested regularly and enough distilled water put in to cover the insulators slightly. If the car is laid up, the battery should be removed and kept charged. (*See* ACCUMULATORS.) The ammeter, usually fitted on the dash-board, indicates whether the battery is being charged or discharged. When the lighting, dynamo and ignition switches are turned off, the ammeter should register zero.

Poor performance, excessive consumption of fuel, and misfiring are often caused by dirty, damaged or unevenly adjusted sparking plugs. The sparking plug insulator should be well cleaned. It is well to use the plug recommended by the manufacturer of the car, and to change plugs at stated mileage intervals, since deterioration of porcelain insulators may cause leakage of current, resulting in a weak spark. To discover a defective plug, short-circuit each plug one after another by holding screw-driver or hammer so as to touch the metal or terminal of the spark plug and the metal of the cylinder at the same time. If, when any one plug is short-circuited, no difference is noted in the running of the engine, that particular spark plug may be at fault. Other defects in ignition causing engine trouble are the following:—switch not on; fuse burnt out; disconnected wire on switch, ammeter or battery; and spark retarded or advanced too far. In the case of coil ignition, the coil may be defective or the resistance burnt out, or the contact breaker points may be dirty, pitted or burnt. Where a magneto is used the following may be the source of the trouble:—dirty magneto contact breaker points, contact breaker sticking, gap incorrect, or condenser short-circuiting. (*See* MAGNETO.)

Cooling.—Two systems of cooling motor car engines are used: (1) by air and (2) by water. The cooling of an engine by air depends on the surface exposed, on the temperature of the air and on its volume. To give a large surface for radiation, fins are provided on the cylinders. Most motor car engines are cooled by water which circulates through jackets around the cylinders. After it takes up heat from the engine it passes to the radiator where it is cooled by air. In some cases the draught is aided by a fan. In the two commonest types of cooling systems (*a*) a pump provides forced circulation of the water or (*b*) the principle of the thermosyphon is employed. (*a*) The pump is geared to the engine so that when the engine is running the water must circulate. Even if the radiator is not full the pump will operate and, except in the case where only a very small amount of water is present, overheating will be prevented. In cold weather, the circulation of the water is at the same rate as in hot weather since it depends only on the speed of the engine. As a result, the engine on cold days will not reach a high enough temperature to operate efficiently. To aid in overcoming this condition, a thermostat (*q.v.*) is sometimes used to control the amount of water which is circulated by the pump; the use of the thermostat is not advisable when the circulation is promoted by means of the thermosyphon. (*b*) In the case of the thermosyphon, the hot water from the cylinder jacket passes from the top of the jacket to the top of the radiator where it cools and, becoming denser, falls to the bottom; in the meantime previously cooled water from the bottom of the radiator has passed back to the bottom of the cylinder jacket.

Freezing of the water in the cooling system may cause leaks in the radiator, and may crack the engine block. Methanol, formerly known as wood alcohol, denatured alcohol, glycerine and ethylene glycol are often mixed with the water in the radiator to lower its freezing point. Of these liquids, however, the first two are easily lost by evaporation. A radiator shutter, or winter front, may be used to limit the amount of air which the fan pulls through the radiator, thus aiding in keeping the engine warm in cold weather. Evaporative cooling, used with many stationary farm engines, has not as yet been used on the road, except experimentally.

Lubrication.—A problem that confronts every motorist is dilution, the thinning of the oil in the crankcase. Prolonged use of the choke, particularly in cold weather, is a large factor in causing dilution. Any excess of fuel that is drawn into the cylinders may become mixed with the oil in the crankcase. The lower temperature at which the engines usually operate during the winter also causes dilution. The condition may continue until the amount of dilution of the oil becomes constant, because some of the diluent may evaporate when the oil gets hot, as, for example, during a long trip. A large amount of water is formed by the combustion of the gasolene, and it sometimes finds its way into the crankcase, because of the low operating temperature. Excessive dilution will result in rapid wear of the cylinder walls and bearings, as the oil film on the bearings will not be thick enough to prevent actual contact between the metal surfaces. It should be noted, however, that in cold weather a slight amount of dilution may protect the motor during the warming-up period, for if the oil is extremely thick it might not flow to the bearings. For this reason a cold engine should not be raced to warm it up quickly. Failure to observe this precaution often results in the scoring of the cylinder walls and pistons. The manufacturers' directions should be followed in regard to the proper interval for changing the oil in the crankcase. Before adding the new oil it is inadvisable to use kerosene to wash out the crankcase, because such a procedure would dilute the oil before it is used.

It is the duty of a lubricating system to keep a thin film of clean suitable oil between all metal surfaces which move against each other. Lack of oil will cause friction and abrasion; particles of dirt in the oil will scratch the surfaces and destroy the precise fitting of parts. The film forms only after the engine has been running for a short time, and for this reason the motor should never be raced on starting. There are several different ways of lubricating the engine. In all systems a supply of oil is held in the

bottom of the crankcase. The oil is conducted to the various bearing surfaces by either splashing, pumping under pressure, or by a combination of both systems. The oil gauge is the nerve centre of the engine. If the gauge shows no pressure, it is dangerous to drive the machine farther. If the gauge indicates very low pressure, there is good reason to believe that the oil is flowing through the bearings too rapidly. This may mean that the oil is too thin and diluted, or that the bearings are too loose. If the gauge fluctuates, this symptom of distress signifies that there is probably not enough oil in the system, that the system is choked or that the pump is in need of repair. In any case, irregularities in the operation of the gauge should be taken as the forerunner of trouble and should be investigated immediately. The following are a few rules for the lubrication of a motor car engine:—(1) Keep the crankcase filled to the proper level with oil of the grade recommended by a good oil company. Do not fill beyond the proper level, as this will make the engine sluggish, and in some cases cause sticking of the valves. (2) Change the oil at regular intervals to ensure longer life to the engine. (3) When driving, watch the oil gauge for possible failure in the lubricating system. (4) Keep the engine clean and inspect the air, fuel and oil cleaners regularly. (5) When the engine is old and bearings and piston fits are loose do not expect heavier oil to correct these defects. Have the motor repaired. (6) Do not race a cold engine. (7) Use an oil that will flow freely in winter weather. (8) Do not drive a new machine fast or allow it to overheat. One quart of light oil per 10 gal. of gasolene, poured directly into the fuel tank, may help a great deal during the first few hundred miles of driving. (9) Do not wait until you hear a squeak before lubricating the engine. A squeak means a dry or dirty bearing.

Carbon Deposits in the Engine.—In the process of lubrication, some of the oil, in the form of spray, gets past the piston rings in the cylinders and enters the combustion chamber. This oil causes carbon deposits. The so-called asphalt base (naphthene) oils have been found to leave the least carbon in the engine. As carbon accumulates it makes itself known by loss of power and knocking of the engine, especially on a hard pull, as in climbing a hill. The carbon on the inside of the chamber, on top of the piston and sometimes below the piston, keeps the heat in the combustion space, causing the knocking. Sometimes the carbon itself gets so hot that it burns or glows, exploding the charge of fuel before the proper time. This produces the pre-ignition knock which involves a great loss of power. Sometimes pieces of carbon get between a valve and the valve seat, holding the valve open. When the exhaust valve is thus held open, the flame of the explosion can pass completely around it, burning or warping the valve.

The best way to remove carbon is to take off the cylinder head of the engine and scrape out the deposit. The valves should be ground while the head is off and the gaps on the spark plugs reset. Before replacing the head every particle of loose carbon or grinding compound should be removed to avoid scratching the cylinder walls, and a new gasket put in between the head and cylinder block. Carbon troubles may be minimized in the following ways:—(1) by using an oil of low carbon-depositing tendency; (2) by operating the engine on a lean air-fuel mixture; (3) by running the engine at a sufficiently high operating temperature and giving it a little real work once in a while; (4) by use of an efficient air cleaner; (5) by use of anti-knock fuels when necessary; (6) by keeping the engines in such mechanical condition that oil consumption is not excessive. (W. A. Ha.)

MOTORCYCLES. Although the motorcycle did not become popular in any country until 1911–12, the first examples of it were seen in France and Germany about 1885. In 1907, the first of a series of famous motorcycle road races, the International Tourist Trophy races, was held in the Isle of Man. The importance of winning this race urged designers to improve their machines, as regards both speed and reliability, and from then until 1914, the first year of the World War, the production of motorcycles increased by leaps and bounds. The necessity for the manufacture of war materials, and the difficulty of obtaining petrol then reduced the combatant countries' production of motorcycles to a minimum, but in America an increasing number of machines were made. There was a tremendous demand for motorcycles in the years 1919–20, but British manufacturers, disorganized by war work, were unable to meet it. In 1919 America sold 1,481 motorcycles to Great Britain, and in 1920, 4,277. The numbers then dropped until, in 1926, they reached the low figure of 75, whereas in the same year 48,391 motorcycles were exported by Great Britain and 628,955 were registered for use in that country. Great Britain is by far the largest producer of motorcycles, the output for 1926 being approximately 120,000. Germany comes second with about half this number, America third with some 45,000, and France fourth with 25,000. The figures taken are for the years 1925–26. Italy, Belgium, Austria, Switzerland and Sweden complete the list of the chief manufacturing countries, although many other countries assemble machines.

Stages in Improvements.—The advance in the motorcycle's utility can be marked by three distinct steps. The first was the discovery that the best position for the engine was in the centre of the frame, rather nearer the front wheel than the back, and the adoption of this fixing; the second was the advent of electrical ignition; and the third was the use of efficient chain transmission through a change-speed gear-box. Many other improvements, such as those relating to carburization, frame design, etc., were effected, but the three mentioned above were outstanding in the resultant popularity of the motorcycle. There was no definite position in which one might expect to find the 19th century motorcycle's engine. On some machines it was carried in front of the steering head and drove the front wheel; on others it was attached to the down tube from the steering head, being either in front of or behind it; the seat pillar tube, again, sometimes carried it, whilst on a few machines the power unit was built up into the back wheel or placed immediately above it. In all except the first position mentioned the power was transmitted to the rear wheel. Early in the present century it became acknowledged that the most suitable position for the engine was low down in the frame, just in front of the pedalling gear. In most cases the crank-case of the engine was bolted into the frame, and thus formed part of it, but on a few machines and notably the American "Indian" the down tube from the steering head was continued below the engine. This pattern was known as a loop frame, and although it was little in evidence for many years it is to be found in an improved form on many modern machines.

The problem of ignition of the petrol vapour was one which had puzzled designers from the earliest days of the internal combustion engine. The first form of ignition consisted of a tube protruding from the cylinder, the rider having to heat its external end by means of a Bunsen burner using petrol fuel, before the engine could be started. Towards the end of the nineteenth century, this system, which was known as "tube ignition," was replaced by electrical ignition, composed of a battery, coil, contact breaker and sparking plug. The first electrical system was greatly in advance of tube ignition, but in its early form it was by no means trouble-free, and it was not until the advent in 1903–04 of the magneto, an instrument which generated current when it was rotated, that the motorcycle became a practicable means of transport. Until then the machine as a whole was extremely unreliable, and the rider could never be sure of concluding a run under the power of his own engine. Even when the magneto had marked a reasonable degree of reliability, the motorcycle was still suitable for young and active men only, owing to the inadequacy of its transmission system.

The Advent of Variable Gears.—When the pedal cycle with a three-speed hub-gear, and the motor car with a three or four-speed gear-box were in common use, the motorcycle was still devoid of change-speed gears, and was driven by a single belt. There were, of course, exceptions, one of which was the two-speed chain-driven P. & M., first produced in 1902. Engine power on the earliest machines was transferred to the front or back wheel by means of a twisted leather belt. This soon proved inadequate for the increasing power of new engines, and "V" sec-

tion belts were employed, the angle formed by the two driving surfaces being 28°. These "V" belts were built up either of leather or of rubber surrounding a fabric core. Leather belts were harsh and wore the driving pulleys quickly and rubber belts slipped badly when they became wet. The failings of both were thus very marked, and since they connected the engine direct to the back wheel, the former could not run unless the motorcycle also were in motion. This meant that the only way to start the machine was for the rider to push it at a speed of 6–8 miles per hour and to jump on as soon as the engine fired, an athletic procedure which could only be indulged in by a small section of the community. To understand the motorcycle's lack of development in this respect, it is necessary to consider the type of engine used. This was in most cases a four-stroke of either single or twin-cylinder pattern. (*See* INTERNAL COMBUSTION ENGINE.) As the power impulses of the engines were too harsh to be transmitted to the rear wheel by chain or other such appliance, it was necessary to have a driving element capable of absorbing the shock of the explosions, and a belt, which provided a certain amount of elasticity, proved the easiest solution of the difficulty. With the single belt, an unpleasant but inevitable component, the only place to fit change-speed gears was the hub of the rear wheel. Various two- and three-speed hub gears were made during the early part of the 20th century, each of these incorporating a clutch, a slipping device for allowing the power of the engine to be applied gradually to the rear wheel, so that the machine would start under its own power. Hub gears, however, proved to be very unsuitable, since their internal parts could not be made large enough to withstand the strain. Designers, therefore, applied themselves to the production of counter-shaft gear-boxes—so called because the gear wheels work on more than one shaft, as opposed to epicyclic gears which employ a common shaft —usually placed just behind the engine. With a few exceptions, the early counter-shaft gear-box was driven by a chain from the engine, an ordinary "V" belt connecting it to the rear wheel. This type of transmission was much in favour in 1914, when the outbreak of war stopped further experiments in motorcycles. Belt trouble was still existent, but, since the belt ran in larger pulleys than was the case with a single-belt drive, it was not so marked. Shortly after the war, however, machines with all-chain drive became almost universal, a device to absorb the shock of the engine being fitted on the engine shaft, in the gear-box or in the rear wheel. This type of transmission or one which replaces the primary chain by gear-wheels, together with many other improvements, has made the modern motorcycle a most efficient piece of engineering and suitable for riders of either sex. It can be ridden by anyone who is in possession of normal physical and mental powers, and it is a cheap form of mechanical transport.

Types and Sizes of Engines Used.—As has already been mentioned, most motorcycles employ single- or twin-cylinder engines. This rule may be said to apply to machines all over the world, except in the U.S.A. where a few four-cylinder motorcycles are made. Apart from this small number of cylinders, most motorcycle and motor car engines are similar in general design (*see* INTERNAL COMBUSTION ENGINE), and are of the four-stroke type. Many motorcycles, however, are fitted with a type of engine little used for cars, the two-stroke. The two-stroke engine fires on every revolution, instead of every alternate revolution as does the four-stroke, and its power impulse is thus more smooth. It is extremely simple and reliable, in that it has only three moving parts, but it has certain defects, and it does not develop more power than the four-stroke. The earliest two-stroke to be placed on the British market was the twin-cylinder water-cooled Scott (1909), the first air-cooled two-stroke being the Levis which made its appearance a year later. Races and reliability trials have done much to improve the motorcycle, and the modern machine has a low centre of gravity, a smooth running and relatively well-silenced engine, large pneumatic tyres, a three-speed gear-box with a handle-bar controlled clutch, a kick-starter and all-chain drive, efficient internal expanding brakes, a well-sprung saddle and front forks, and mudguards which give a moderate degree of protection. Electric lighting sets came into general use in 1927, and almost any machine can be obtained with one at a small extra charge.

Motorcycles are made in all sizes from about 1·5 to 12 h.p., and a machine of 3·5 h.p. or more is capable of taking a side-car. The side-car is attached to the left side of the machine in Great Britain, and to the right side in the United States, according to the rule of the road of the country in which the outfit is being used. In most countries, however, there is no law prohibiting the fitment of the side-car on what is considered locally to be the wrong side. Horse-power is reckoned on the capacity of the engine; *i.e.,* the volume swept by the piston or pistons, in cubic centimetres, 100 c.c. being considered equal to one horse-power. Thus an engine with a capacity of 350 c.c. is stated to have a horse-power of 3·5, and so on. Some manufacturers, however, cling to horse-power denominations based on an old and inaccurate rating. In America the most favoured type of motorcycle is the large twin- or four-cylinder machine of 10–12 h.p., for either solo or side-car use, but in Great Britain and most European countries solo machines of above 5 h.p. are not widely used, the larger sizes generally being employed with side-cars. Machines of from 1·5 to 2·5 h.p. are very popular in Europe or wherever the roads are moderately smooth, since they are light and easily handled, but in districts where roads are poorly constructed the larger sizes are usually chosen.

British Racing Successes.—At the beginning of 1928, the majority of racing successes stood to Britain's credit. Every international tourist trophy race except one (the 1911 5 h.p. class, in which an American "Indian" was successful) had been won by a British motorcycle, and in most continental grand prix races when British motorcycles were present they had proved themselves to be infinitely superior to their competitors. As an indication of the increase of speeds in recent years it is interesting to note that whereas the first tourist trophy race (1907) was won at 38 miles per hour, the 1927 race, on a larger and more difficult course, was won at 68 miles per hour. Most of the world's records for high speeds are held by British machines.

The following is a list of record speeds over a distance of one kilometre, up to the end of 1927.

Solo motor cycles: 2·5 h.p. 89·96 m.p.h.; 3·5 h.p. 102·99 m.p.h.; 5 h.p. 114·02 m.p.h.; 10 h.p. 121·41 m.p.h.

Side-car machines: 6 h.p. 99·07 m.p.h.; 10 h.p., 104·12 m.p.h.

The 5 h.p. solo and 6 h.p. side-car records are held by Belgian motorcycles, the remainder of the records standing to the credit of Great Britain.

UNITED STATES

The modern American motorcycle is constructed according to the service for which it is intended. The light type consists usually of a single cylinder, four-cycle engine with a chain transmission and weighs from 225 to 275 pounds. This motorcycle, intended for solo use only, is a very economical means of transportation. The motors are usually of 21 cu.in. capacity and will develop from 8 to 12 h.p., according to type; they operate regularly on a gasolene consumption of one gallon per 80 to 100 m. and up to a speed of 55 m. per hour. There has also been developed a medium-weight type for solo use. This has either chain or gear and chain transmission. The motor of the two cylinder type is from 37 to 45 cu.in. and will develop as high as 16 horse-power. This motorcycle will run at speeds up to 70 m. an hour and has a gasolene consumption of one gallon per 60 to 80 miles. The heavy type of motorcycle is used in police and commercial work, for pleasure, both solo and with side-car, and has also found a useful place in the army.

For police work the motorcycle becomes indispensable. The enormous increase of the use of the motor car, greatly encouraged by improved roads, has diversified police use in many ways. In

many States police bodies have been organized and equipped with motorcycles as a ready means of performing their duties. Their work consists of the regular police work and the prevention of reckless and careless driving. In the city, the motorcycle police officer, in addition to enforcing the driving and traffic laws, is able to respond with great quickness to emergency calls. The motorcycle as a necessity to the mounted officer is universally recognized and provides a mount which has capabilities beyond any other that is available for enforcing speed laws and regulation of traffic.

In the army, the motorcycle has proved its worth as a means of rapid communication in rough country and for its ability to thread its way through congested traffic such as occurs when large bodies of men and supplies are moved from place to place. Many thousands of motorcycles were used in the World War. When the army organization tables were recast some time after the war, motorcycles were provided for various units. The motorcycle is still being used for pleasure, but not to the extent that it formerly was. Its appeal lies to the young man between 18 and 25 and forms a rapid means of transportation and exhilarating sport. The motorcycle production in the United States reached its peak in 1913, and in that year a total of 70,000 motorcycles were made. The production for the last three years, up to 1928, has been 45,000 annually. There are six companies manufacturing motorcycles in the United States at the present time. (W. S. H.)

Motorcycle Racing in the United States.—The first real fast time established in the United States was made by the late Albert Champion, who covered a mile on a track in 1 min. 10⅘ sec. in 1902. Oscar Hedstrom, designer of a motorcycle and bicycle bearing his name, rode a mile on the Florida sands on an Indian machine he designed, in 1 min. 3⅕ sec.

Real competition came after the formation in 1903 of the Federation of American Motorcyclists, an association organized for the purpose of furthering the interests of the motorcyclists and the control of motorcycle competition. Almost at once race meets were promoted throughout the country with the then well-known Jake DeRosier, Walter Goerke, Frank Hart John U. Constant, Ben Swenson, Glen H. Curtiss, J. I. Brandenburg, Stanley Kellogg and many others.

With the advent of racing on a large scale the manufacturers built special racing machines to insure the name of their product being among the first three in the summaries. Speeds began to increase and trials for a "mile-a-minute" were made. Racing was held on dirt or horse-racing tracks, in the earlier days. Then, about 1911–13, came the board tracks, or the so-called motordromes and a circuit of such tracks, generally from ¼ to ⅓ m., sometimes ½ m., was established. But this form of motorcycle racing was soon abandoned due to the number of fatalities. Racing then went back to the horse tracks and later to the automobile speedways, of a mile or so. What racing is being done to-day is held either on horse tracks or on the automobile speedways. Most motorcycle competition work is confined to hill climbs, racing having been dropped by a number of factories. The control of racing is now handled by the American Motorcycle Association.

The A.M.A. records show that Jim Davis, at Beverly Hills Speedway, Los Angeles, Cal., did a mile in 32·43 sec. in 1922. Three years later at Laurel, Md., his time for 5 m. was 2 min. 41⅗ sec. Joe Petrali at Laurel did 10 m. in 5 min. 23⅘ sec.; 25 m. in 14 min. 8⅗ sec. and 100 m. in 59 min. 47⅕ sec., or better than a mile a minute for the entire distance. Records by R. Hepburn on a dirt course at Dodge City, Kan., in 1921, stand at 2 hr., 17 min. 54 sec. for 200 m. and 3 hr. 30 min. and 3 sec. for the 300 miles.

Record beach performances at Daytona Beach in 1920 stand as follows: 1 kilometre by Gene Walker in 19·32 sec. or 115·79 m. per hour; 1 m. by Gene Walker in 31·53 sec. or 114·17 m. per hour. (W. A. Ba.)

MOTORING. The increase in the popularity of private motoring is one of the most remarkable developments of modern times. Assuming that there were 1,300,000 motor-cars and motorcycles in use in Great Britain in May 1928, the total value at even £100 apiece—a very reasonable estimate—would have amounted to 130 millions sterling. If these 1,300,000 vehicles covered 5,000 miles a year, or on the average say 100 miles a week, it would work out that 6,500,000,000 miles are covered in a year by motorists in Great Britain alone, or about 70 times the distance of the sun from the earth! In 1897 less than twenty people, all of them enthusiasts, daily execrated by the public at large, possessed a private motor vehicle. But the private owner can no longer be regarded as using a car for pleasure only. Every day use for every day purposes is now the usual work of a privately owned car. Prior to the World War, motoring was to some extent confined to well-to-do people, whereas to-day the majority of motorists are people of quite moderate or even very limited means. People possess and use cars to-day not so much because they want to as because they must do so. In short, the question is not so much whether a person can afford a motor car as whether he can afford to be without one.

Causes of Rapid Growth.—Apart from the great demands of business, the very rapid recent growth of motoring has been due to factors which may be enumerated as follows:—(1) Cheap prices for really good cars; (2) the adoption of the hire purchase or "purchase out of income" system; (3) improvement in the quality of both mechanism and tyres, resulting in reduced maintenance charges; (4) improved engine efficiency resulting in reduced fuel consumption and lowered running costs.

Dealing with the factors categorically we find:—(1) Owing to the very large increase in wages subsequent to the World War, and the corresponding increase in the cost of all manufactured articles, it became necessary to study and apply scientific methods of production to a much greater extent than had previously been considered necessary, for it is a well-known fact that when labour is both cheap and plentiful there is less incentive than when wages are high to pay attention to this matter. Hence since the war it has come about that partly at least owing to much higher wages prevailing the introduction of more scientific methods of production has revolutionized many industries, to their great advantage, and this change has been particularly evident in the motor manufacturing and affiliated trades.

(2) The introduction of the hire purchase system in regard to motor-cars has resulted in large numbers of persons joining the ranks of motorists who would not have done so had it not been for this convenient method of extended credit. The economic pros and cons of the system need not be considered here. It is sufficient to say that the hire purchase of pianos, furniture, houses, etc., has been in existence for many years and that it has certainly been responsible more recently for an enormous increase in the number of motor vehicles in use. There are, in fact, thousands and thousands of young professional and business men to-day to whom the motor-car or cycle has become literally a necessity and the hire purchase system has provided them with an easy means of obtaining their equipment.

(3) Just in the same way as increased demand and larger output, as the result of scientific production, have enabled prices to be reduced, so improvements both in design and equipment have similarly resulted. Wheels, tyres, transmission gears, brakes and electric equipment are all more efficient, while lubrication, which was at one time not only a dirty business but also little understood by the average owner, has now been arranged so as to render it practically automatic and fool-proof. Tyres give much longer mileages than previously, which may be attributed partly to the improvement in the quality of the tyres, and to a very large extent also, to the improvement in the quality of road surfaces. Gears have longer lives because in the first place they are better designed, and, in the second place, because the steel from which they are made has been greatly improved in quality.

(4) The improvement in engine efficiency has been particularly marked. Efficiency in this respect means the amount of power derived from the engine which is transmitted to the road surface, in relation to the power put into the engine in the form of petrol or other fuel. A modern engine of good class will give on a gallon of petrol double the mileage which an engine of similar dimensions would have given only a few years ago.

CARS IN GREAT BRITAIN

The following special table shows the number of private cars in use from 1911 to 1927 together with the annual percentage increase and number of persons per car in Great Britain. Previous to 1911 the various types of motor vehicles in use had not been classified.

Great Britain: Proportion of Private Cars in Use to Total Population: 1911–1927

Year	Private cars in use	Population per car	Annual increase or decrease of cars in use, per cent
1911	47,000	862·8	..
1912	57,000	717·5	+ 21·3
1913	68,000	602·0	+ 19·3
1914	85,000	486·1	+ 25·0
1915	90,000	463·5	+ 5·8
1916	92,000	435·5	+ 2·2
1917	71,000	555·5	− 22·8
1918	50,000	780·3	− 29·5
1919	71,000	547·1	+ 42·0
1920	122,000	318·8	+ 71·9
1921	250,000	168·3	+105·0
1922	315,000	135·6	+ 26·0
1923	384,000	112·1	+ 21·9
1924	474,000	91·3	+ 23·4
1925	580,000	75·1	+ 22·3
1926	686,000	63·9	+ 18·2
1927	727,000	..	..

The figure 63·9 persons per private car given in the foregoing table for Great Britain in 1926 compares as follows with other principal motor using countries.

	No. of persons per private car
United States	6·0
Canada	12·9
New Zealand*	13·3
Australia*	19·7
South Africa*	21·4
Great Britain	63·9
France	69·1
Germany	313·0
Italy	495·8

*White population only.

Classification by H.P.—A return issued by the Ministry of Transport showing the number of vehicles bearing current licences during the quarter ending Sept. 30, 1927 shows the classification in respect of horse power. The table given in the next column is not up-to-date, but it is the latest available, and is very interesting as showing the degree of popularity of each. (*See* also MOTOR CYCLES.)

Great Britain—Analysis of Total Number of Mechanically-propelled Private Motor Cars and Cycles for Which Licences Were Current at Any Time during the Quarter Ended Sept. 30, 1927.

Description	1927	1926
A.—Cars taxed on horse power

Freedom of Residence.—There is yet another matter having a very important bearing on the continually increasing use of the motor car, namely the greater freedom which it affords as regards choice of residence. First, the motor car appealed as a means whereby the town dweller could get out into the country, especially at week-ends, for both pleasure and health. Any train journey involves starting at a fixed time, with tedious waiting sometimes for train connections, and, in the case of the family man, the accompanying anxiety and worry of tired and peevish children and nervous strain on all concerned. These contingencies in connection with "a day in the country" or a week-end were sufficiently serious to weigh heavily with most so that more often than not it was judged preferable to stay at home rather than face such trials. With the coming of the motor car all this was entirely changed. That which was formerly a serious undertaking has now become an unalloyed pleasure. Those who make their journeys by car instead of by train gain thereby greater freedom, reduced cost and, very often, reduced expenditure of time also. Further, the average town dweller is no longer tied down for residence to the close neighbourhood of his business, with the probable incidentals of high rents and rates. He can now go further afield—to the country which, until then, had been to him more of a legend than a real fact. The migration thus set up is still in progress, and in England is evidenced by what is known, and also deplored, as the "ribbon" development along our highways, otherwise the tendency of houses to stretch out unduly along the frontages of the main roads. From a health point of view there is good in this new development, but control is needed to preserve the amenities of the countryside. And if care is not

exercised by the highway authorities main trunk roads will become long drawn out suburbs instead of high speed roadways and much of the expected advantage will be lost.

LAWS AND REGULATIONS

The laws and regulations governing the use of motor-cars are of various kinds.

Driving Licences.—In Great Britain, before driving a car or a motor cycle a licence must be obtained from the county council or borough council, the fee for which is 5/–. In the Irish Free State it is 10/–. Councils have no power to refuse a licence except under a magistrate's order, in consequence of a conviction for a road offence, suspending or declaring an applicant incapable of holding a licence. The licence must be renewed each year and it must be produced on demand by a police officer. If a licence is lost a duplicate may be obtained for 1/–. A driving licence is obtainable by anyone above the age of seventeen or, for a motor cycle, above the age of fourteen.

Registration.—Before a car or motor cycle may be used on the road it must be registered with a county council or borough council. The council at the same time assigns an identification number. A number plate, of a size and with letters and numbers prescribed by regulations, must be carried at the front and at the back of the car. Motor cycles may carry plates of half size and the front plate may be lettered on both sides and carried so as to be read from either side.

For the purpose of registration, the registration authority requires the following information:—(1) the present registration mark and number, if any; (2) type of body; (3) colour of body and wheels; (4) name of maker, type of car, chassis and engine numbers; (5) year of manufacture, if possible; (6) number and diameter of cylinders.

On registration the owner of each vehicle is provided with a registration book, which—

(1) must be handed on any change of ownership to the transferee, who on receipt must send it to the local council (Minister of Transport Regulations, 1924) which must also be notified by the former owner.

(2) must be produced on reasonable notice, though it need not be carried in the car.

The position of the licence card, in the case of motor cycles, in a conspicuous position on the near side of the vehicle in front of the driving seat; in the case of a motor cycle with sidecar, on the near side of the handlebar of the cycle or the near side of the combination in front of the driving seat; in the case of all other vehicles (except when placed on or adjacent to the windscreen), on the near side of the vehicle facing toward the near side and not less than 2 ft. 6 in. nor more than 6 ft. 6 in. from the ground level.

In the case of a vehicle fitted with a front glass windscreen, the licence may be carried facing forwards on the near side lower corner of the glass, so as to be clearly visible from in front at all times during daylight.

Full particulars concerning the issue of licences for motor cars are contained in the Road Vehicles (Registration and Licensing) Regulations, 1924.

Motor Car Licence.—The taxes payable in respect of these are as follows:—in respect of private and other "horsepower taxed" cars, not exceeding 6 h.p., or those electrically propelled, £6 per annum; in respect of those exceeding 6 h.p. £1 per annum for each unit or part of a unit of horse power.

The Royal Automobile Club formula, which has also been adopted by the British Government for the purpose of motor taxation, *i.e.*, for the determination of horse power, is $D^2 \times N \div 2\cdot5$, in which D=diameter of cylinder in inches and N=the number of cylinders. For millimetre dimensions the formula is:—$D^2 \times N \div 1{,}613$. The formula does not take into consideration the question of stroke.

A licence may be taken out for a motor car or any mechanically propelled vehicle, for one quarter of the year only beginning on Jan. 1, March 25, July 1 or Oct. 1, the duty in this case being $27\frac{1}{2}\%$ of the full annual value.

A licence may also be taken out for shorter periods but the licence in these cases must expire on the last day of the quarter, the duties payable being—(1) Full quarter duty if over two months; (2) Two-thirds of quarter duty if over one month to run; (3) One-third duty if under one month to run.

Warning Signals and Lamps.—A bell or other instrument of warning must be carried on every motor vehicle, by which the driver may give audible and sufficient warning of the approach or position of the car.

By the Road Transport Lighting Act 1927, which came into operation on April 22, 1928 the lighting requirements prescribed are two lamps showing a white light to the front and one lamp showing a red light to the rear. Motor bicycles are also required to carry a white front light and a red rear one and pedal bicycles and tricycles a white light in front and either a red lamp or red reflector behind.

The hours of darkness or periods during which vehicles must be lighted are defined as being the time between one hour after sunset and one hour before sunrise in "summer time" and, for the remainder of the year, the time between half-an-hour after sunset and half-an-hour before sunrise.

Speed and Noise.—The regulation (1928) with regard to speed is a limit of twenty miles per hour. The driver of a motor vehicle may, however, be prosecuted for reckless driving even if proceeding at a lower speed. The Minister of Transport has power further to reduce the speed limit to 10 miles per hour in special places, such places being indicated by notice boards. It hardly needs adding that the 20 mile speed limit is more honored in the breach than the observance.

The driver of a motor car must not wilfully disregard the direction of a police constable in uniform, to stop, or to proceed, or to keep a particular line of traffic. This is the general law under the Public Health Act 1925 (Section 74).

A motor car must have two independent brakes in good working order, so that the application of either shall cause two of its wheels on the same axle to be prevented from revolving. In cars with less than four wheels, "two wheels" means "one wheel."

A motor car must be so constructed that when stationary, the action of the machinery may be stopped so far as is necessary to prevent noise. Further, a car must be so constructed that it will not make sufficient noise to cause a nuisance when passing along the highway. By the Cut-out Order 1912, it is forbidden that any motor car or motor cycle shall be permitted to use a cut-out or any other device which will allow the exhaust gases from the engine to escape into the atmosphere without first passing through a silencer or expansion chamber, suitable and sufficient to reduce the noise which would otherwise be caused as far as may reasonably be practicable.

Insurance and Accidents.—Though there is no law requiring insurance, it is a most important matter, particularly that with regard to what are called third party risks, otherwise injuries caused to others. It must also be remembered that the owner of a car, giving a lift to a friend, is liable for any injury which his friend may sustain, owing to his careless driving. The insurance policy should cover this risk.

As was to be expected, the advent and rapid increase of motor traffic, has led to a very large increase in the number of road accidents. The measures which are being taken to reduce the number include systematic road improvements (widening, straightening out or easing of dangerous bends and so on), the education of both pedestrians and drivers on "Safety First" lines by the National Safety First Council and, in addition, continued improvement in the control mechanism of vehicles.

The table on p. 908 gives the statistics of all recorded road accidents in Great Britain from 1918 to 1927.

In the face of these alarming figures it is comforting to realize that in 1927 the number of accidents, fatal and non-fatal, declined in proportion to total population, vehicles used and miles run. But the education not only of the motor vehicle driver but also of the pedestrian in the principles of "Safety First" must proceed much farther if a really substantial and satisfactory reduction in the number of accidents is to be effected.

(M. OF B.)

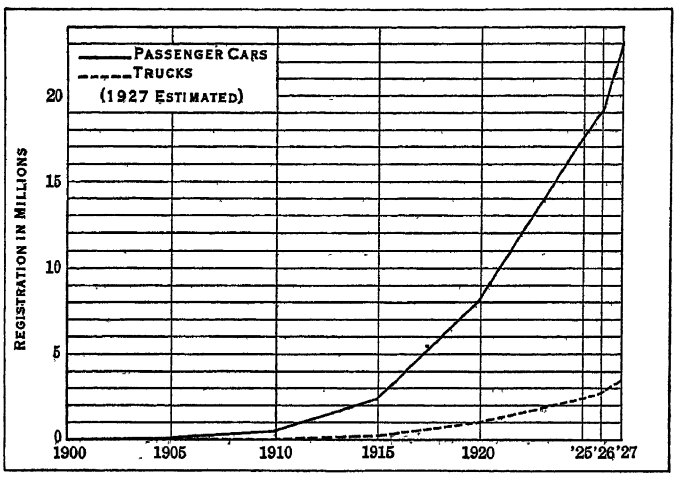
UNITED STATES

A general impression of the present status of motoring in the United States may be obtained from the chart of motor vehicle registrations since 1900.

The inference is that there is one automobile for every six persons in the United States, and at first glance the chart seems to show that there is a great amount of pleasure touring. It raises also the question of how this volume of motor travel can be supported. But as a matter of fact, touring for pleasure is secondary, and there are only one or two clubs in the United States which approximate the service given by the Royal Automobile Club of Great Britain and the Automobile Association. The basis of motoring in the United States has always been the need for transportation, especially in rural communities. From the beginning the most numerous purchasers have been the farmers. The demand for rapid communication in rural regions is clearly indicated by the accompanying table:



GRAPH OF INCREASE IN REGISTRATION SINCE 1900

Distribution of Registration in Rural and Other Communities

(Figures as of December 31, 1926, by courtesy of R. L. Polk Company)

	Per cent		Per cent
Towns under 1,000 including rural . .	28·1	Towns 25,000 to 50,000	6·4
Towns 1,000 to 2,500	11·3	Towns 50,000 to 100,000	6·0
Towns 2,500 to 5,000	8·3	Towns 100,000 to 500,000	11·7
Towns 5,000 to 10,000	7·9	Towns 500,000 and over	11·4
Towns 10,000 to 25,000	8·9	Total	100·0

It is not strictly accurate to state that every sixth person in the United States owns a motor car. Of the 23,000,000 motor vehicles in the United States, 20,000,000 are passenger automobiles. At least 1,500,000 are owned by corporations for the corporate purposes of selling, building inspection and purely commercial ends. It is further true that there are approximately 3,000,000 families in the United States who own more than one automobile. Hence the actual number of families owning motor cars in the United States may not total more than 15,000,000.

It is to be noted that 56% of the automobiles are registered in communities having less than 10,000 population and it is significant that the bureau of public roads is a part of the U.S. department of agriculture. The demand for better highways continues to come from rural regions. The congestion of traffic—mostly motor driven—in the large cities is, to some extent, strictly urban, but various traffic counts have indicated that much, if not most, of it originates in the country districts, for the cities are the market places for the farmer and in many cases they lie athwart the State highway. The bureau of public roads is continually working with the various State Governments to develop a network of highways connecting every community in the United States of 5,000 population or more. Nearly half of the work has been finished, and when completed, this system will comprise about 200,000 m. of well paved roads.

Another side of motoring in the United States is the practice of travelling to and from business by motor car, which has led to a very considerable extension of suburban territory. The motor vehicle registration on Long Island, a suburban region adjacent to New York city, has increased fourfold since 1918. In cities of less than 200,000 population, this method of travelling to work is quite usual. Most of the factories in Detroit and in the outlying sections of other large cities, maintain large spaces where the cars of their employés may be parked during working hours. The worker using an automobile is able to live where land is cheap, and thereby save more than his motor transportation costs.

Touring for Recreation.—In the past few years there has been an increase in recreation touring. Motor camps in the United States number (1928) about 5,000. In addition to this there are thousands of tourist lodges which will accommodate persons for as little as 50 cents per night. These low prices have made touring possible for those who could not afford to stop at regular hotels, and although there were only 29,000 cars registered at the national parks in 1916, by 1920 the number had grown to 406,000 cars. In 1926 15,489,000 motorists visited the national forests. The place of the automobile as a general carrier of the public is indicated by these figures since there were but 1,600,000 visitors to these playgrounds who arrived by other means than car.

Accidents.—Motor travel increased with great rapidity in the period following the World War, and resulted in a great increase in the number of fatalities as is indicated by the following:

Motor Fatalities, 1917–26

Year	Automobile fatalities	Motor vehicle registration	Fatalities per 100,000 registration	Year	Automobile fatalities	Motor vehicle registration	Fatalities per 100,000 registration
1917	9,097	5,104,321	178	1922	13,676	12,238,375	112
1918	9,457	6,146,617	154	1923	16,452	15,092,177	109
1919	9,825	7,565,446	130	1924	17,566	17,593,677	100
1920	11,074	9,231,941	119	1925	19,828	19,954,347	100
1921	12,370	10,463,295	118	1926	20,819	22,001,393	95

The annual total of fatal accidents is still rising, although 14 States and 28 cities in 1926 made a reduction in their total fatalities and it is expected that the 1927 records will indicate still further progress in this direction. As it is, the rate per 100,000 is being steadily reduced. Opinion varies as to the best ways of reducing the accident rate but experience on specific highways indicates that improving the design of the road is very effective; *e.g.*, the Bronx river parkway, on the outskirts of New York city, which has carried as many as 35,000 vehicles on a holiday without an accident. On this road grade separations provide that intersecting highways pass above or underneath the parkway and opposing lines of travel are, for the most part, separated by a strip of landscaping. Furthermore, it is interesting that psychologically roadways which are well "landscaped" have the better safety records. Equally broad roads flanked by shops, signboards and similar distractions are not as safe.

Traffic Codes.—The national Government is co-operating with various national associations to simplify and unify the many different State and city motor vehicle codes. Most of the public schools include safety education in their curricula. "Stop" and "Go" signals are widely distributed. (J. C. L.)

MOTOR RACING. The first motor car competition of any kind, which was not actually a race, though it had some of the

characteristics of one, consisted of a trial from Paris to Rouen and back in 1894. Though only 26 cars competed, the fact that 102 were entered says much for the enthusiasm of the moment. The first prize was divided equally between a Panhard and a Peugeot car. It was after this that racing really began as a serious business. The route generally lay between two big towns along the ordinary highways, a limited number of police afforded meagre protection, dust-laying compound was not used and other traffic was sometimes allowed to stray on the road in the path of the cars. From the driver's point of view this increased the difficulties. It was impossible to practise over the roads and obtain full knowledge of the curves and corners. To pass another car, it was first essential to drive through a blinding dust-cloud, and there was always the possibility of a number of people being in the road round any curve. Moreover, each driver fought alone for his own car; there was no team organization, no organized national rivalry. Of such character were the Paris-Bordeaux, Paris-Berlin and Paris-Vienna races.

The Gordon Bennett Race.—This race, for a trophy presented by James Gordon Bennett, was a different affair. In this a team of three cars represented their country, and it was country against country, not car against car. Also, every part of each machine down to the smallest detail had to be manufactured in the country which it represented. The first two Gordon Bennett races were run as part of other longer competitions. Before the third could be staged a disaster changed the whole organization of racing. The Paris-Madrid, in 1903, was run in the old way over badly guarded main roads in the presence of enormous crowds with cars, which had ceased to be stripped and specially prepared touring cars, and had become very fast racing machines. The terrible series of accidents which occurred because the crowd invaded the road made the French Government stop the race at Bordeaux, and from that time onwards races have been run on a triangular circuit, palisaded on all sides, closely guarded by police and troops, and with a specially prepared road surface. The third Gordon Bennett race in Ireland was the first of this type. In the earlier races, also, big towns were neutralized, the cars going through slowly and resuming racing on the further side, a method adopted in Ireland for the last time.

The Grand Prix.—In 1906 there was another great change. The enormous number of manufacturers engaged in the trade in France resulted in a protest against the Gordon Bennett, as France could only be represented at the most by three types of car. Accordingly, the Grand Prix was organized from 1906 to 1908; in that race the various makes of cars competed against each other, though the national rivalry was maintained; all the cars from one country had to be the same colour, namely, British, green; French, blue; German, white; and Italian, red. These races were extraordinarily popular and were hard-fought battles. In 1909, 1910 and 1911 there was no race, while 1914 put an end to the next series, the last race being notable because the Mercédès firm introduced an efficient system of team control, involving both strategy and tactics.

Post-war Racing.—After the World War Grand Prix racing was resumed in 1921, but it was shorn of much of its former glory, the number of cars entered being greatly reduced, and the last really great race of the series occurred in 1924. Thereafter, the number of competing teams dwindled and practically every year one particular team had such a superiority that the others were in a hopeless position. This led to a resumption of the original type of racing, a 24 hours' race being organized first at Le Mans in 1923, in which the cars had to carry full equipment, namely, lamps, screen, hood and bodies of touring type. This race, which proved a great success, was followed in 1927 by a six hours' race of the same character on the Brooklands track in England. In 1928 the R.A.C. revived the Tourist Trophy Race for fully-equipped sports cars by organizing an event on the Ards circuit, near Belfast; this resulted in a magnificent contest between a great number of different sizes of cars, in which Kaye Don won with a Lea-Francis at 64·06 m.p.h.

Racing Records.—Races to establish records are always run under the same rules. The cars are stripped racing machines built for speed only, and the results are in two categories, the first termed "world's" records, in which the size of engine does not matter, and the second called international class records, in which the cars are grouped according to the size of engine. Records in one class have nothing to do with records in the other.

In America a car with an engine capacity of 91½ cu.in. under American rules has averaged in the same manner 164 m.p.h., and, to give another example of the speed attained by these small cars, which are about the equivalent of the 12 h.p. car of everyday use, the hour in the European class for engines of similar size stands at 115·56 m.p.h. Appended are the results of some of the more important races:—

Date	Drivers	Car	Speed m.p.h.
200-Mile Race			
1921	H. O. D. Segrave	Talbot-Darracq.	88·82

drivers of steam or motor-propelled cars. The races of the earlier days were confined to the small horse-powered car, while the 100 m. an hour cars of to-day make up the entries. Ray Keech, driving a Triplex special, built by a Philadelphian, on April 22, 1928, established an average of 207·552 m. an hour over a one-mile measured course at Daytona Beach, Fla., the highest automobile speed record until March 11, 1929, when H. O. D. Segrave broke the world's record by making an average of 231·362 m. an hour on the same course, in a British-built car.

Automobile racing in the United States is governed by the American Automobile Association. There are races not sanctioned by this association; but records in these so-called "outlaw" races are not recognized by the governing body. In the earlier days of automobile races a number of bicycle-racing men branched out as automobile speed drivers. Among them were Barney Oldfield, one of the pioneers at dirt track racing; Earl Kiser, known as the "Dayton Dumpling" in cycle-racing circles; and somewhat later Ralph De Palma, Frank Galvin, Carl Limberg, Joe Downey and others of equal note. Soon after the first automobile races, which were held on beaches and dirt tracks, there came the road classics such as the Vanderbilt Cup race, the Grand Prix race and the Savannah Grand Prix race. All of these are but history, and the Indianapolis Speedway race, started in 1911 and run every year since with the exception of 1917 and 1918, is the one classic left. The first race was won by Ray Harroun, who averaged 74·59 m. an hour. Then in turn came Dawson, 1912, with 78·7 m.; Gioux, 1913, 96·92; Thomas, 1914, 82·47; De Palma, 1915, 89·94; Resta, 1916, 82·26; Wilcox, 1919, 86·96; Chevrolet, 1920, 88½; Milton, 1921, 89·62; Jimmy Murphy, 1922, 94·48; Milton, again in 1923, 90·95; Corum and Boyer, 1924, 98·28; Peter De Paolo, 1925, making the fastest average, 101·13; Frank Lockhart, 1926, 95·8; George Souders, 1927, 97·54 and Lou Meyer, 1928, 99·482.

Records for automobile racing, as compiled by the Contest Board of the American Automobile Association are classified as: speedway records, 91½ cu.in. displacement, and 122 cu.in. and 1 m. dirt track records. The fastest speedway qualifying record for 1½ m. was held by the late Frank Lockhart made at Atlantic City, on May 7, 1927, when he did a lap of 1½ m. in 36.66 sec., an average of 147·729 m. per hour. Lockhart also had the best dirt-track qualifying mark, which he made at Cleveland on Sept. 26, 1927, doing the mile in 38·94 sec., an average of 92·46 m. an hour. The speedway records for standard distances, 5–500 m., are:—

Speedway—91·5 cu.in. Displacement

5	3:28·12	86·488	100	1:14:14·50	80·817

(W. A. Ba.)

TRACK RACING

The first racing track to be built was that at Brooklands, near London, completed in 1907. Though road racing was already popular on the European continent, there were no facilities for this type of racing in England, and consequently the development of English motor cars was behind that of the Continental cars, which benefited by the tests carried out at comparatively high speeds. Locke-King, therefore, built the track at Brooklands, Surrey, primarily to enable manufacturers to investigate problems in the design of the ordinary touring car by means of intensive high-speed tests.

The ordinary touring car owes its reliability to the experience gained comparatively quickly on a track, where the conditions of fast travelling reproduce approximately the fatigue which results from prolonged use at ordinary speeds. In order to encourage manufacturers to use racing tracks for these tests, records were kept of the various distances covered in the short times by different classes of car. This promoted competition between the manufacturers, and led to the development of track racing as a sport which attracted the general public.

The second track to be built was that at Indianapolis (1911). This, in common with other tracks that have since been constructed in America, is used for racing only. In contrast with Brooklands, where there are several race meetings every year, besides manufacturers' trials, at Indianapolis there is one annual race meeting, which, however, is attended by a vast number of people from all parts of the United States, the competitors being representatives of the various racing centres. The necessity for racing tracks on the Continent was not felt until after the World War, and the first of these, the Linas-Montlhéry track, near Paris, was opened in 1924, and was followed by several others, notably the Monza track, near Milan, and one at San Sebastian in Spain.

There are two main classes of racing, viz., the long distance race, in which high speed and reliability are the chief points to be considered; and the short races, in which the interest is concentrated on a close finish. The former type is more general on the Continent, and in this case road racing is frequently combined with track racing. However, it is interesting to the general public only in the form of international competitions and when comparison is being made between well known types of machine; and on the whole, the short race is the more popular, particularly when handicaps are arranged in order to result in a close finish.

In form, a racing track is usually annular, the bends being banked, steeply at the outside edge and more gradually towards the inner edge of the track. This permits of the curves being negotiated at high speeds without the risk of skidding or overturning. At Brooklands the banking is designed so that a car travelling in the middle can round a bend at 60 m.p.h. without steering; at the top, or outside, of the bends speeds of over 100 m.p.h. are permissible without steering. The Montlhéry and San Sebastian tracks are more steeply banked than that at Brooklands, and hence higher speeds are attained, the highest speed records being established at Montlhéry. The Monza track is not as steeply banked as Brooklands, and in Italy the interest is centred on road racing, as is the case in Germany.

The advantage of road racing is that it shows up acceleration and braking efficiency, as well as pure engine reliability. On this account there are private road sections connected with the Monza

and Montlhèry tracks. At Brooklands, road races have been simulated by the placing on the track of obstructions.

Whereas, at most places, speed, irrespective of the size of the machine, alone has been considered, at Brooklands class racing has always been strongly encouraged. The cars are divided into various classes, originally according to the cylinder bore, but now according to the cylinder capacity. In 1925, the International Association adopted this policy. It is of interest to note that at Brooklands in 1907, when motoring was in its infancy, Edge, in a Napier, covered 70·07 m. in one hour, and 20 years later, Marchant, in a Voisin, covered 128·35 m. in the same time.

MOTOR-SHIP: *see* SHIPBUILDING.

MOTOR TRANSPORT, COMMERCIAL. The following article deals with the economics of commercial motor transport, with special reference to Great Britain. For a complete discussion of this subject, including engineering design and operation in the United States, *see* MOTOR VEHICLES, COMMERCIAL.

Commercial motor vehicles may be divided broadly into two groups, namely, vehicles for the transportation of goods and passenger vehicles. Dealing first with passenger vehicles, irrespective of the carrying capacity of the vehicles, all the vehicles licensed for the purpose of carrying passengers are known as "hackney carriages." The first motor vehicles of this description to ply for hire in England were motor buses and cabs. Neither class developed very rapidly. The chassis of the early days was not sufficiently strong to stand up to the exacting conditions of regular passenger services and the expenses of running and maintenance were greater than the revenue which was derived by way of fares. Up till about the year 1910 the balance sheets of the various companies showed anything but promising results. Only those with large financial resources were able to survive the transition stages. Until the beginning of the century there had been no experience in this form of traffic to guide either management or design. Until 1914, though the number of hackney carriages was increasing steadily, they were both crude and uncomfortable.

The public service passenger vehicle became an essential in the life of Great Britain about the year 1920. Until then, War Department vehicles were being sold at exceedingly low prices and thousands were converted into passenger vehicles—a purpose for which they were entirely unsuited. Thus it was that though the motor hackney was rapidly replacing the horse drawn hackney, the radius it served round its centre of operation was not greatly in excess of the practical horse radius.

About this time (1920) there were introduced from the United States, light, fast pneumatic-tyred passenger vehicles designed to carry from 14 to 20 passengers with a degree of comfort superior to anything previously experienced and with this example before them British manufacturers almost immediately changed their policy, beginning to manufacture special passenger chassis instead of chassis to serve for the transport of either passengers or goods. With the introduction of such chassis, longer services became practical propositions, until, in 1928, there are very few villages, having reasonable road access, not served with regular passenger services, varying, of course, in degrees of quality and frequency. Thus the number of hackneys alone increased from 31,899 in 1911 to 95,752 in 1927.

On Jan. 1, 1927, the tax on passenger vehicles was considerably increased, which had the effect of checking the growth, but, on the other hand, the improvement of both vehicles and roads had the effect of increasing the earning power of such vehicles, a result furthered by the steady increase in the number of villages and districts remote from railway services which acquired a residential character, the residents being able to rely upon the organized public passenger services to take them either to and from the nearest railway station or direct to their places of business. Long distance motor services have also become established, as for instance between London and Bristol and Exeter; London and Liverpool; London and Newcastle-on-Tyne; or in other cases connecting the more important provincial centres. The vehicles used on these long distance services carry from 20 to 25 passengers in the utmost comfort upon pneumatic tyres and can average speeds of from 20 to 30 miles per hour.

Motor Transport of Goods.—The development of motor traffic for the transportation of goods has been somewhat different from that of passenger transportation, in that the heavier loads were the earlier to show an economic advantage. In this respect the steam wagon led the van. On selected routes and, given the requisite amount of freight, one steam wagon of five tons carrying capacity, could, and did, replace as many as twenty horses. On the other hand, for local delivery work, involving a considerable number of calls, the motor, for many years, showed no advantage in the matter of cost, as compared with horse transportation.

But, notwithstanding the somewhat heavier cost of motor vehicles for goods transport, it was soon appreciated that it had an advertisement value to the tradesman and that larger areas could be served than would otherwise have been possible without the aid of branch depots. The brewing and milling trades were the first to adopt the new transport, as they had continuity of employment and distribution over wide areas, which at the same time did not involve a large number of deliveries. In the initial stages the heavy motors replaced horse transport only; but generally, as their construction and working became better understood, they encroached on what the railways had hitherto regarded as their unassailable monopoly.

Until the year 1907, commercial motor transport was almost entirely effected by the agency of the steam wagon. The internal-combustion-engined vehicle had made some progress for passenger carrying, but, for the transport of heavy loads, it was at first somewhat unreliable as well as expensive in the matter of maintenance. The turn of the tide may be said to have dated from the Royal Automobile Club trials, held in 1907. In these trials close on one hundred vehicles took part. The trials were by no means severe and a fair percentage of vehicles got through satisfactorily. In consequence a moderate demand resulted for goods carrying vehicles of the heavy type. Apart from steam wagons, those vehicles which acquitted themselves creditably, were of from 20 cwt. to 25 cwt. capacity. Lighter vehicles did not do so well and so, for some few years, they were not regarded favourably by the retail tradesman, for whose service they were primarily intended. But the seed was sown and in due course the number of converts to the newer kind of transport steadily increased. The tradesman, whether wholesale, retail or manufacturing, found that from the advertising point of view alone the more enterprising policy was a sound one. As he, as well as the vehicle manufacturers, came to understand the requirements of the new kind of transport better, the radius of action increased and so though the actual costs of motor transport were undoubtedly heavy, comparatively considered, yet the increase in business resulting more than justified the extra cost.

Motor transport, however, is not an easy business to make successful in itself. The rates chargeable for carriage have been determined, on the one hand, by the rates charged by rail and on the other hand, by what would be the cost to a firm owning its own motors. At the same time the carrying contractor's chances of custom are limited, as they depend upon the patronage of firms either not having sufficient work to justify the purchase of their own vehicles or who hire only in cases of emergency. Organized parcels delivery and specialized transport come under a different category, but even their success depends upon the most skilful organization and management.

Hence commercial motor transport is largely in the hands of firms transporting their own goods, and in these cases there is certainly no question as to its economic advantages. It is indeed hardly going too far to say that in the case of many such firms their success is due mainly to the motor vehicle. This applies, more particularly, to the food catering industry, to the furnishing trades, and in relation to market garden produce having to be conveyed from centres near large towns. Whether the railways if they undertake road goods transport on a large scale will be more successful than individual firms remains to be seen.

Economic Radius.—Experience seems to show that, for goods transport by motor, economic efficiency begins at a radius of

about 1½ miles from the central depot. Within this radius horse delivery or electrical vehicles are the cheaper. The maximum economic radius of action on the other hand is not nearly so easily defined depending as it does on tonnage and rates obtainable. Long distance journeys are becoming more usual, but the majority of journeys are those permitting the vehicle to return to its depot each evening. This, provided there are no intermediate deliveries to be made, permits a daily run of about 150 miles. The number of commercial motor vehicles in Great Britain increased from 25,000 in 1911 to 283,000 in 1927, these figures being exclusive of road locomotives and tractors, the total number of which was, in 1927, 4,759.

Running Costs of Motor Vehicles.—The tables below give the approximate running costs of motor vehicles. The following is a brief explanation:—

(1) *Standing Charges.*—The items included under this heading are those which are incurred whether the vehicles are in use or not. Drivers' wages are included. Depreciation is estimated at 20% per annum.

(2) *Running Costs.*—These are the costs incurred whilst the vehicle is actually in motion. A vehicle on local delivery work costs more to run than one engaged on a clear out-and-home run.

(3) *Cost per Journey.*—All owners should know how many days per annum they may expect their vehicles to work; so, by dividing the annual standing charges by the estimated number of working days per annum, the daily standing charges are easily ascertained. Next, by multiplying the running costs per mile by the number of miles representing the journey and adding the resultant to the daily standing charge the cost per journey is readily arrived at.

MOTOR TRANSPORT, MILITARY. Transport by motor vehicles has profoundly modified the art of war. The use of it enables a commander, despite the unwieldiness of modern armies, to achieve surprise effects which give him victory. In the following account, illustrated by practical examples taken from the use of motor vehicles during the operations of the Allied Armies on the French front, there will be discussed the general principles underlying (1) transport of troops, (2) transport of *matériel* and (3) intensive traffic on roads.

I. TRANSPORT OF TROOPS

The Vehicle.—Troops have sometimes been carried in ordinary touring cars. During the battle of the Marne (Sept. 9, 1914), at the moment when the French Army of Gen. Maunoury was massing outside Paris, there were grouped together all available taxicabs to take direct to the front half the infantry of a division which, arriving by rail from the Vosges, was detraining in the stations of the northern suburbs of Paris. This method can only be employed in exceptional cases, because the car or taxicab has so small a carrying power, requiring one driver for every three or four combatants carried, while such vehicles for the most part differ in speed. On the other hand, such motor vehicles as are designed to convey a larger number of passengers in peacetime, *e.g.*, motor-omnibuses or *chars-à-bancs*, are eminently serviceable. Another vehicle is the common motor-lorry (or truck, as Americans call it). It is necessary to adapt it, *i.e.*, to place in it movable benches, which can be very rapidly installed when it is necessary to carry men, and can be removed without difficulty when it is necessary to carry *matériel*. A lorry, according to its capacity, can carry from 16 to 25 men with their arms and equipment. During the World War not only were units of infantry transported but also artillery formations; likewise, in some exceptional cases, cavalry with their horses. When horses are to be carried the body of the lorry must be as large and the bottom as low as possible, to make the loading more easy, and the ceiling must be high enough to prevent the horses being injured by striking their heads. The horses may be placed either lengthwise or crosswise. But they should be close to one another, to save them from bumping; and there should be no difficulty of access to their heads, in order that they may eat and drink on the road. These precautions taken, it has been found that horses travel as well by motor-lorry as in a railway wagon.

Organization of Lorries.—Lorries move grouped in formations of varying importance, but two essential conditions must be observed: efficient control and effective maintenance. The basic

unit, the smallest formation to be placed under the orders of an officer, may consist of 15 to 30 vehicles. The officer who commands this unit is the veritable sheep-dog of his troop of lorries; he must himself have a touring car so as to enable him to follow his lorries when they are on the move, and above all when they are formed into a large column. The officer himself should not drive, but be able to keep his attention free and to jump quickly from his car and speak to his drivers. Next above the basic unit, the "section," is placed the "company" or the "group," normally comprising three or four sections. The commander of the group or company is no longer the sheep-dog of his lorries; he is the shepherd. It is he who guides them in their itineraries, places them in billets and allots them to their work. The second point in an organization is to ensure effective maintenance. Automobiles require constant care on a long journey, *e.g.,* 200 kilometres. Some will have breakdowns, some even fall out; and if the workshop is to move with the group, it must be on lorries, and have a stock of tools and spare parts.

As soon as large transport movements have to be carried out, higher control above the group must be organized. To move the infantry of a division in war required 12 groups. Placed in a column on the road, this would make a file 36kilo. in length, a reasonable distance for each group being 3 kilometres. This mass would be formless and incapable of manoeuvring unless vivified by organization. It is a common saying that the action of a commander ought to be limited to directing four immediate subordinates and no more. Experience of large demands on transport during the War shows, however, that six groups could be united under one control, if the commander in charge was supported by a fully qualified staff. Such was the composition of the grouping in the French Army; such or something very near it was the composition of the "Bus Park" of the British Army. The grouping of six groups had a capacity for 6,000 infantry; the automobile service of the French Army comprised 25 groupings in 1918.

Organization of Troop Transports.—Let it be supposed that a grouping is ordered to carry out the transport of 6,000 infantry, to take them up in their billeting area, and to bring them to the field of battle some 100kilo. from billets. To accomplish this mission efficiently the staff must first fix the embarkation-points, *i.e.,* the points at which the infantry will be loaded into lorries. In order that this operation may be carried out quickly loading must take place at a number of points simultaneously; to embark one battalion (1,000 men) into a group (80 lorries) requires from 20 to 30 minutes. When the commander of an automobile grouping has prepared the organization of his embarkation-points, he must come to an agreement with the infantry headquarters concerned as to the time and place of embarkation of each battalion. The work which devolves upon the command of the lorry grouping in the disembarkation of the troops is generally similar to the above; but there is an additional difficulty, caused by uncertainty as to the exact points of disembarkation, which often depend on the military situation at the moment. Nevertheless, the procedure must be arranged as early as possible, in close touch with the higher staff which has to fix the disembarkation zone; and an understanding must be arrived at with headquarters as to the probable alternatives, between which a decision will be made later, when the lorries are quite near to the arrival zone. The itinerary between the two zones must be reconnoitred and marked out. The "route officer," with his own staff, marks the itinerary by posting up placards (and, for night work, hanging lanterns) bearing the distinguishing mark of the grouping and an arrow indicating the direction of the march and the route to take. Further, the commander of a grouping must organize the movement of his service lorries, supply lorries, workshop lorries, etc.

Transport of Complete Divisions.—An interesting example occurs when, together with the infantry of a division, it is necessary to transport all or part of their artillery with its horses. With horse-drawn artillery it may be a very serious matter for a general not to be able to bring up to the battlefield, in support of his infantry, the artillery who are accustomed to manoeuvre with him. It is thus very desirable to be able to transport artillery with horses. The loading of guns and limbers on lorries does not present any special difficulty; it is sufficient to have fixed rules for putting the *matériel* in place, and these are similar to the loading-rules for the same *matériel* on railway wagons.

II. TRANSPORT OF MATÉRIEL

Lorries are not specialized for the transport of *matériel.* The same type is employed as for troops, and therefore the organization is similar. A lorry-group capable of moving a battalion of infantry can alternatively move 100 tons of *matériel.* Experience in the World War has shown that, during the periods of active operations, a division requires an average of 200 tons per day in foodstuffs and ammunition. This is equally true in the case of defensive areas, as at Verdun; in offensive actions of the type of the Somme battles in 1916; or those of July, August and September 1918, on the Marne. Two groups are therefore required for the supply of a division, subject to the distance from the railway being, at farthest, within a radius of 40 kilometres. Four groups are necessary if the division is 70kilo. from a railway. An average of 3 hours must be reckoned for loading at the stations; with allowance for difficulties arising amid intensive operations, 7 or 8 hours are taken up on the journey and 2 hours in unloading. This gives about 13 hours for work, and leaves 11 hours per day for the maintenance of *matériel,* feeding and rest. If the traffic operations are to be continued for a number of days, more than this cannot be demanded of the personnel or of the *matériel* without risking excessive wastage. On the day after a journey with loads the vehicles return empty, and on the day after that they recommence the journey loaded. As 200 tons a day are required for a division there must be a double set of two groups, with a total capacity of 400 tons.

Non-Specialization of Matériel.—At a general mobilization like that at the opening of the World War, the resources available for transport are necessarily limited not only by financial conditions, but by the number of vehicles in existence in the country capable of being requisitioned, and by the maximum production of the manufacturing firms. On the other hand, there is no limit to the requirements in lorries, because no general thinks he has a large enough stock of transport at those critical times when every addition means an increase in his power of manoeuvre. During the 20 days which intervened between May 27 and June 15, 1918, the lorries of the French Army had to transport about 800,000 tons of foodstuffs and munitions, in order to ensure the supplies of those armies which were making headway against the German attack. And yet, during this same period, the French Headquarters Staff had transported by automobile the infantry of 63 divisions. It was necessary also to make numerous evacuations of public records, civil populations, hospitals and engineer parks. This wonderful effort was only possible because in the French Army the principle of non-specialization was adopted. Every lorry was controlled by the motor transport service of the armies, and was utilized by it for any form of transport needed. No vehicle was specially or permanently attached to this or that higher or lower formation. When a higher formation, such as a division, had need of transport, the automobile service arranged the transport, but as soon as it was finished the lorries employed on this service returned and were available for other transport services. In short, the lorry capital never remained unproductive.

The Use and Duties of Depots.—The reasons for avoiding the wastage of lorries apply likewise to avoid wastage of movement. The carrying-out of "detail" transport is the principal cause of low efficiency. In the battle of Verdun, March 1916, the supply of munitions was taken by rail to Bar-le-Duc and to Baudonvilliers. Trains of munitions arrived daily at these two stations to supply the artillery of the 10 divisions deployed around Verdun, some 60kilo. from the stations. If, to supply each of these divisions, there had been allotted a motor formation, which could come to load up at the stations and go as far as the batteries, bringing munitions, the efficiency would have been mediocre and uncertain. An accident at a depot, an interrupted road, an advance or a check at the front, would set back the whole time-table of the formation, and one would have seen them arriving in the station

for loading their lorries in twos and threes in disorder, and at different hours. There can never be efficiency unless there is regularity of movement. It is never possible to have regularity unless the traffic of the back areas, which can be regular, is definitely separated from the traffic of the front areas, which is always uncertain. This separation can be effected by the creation of depôts depending on the lines-of-communication authorities, and supplied by them where the formations from the front areas come to refill exactly as they would refill from the railway if there were stations at these fronts.

III. INTENSIVE TRAFFIC ON THE ROADS

The Route Gardée.—For the organized employment of automobiles on the roads, like that of railway trains, the essential condition is to be master of the road. If all and sundry are permitted to put columns of troops or vehicles on a road, it is useless to attempt to carry out important movements. It is an absolute rule, based on experience, that it is not possible to launch a big transport movement involving several hundreds of lorries without being absolutely certain of the complete freedom of the road during the whole time that the movement will last. Hence the organization of the *routes gardées,* with their personnel of guards and their traffic orders.

A *route gardée* is not necessarily reserved exclusively for automobiles. But in every case there must be a responsible authority, having power to give orders and have them carried out. In the French Army, during the War, this authority was a motor regulating staff (C.R.A.). In the British Army, the control of traffic in France was part of the duties of the Provost Marshal's staff (P.M.). The organization of the route, on a railway model, is based on the block system. The route is divided into a series of districts, each of which is under the direction of a district chief, having assistants for supervision. The district chief is in constant touch by telephone with the neighbouring districts, and with the office of the C.R.A.; he knows all the movements which affect his district, and also keeps a record of all movements which occur there and all the incidents of the traffic. Thus at the office of the C.R.A. it is always known what the state of the traffic is on every *route gardée,* and the necessary arrangements for launching an important movement can be made in a short time.

The length and the importance of the districts on a *route gardée* depend, obviously, on special difficulties to be overcome, *e.g.,* the number of adjacent routes, localities traversed, narrow passages, etc. Between Bar-le-Duc and Verdun there were six "districts" varying in length from 5 to 10 kilometres. It is quite unnecessary to control in this permanent fashion a route over which there is not continuous traffic. Whenever such a road is needed, for the time being, for an intensive transport operation, it is sufficient to occupy it immediately and transform it into a *route gardée*. This requirement leads to the C.R.A. (or any corresponding organization) being given a territorial zone of operation. In each zone it is the immediate business of the C.R.A. concerned to guard any portion of the road over which the transport will be moving. For this purpose the C.R.A. had at its disposal specially organized personnel, which may be fairly accurately designated "mobile districts," and which, being in the habit of operating in this way and supplied with the means of rapid installation, can, in two or three hours, make themselves masters of the traffic on whatever part of the road is entrusted to them.

Maximum Efficiency Over a Road System.—When one is master of "circulation" throughout a given region, one is free to aim at maximum efficiency. Formerly, when the staff proposed to carry masses of troops to a theatre of operations it traced the greatest number of parallel and serviceable roads which led to the zone of action decided on, and there was thrown on each of these roads a column of all arms scientifically echeloned in depth. Thus it was that Napoleon moved from the Rhine to the Main in 1805; thus, also, Moltke moved from the Sarre to the Moselle in 1870. When this system is applied to present-day conditions the efficiency of the road system is low, because the increase of speed due to the automobile is not turned to account. All modern armies have motor tractor-drawn heavy and light artillery and possess the means of transporting the bulk of their infantry by motor-lorry. In consequence, in co-ordination with the movements made by railway, the movements by road ought to be organized in the form of special itineraries, on each of which move columns of elements that are homogeneous from the point of view of speed. Thus combination of movements can be worked out in which much time is saved, as compared with the old methods.

The existence of regulating commissions in charge of zones of movement, and masters of the traffic, considerably eased the French problem. But the regulating commissions must have control not only of automobile traffic, but of all traffic; in their zones no movements must occur without their having received notice and taken the necessary measures to facilitate the execution of the movements in question. They must be able to arrest all false movements in good time. And they must be in close touch, so as to form a complete network, covering the whole area over which it may be necessary to move any column. It was by the functioning of an organization of this nature that the French Army was able to make its concentrations of considerable numbers of troops at very short notice in March, May and July 1918.

Strategic Transport by Road.—As the automobile has brought on the road again the tourist who had deserted it since the middle of the 19th century, so transport by motor lorry has brought into use again strategic movements by road. And, for the production of surprise effect, by adding the roads to the railways, it has been possible to put to full use all available means of communication. The air alone has not been utilized; but in the future it may be employed for the quick transport of combatants.

Combined Use of Railway and Motors.—In the majority of cases, use is made of railways and roads in combination. The end to be attained is always a rapid move of powerful forces; the staff should therefore make use simultaneously, and as efficiently as possible, of every means of transport which it possesses. One must never lose sight of the fact that the efficiency of the railway is much superior to that of the road; a train of 50 wagons is equivalent to 150 lorries. At a speed of 30kilo. an hour, and with four departures an hour, one has four trains in a length of 30kilo., or the equivalent of 600 lorries. We have seen that 600 lorries form on the road a length of 20 to 25 kilometres. Railway and road have, therefore, very nearly the same output. But the lorries, going 15kilo. an hour are only half as quick. Further, at the end of 100kilo. it is necessary for the lorries to stop in order to rest the drivers, for, save in exceptional cases, relief crews are out of the question. The weak point in transport by rail really lies in the necessity of having stations for embarking and for disembarking. Save in quite exceptional cases it is an absolute technical necessity to load and unload in stations, and, even so, only in those where there are sidings sufficient to take the military trains so as to leave free the main line during the times of embarking and disembarking. Without this precaution all the traffic will be blocked. Further, when it is a question of loading *matériel* it is necessary to place it on the platforms. While special platforms or docks are indispensable on the railway, it is always easy, on the road, to find or organize quickly loading-places for lorries.

Big movements by railway can be made only from a zone A to a zone B, if the two zones A and B are equally rich in loading-places. But—apart from those points which come into the initial concentration scheme, and on which, therefore, work can be done in peace—it is impossible to ensure, in the large movements which military operations may necessitate at any given moment, that the beginning and the end of rail transport shall take place in zones that are rich in loading-places. On the other hand, it is generally possible to find, within a radius of 50 to 100kilo. in the zones A and B under consideration, one or more regions rich in loading-places. The normal combination consists, therefore, in utilizing motor transport to prolong railway transport, and to carry the troops or *matériel* (1) from their stationary zone to the places of embarkation, and (2) from their places of disembarkation to the zone of operations. The relatively short movements (50 to 100 kilo.) it requires are those in which the efficiency of the lorry is at its greatest. And between the two zones of loading thus actually used, the efficiency of the railway will equally be a maximum.

Naturally, other combinations are also practicable; for example, that by which, on Nov. 20–21, 1917, three French divisions were to be carried from Meaux and Château-Thierry to Péronne; the infantry, with their machine-guns and cooking-carts, being conveyed in motor lorries, and the artillery by train. The object of these movements, very quickly ordered on Nov. 19, was to reinforce the successful British attack in front of Cambrai with the first use of tanks in mass. While the embarkation of the artillery was proceeding at railway stations in proximity to the divisional billets on the Marne, the C.R.A. of Meaux and Château-Thierry loaded up on 3,000 lorries the infantry, etc., of the three divisions.

There are many details which complicate considerably the task of the transport officials; such as the question of food supply for the troops during their transportation and at their disembarkation, and the question of moving troops simultaneously with the building-up of the munitions dumps which they will require. One last remark should be made: transportation by automobile and by railway, which, we have seen, supplement one another happily in regard to distance, is equally satisfactory in regard to time. Large movements by railway require concentration of *matériel*, often difficult to achieve; and, in the case of moves decided on in a hurry, the possibility of motor transport on a large scale assumes very great importance, since it takes four or five days for the railway to show its full powers.

Conclusion.—The experience of the War shows the rôle which transport by motors is called upon to sustain becoming more and more important. The Allied Armies, together, placed on the French front about 20,000 motor vehicles in October 1914; four years later the number exceeded 200,000. At the time of the Armistice the inter-Allied transport reserve, the creation of which had just been decided on, was of a size to transport simultaneously 10 divisions of infantry complete, with all their means of fighting, machine-guns and artillery included. This was a fighting mass of more than 100,000 men, which the Higher Command was able to pick up at short notice and carry at the speed of 100kilo. a day to any point where it was required. As regards the transport of *matériel* at the end of the War, it had become possible—independently of resources just mentioned—to keep supplied with food and munitions 40 divisions at a distance of 100kilo. from the railways.

CROSS-COUNTRY TRANSPORT

Until comparatively recently the evolution of the cross-country mechanical vehicle has depended in the main on the initiative of the military authorities, though some agricultural tractors were developed before the World War, notably in the United States. American tractors were in fact adopted in the war as the standard tractor for heavy artillery in the British Army. At present, in many parts of the world where roads are poor or non-existent, and colonization and development are proceeding, there is an increasing realization of the value of cross-country mechanical transport vehicles. This is leading to an increasing demand for them, and will ultimately simplify the military problem, in that types of vehicles better suited to military employment will come into greater commercial production. Certain features of recent technical developments leading to increased cross-country ability, on the part of load-carrying vehicles, are not inconsistent with improved performance on good roads.

"Wheel" and "Track" Vehicles.—The earliest serious attempts to use self-propelled vehicles in war occurred during the South African War. In order to overcome natural obstacles of the ground, rough surfaces and boulders on the one hand, and softness of surface or sub-soil on the other, very large wheels were employed, as great as seven feet in diameter and two feet in tyre width, each wheel weighing as much as two tons. Some early lorries were also equipped with armour and armament. It was found that owing to their great weight, none of these machines were of much use except on hard smooth surfaces, and on the most moderate gradients.

After that war efforts were directed both in England and in the United States to obtain the beneficial effect of the very large wheel without its disadvantages. These efforts led to the development of what is now known as the "track," or "track-laying" machine. The idea that a vehicle should run on wheels on an endless road or track which it laid for itself was not new, the first invention of the kind, as far as can be ascertained, being that of R. L. Edgeworth in 1770. There were many ingenious inventions in the first half of the 19th century—the most practical results being achieved by James Boydell. His patent of 1846 and the tractor he produced are described with many others in *The Economy of Steam on Common Roads*, by C. F. T. Young, C.E. (1860).

Between 1903 and 1914 many important developments took place of which an interesting account may be found in two papers by L. A. Legros, originally published in *Engineering*. Some notable landmarks were, in the United States the Lombard track (1904), the Holt track known as the "Caterpillar" (1905), the Strait climbing chain-track (1912), in Great Britain the Diplock and "Pedrail," and the Roberts track (1904–08). Appreciation of the track-laying principle led to a considerable commercial adoption in the United States, where the need for powerful haulage in connection with lumbering, etc., was keenly felt. Internal-combustion engines were used on almost all of the vehicles incorporating these tracks. In England efforts were practically confined to developing machines suitable for military use, although both Roberts and Diplock proposed schemes for transporting heavy loads across country. (*See* Pl. I., 1, 2.)

Early in the World War track-laying machines driven by internal-combustion engines were adopted, firstly as tractors for the haulage of heavy guns, and secondly as a means of transporting into battle both men and their weapons under cover of armour protection. The latter type of machine, the tank (*q.v.*), was perhaps the most startling production of the war, and had a profound effect both on the issue of the campaign, and on the subsequent evolution of machines for cross-country travel.

Physical Factors Affecting Cross-country Travel.—A brief review of factors and conditions to be considered in connection with the design and performance of both wheeled and track vehicles intended for cross-country work follows:

Condition of ground. The three main factors affecting the degree of ease with which a load may be moved over the ground are: (*a*) the contour; (*b*) the hardness or softness; and (*c*) the nature of the material composing the ground—*i.e.*, whether it is slippery or not on the surface, and whether it is strongly bound together within, or will disintegrate or slide within itself when a force is applied to it acting in a plane parallel to the surface.

The tractive effort of a self-propelled vehicle is the force it exerts, through the medium of its driving wheels or track, against the ground, and by virtue of which it is able to progress.

Adhesion. Two things are necessary in order that the tractive effort exerted by wheel or track may make the vehicle progress:—(*a*) there must be sufficient grip between the wheel or track and the ground to prevent slip between them; (*b*) the ground itself must be firm enough to resist the tractive effort exerted upon it without sliding or disintegrating within itself. The greater the area of ground upon which a given tractive effort is exerted the less the tendency of the ground to fail.

Rolling Resistance. The rolling resistance of a vehicle is measured by the tractive effort required to keep it moving at constant speed on the level. It is thus a measure of resistance to movement due to the nature and inequalities of the ground and to the internal mechanical friction of the transmission gear, wheel bearings, track mechanism, etc. As far as the effect of the ground on rolling resistance is concerned it will be well to consider the behaviour of a wheel under different ground conditions. The amount by which a wheel sinks into the ground has a profound effect on rolling resistance. With a hard wheel rolling on a smooth and hard surface, the resistance is very small. But if the ground be soft, and the wheel sinks into it, the resistance may reach very high figures such as 600lb. for every ton of wheel weight. When a wheel sinks into soft ground it has, in order to advance, either

to push the ground away in front of it, or else to climb the slope it has made in front of itself by the act of sinking. A practical maximum of ground resistance is reached for any particular vehicle when either the greatest tractive effort of which the vehicle is capable or the adhesion between driving wheel and ground is insufficient to overcome the rolling resistance, and progression ceases. If there is a gradient as well, then a less degree of rolling resistance will suffice to arrest progress.

Thus the primary endeavour in designing a vehicle for cross-country work where soft and weak or friable ground may have to be traversed, is to secure a large area of contact between driving wheels or tracks and the ground. This has the effect of (*a*) reducing pressure between wheel and ground and thereby reducing sinkage and resistance to progression; (*b*) enabling weak ground to sustain a greater tractive effort, because the effort is spread over more ground. It is clear, therefore, that, if a vehicle has driving wheels which are large enough in diameter and wide enough for a given gross weight, then it can negotiate almost any obstacle. Unfortunately, considerations of weight, structure, visibility, etc., limit the size of wheel which is practicable. Cross-country vehicles are tending, therefore, to develop along two main lines:—(*a*) The incorporation of an increased number of driving wheels, of moderate diameter, together with the equipment of all wheels, whether idle or driving, with wide tyres having a flexible periphery, as in the case of soft pneumatic tyres. (*b*) The incorporation of endless tracks which provide a large area of ground contact and a firm road on which the wheels carrying the vehicle can run.

The Development of Wheeled Vehicles for Load-carrying.—A vast number of lorries (trucks) was used by the various belligerents in the World War. In the main, these lorries were heavy and of one type, having four wheels, of which the two rearmost were the drivers, the wheels being shod with tyres of solid india-rubber and in some cases even with steel tyres. The vehicles were themselves heavy and carried a useful load of from three to five tons. Thus they exerted a high pressure on the ground—as great as 180 lb.sq.inch. As a result, these lorries were found to be quite unsuitable for use on any surfaces but fair hard roads. They were allocated, in the main, to the more rearward transport services, but were enabled, owing to the multiplicity of the roads already existing in Western Europe, and the most strenuous efforts and lavish expenditure of man power on road maintenance and construction, to execute intensive services well forward in the battle zones, such as the entire transport of ammunition and supplies to the heavy artillery.

Certain lorries, all four wheels of which were driving wheels, had been produced before the war. Although these machines also had narrow and hard tyres it was clear that the distribution of the drive vastly increased the power of traction and the ability to travel across country. Such four-wheeled drive machines were used extensively for pulling guns. In Italy, Salonika, Africa and the Near East it was found that lighter vehicles, carrying light loads, and shod with pneumatic tyres could maintain services on poor mountain roads, and on roadless country and desert, where the heavier solid-tyred vehicles were quite unable to operate. Vehicles of this type were the Ford (7 cwt.), Fiat (1 ton), and Crossley (15 cwt).

The British War Office took very definite steps to profit by this lesson. In 1923 a specification was produced for a light lorry to carry a useful load of 1½ tons, having a high power/weight ratio; it was shod with large size pneumatic tyres on its four wheels, the two rearmost of which were driving wheels. A cash subsidy was offered to owners of approved vehicles, and a substantial reserve was built up in a few years. These army-type lorries exercised a considerable influence on subsequent commercial developments—particularly with regard to the adoption of the pneumatic tyre for load-carrying lorries. The improved cross-country performance of this type of lorry led to a decision to mechanize the supply, transport and baggage services of the division. There remained the problem of the mechanization of first line transport.

Efforts were next directed to the development of a type of vehicle having the following main features:—(1) Lower intensity of pressure on the ground; (2) Increased useful load capacity; (3) High speed; (4) Higher ratio of tractive effort to gross weight; (5) Great powers of adhesion to make use of the tractive effort available; (6) Increased flexibility in construction, giving ability to traverse rough ground without setting up undue stresses in the chassis; (7) Reasonable first cost; (8) Economy in running and maintenance; (9) Attractiveness to the commercial user at home, as well as in the dominions and colonies; (10) Ease of handling; (11) Ability to cross country without making the ground traversed more difficult for following vehicles. It was clear that the solution lay in providing more driving wheels per vehicle. Experiments with vehicles having three axles and four driving wheels had been made in the United States and in France, culminating in the successful trans-Saharan journeys of the light Renault six-wheelers in 1923–24. In the light of prolonged tests it became clear that such six-wheeled vehicles, in addition to ability to travel across country, were also admirable road vehicles, being fast, safe, smooth running, and economical, and as reliable as four-wheelers. Until quite recently it has, not without reason, become the custom to expect that any advance in the power of vehicles to move across country could only be obtained at the cost of a proportional decrease in efficiency for use on good roads. The importance of the unique quality of the modern multi-wheeled vehicle which causes it to be effective and economical in operation on both good and bad "going" is self-evident. Subsequent steps taken by the British War Office have resulted in the six-wheeled vehicle being produced by seven or eight of the leading manufacturers of British commercial vehicles, and in its adoption on a considerable scale, in Government and commercial service both at home and in the dominions and colonies where the characteristics of this type of machine are proving of particular value. Six-wheeled vehicles of the same general type are also in standard production in the United States, France, Germany, Belgium and Czechoslovakia.

There are several methods of suspension of the four driving wheels under the load. The aim is to ensure that, within certain limits, the driving wheels are free to exert their tractive effort uniformly, and to follow the rise and fall of the ground contour without disturbing unduly the distribution of weight over the wheels, and whilst causing a minimum of movement and distortion of the main frame of the vehicle.

Twin pneumatic tyres having special treads designed to secure the maximum adhesion on muddy ground, may be used in conjunction with an easily detachable "overall non-skid chain" in order to give greater supporting area and adhesion on soft, weak and slippery ground. (*See* Plate I., 3, 6.)

The great tractive effort which can usefully be employed on such a vehicle calls for abnormally great reduction in the lower gears, while small reductions are required in the higher gears to enable high speeds to be employed on good surfaces. A wide range of gears may be obtained by the introduction of a subsidiary two speed-gear behind the main three- or four-speed gearbox. The main gearbox and power unit may then be of quite normal pattern as used in normal four-wheeled lorries. The good performance of these six-wheeled lorries across country, coupled with the fact that they are cheap to make and to operate, and therefore attractive to commercial users, makes possible the mechanization of the first line transport of fighting units. Because the vehicles are fast and can reach their units quickly without long occupation of road space, and can, when necessary, divert from the road, it is found practicable to relieve the infantryman and cavalryman on the march of some of the weight of equipment and kit which they have hitherto had to carry.

Since the South African War, when steam traction engines were used to haul trucks, various attempts have been made to produce four-wheeled internal-combustion vehicles, having two large rear driving wheels tyred either with steel or solid rubber, which should be capable of operating across country. The Italian Fiat Model 20 tractor used for artillery haulage during the World War may be cited as a typical example of this class of vehicle. Other makes used during the World War were the Foster-Daimler (Britain), the Lanz and the Benz (Germany).

1. Hornsby heavy chain-track tractor, paraffin engine, 1904–8. The shape of the track in contact with the ground resembles that of the rim of a wheel of very great diameter. This machine was a fore-runner of the Tank and other modern whole-track vehicles
2. Hornsby light chain-track tractor, petrol engine, 1907. The inventor, Mr. Roberts, is in the foreground
3. Modern 6 wheeled lorry. The four wheels at the back all drive and are fitted with pneumatic tyres. They are also free, within limits, to follow the contour of uneven ground without causing any distortion of springs or chassis frame
4. Experimental motor cycle incorporating two articulated driving wheels. Here again the object in view is to improve driving adhesion by getting a greater driving area in contact with the ground. The band fitted to run over the two driving wheels gives extra support on very soft ground, and is easily detachable
5. Typical heavy petrol tractor, 1914–18. It has large driving wheels with steel tyres, and adjustable spuds to improve the driving grip on soft ground
6. Modern 6-wheel-drive tractor, having 6-cylinder petrol engine, six forward gears, pneumatic tyres, detachable driving chains, and a power-driven winding gear. Such a vehicle has a greater driving area on the ground and is much lighter than a tractor as in fig. 5 employing only two large driving wheels

BY COURTESY OF (1) "MOTOR TRANSPORT," (2) L. A. LEGROS, M. I. MECH. E., FROM "TRACTION ACROSS COUNTRY" ("THE ENGINEER"—1924)

1. Modern six-wheeled motor car with four driving wheels, designed for travel across soft and rough country. The "overall" chain shown in use is detachable, and is only used to give increased support

3. Half track lorry. The track is a rubber and canvas band and is driven, by friction, by the rearmost wheel. On certain vehicles of similar type the track band is positively driven, engaging with teeth formed on the leading wheel of the track assembly

In general, this type of vehicle is a failure for cross-country work, as it is impossible to make the wheel large, wide and light enough to avoid sinkage and loss of adhesion. The most elaborate devices in the form of adjustable or detachable spuds, girdles, and diggers have been employed to prevent slippage of the driving wheels. Such devices often defeat their own object, and may have the effect of causing the driving wheels to "dig in" more swiftly on soft ground. At the best, they cause such severe damage to the ground traversed as to destroy it, and thus deny passage to following vehicles. Furthermore, such girdles, spuds, or diggers can only be used at very low speeds. (*See* Plate I., 5.)

Reference has already been made to the advantage of driving on all four wheels of a four-wheeled vehicle. As described in his book, *A new System of Heavy Goods Transport on Common Roads,* B. J. Diplock patented, in 1893, a design for a four-wheel-drive steam tractor. Many tractors of this type, and driven by internal-combustion engines, were developed during the World War, examples being the F.W.D. (United States) as used for the heavy artillery of the British army in the war, the Latil and the Panhard (France), the Mercédès-Daimler and Erhardt (Germany). The most successful was, perhaps, the Mercédès-Daimler, on account of its larger wheels and its excellent general proportions and design. These vehicles were all successful in varying degrees, but could not be said to be true cross-country machines. Some had solid rubber and others steel wheels, and several were equipped with powerful engine-driven winding gears with which they could extricate themselves when bogged on soft ground. All of them were heavy

After the war the British War Office tested two-wheel-drive and four-wheel-drive tractors of British, American, French, German and Italian origin, but none of them were found truly effective for cross-country work. It was considered, however, that a lighter four-wheel-drive tractor having the largest size of pneumatic tyres, and incorporating a wide range of gears, giving high road speeds, and a big tractive effort at low vehicle speed, as well as a powerful engine-driven winding gear, might be of service. It was estimated that it would haul 10 tons on average roads and four to six tons across country where the conditions were not too severe. A specification was prepared which resulted in the production of the Thornycroft so-called "Hathi" (Elephant) tractor. It has proved to be a fast, powerful and economical tractor, effective for cross-country conditions of many kinds. But when soft sand or slippery and boggy ground are met even this vehicle, with its moderate axle weight and large pneumatic tyres, is found to sink in unduly and lose adhesion. As a result of this experience such a tractor has been converted into a six-wheeler by the addition of a third driving axle. Several manufacturers in Great Britain are giving attention to the production of six-wheel-drive machines. (*See* Plate I., 6.)

A review of modern wheel vehicles would be incomplete without reference to the Pavesi articulated machine, produced in Italy. Reference has already been made to the importance of articulation on cross-country vehicles—that is, the property by virtue of which the wheels are free to follow the contour of the ground without undue disturbance of wheel-loads and without causing undue movement and twisting of the vehicle as a whole. The Pavesi tractor is almost completely articulated. The vehicle is made in two rigid portions joined together by a "wasp waist." Within certain limits the two portions of the vehicle are free to pivot both in the horizontal plane in order to steer, and about the longitudinal axis of the vehicle, in order to enable the wheels to rise and fall relatively to each other and so follow, freely, the contour of the ground. It is easy to see the great degree of articulation provided. All four wheels, which are of large size, are "drivers," the power being taken from the engine and gear-box on the front half of the machine, through a universally jointed propeller shaft to the rear half of the vehicle. The vehicle in its present state of development is not adapted for fast work on the road; it is not a dual-purpose vehicle. (*See* Plate II., 2.)

Motor-cycles are used to a considerable extent in military service. The conventional motor-cycle having two wheels, of which only one is driving, and having little ground clearance, is not useful across country. It suffers from lack of adhesion to drive, sinkage on soft ground, and fouling at the "belly" on relatively small obstacles. A machine is being developed experimentally in an endeavour to overcome these disadvantages. The machine has tyres of large section and low air pressure, the two small wheels are both "drivers" and are mounted in a manner to provide some articulation, and enable them to follow the contour of the ground. (*See* Plate I., 4.)

"Track" Vehicles.—The necessity for great ground area contact both for supporting and driving a cross-country vehicle has been noted. Early attempts to achieve this end by means of very large wheels led to the development of the endless track, or track-laying machine. It became clear, during the World War, that only by utilizing long and wide tracks was it possible to transport the great weight of the armoured fighting tank. By the use of tracks the average pressure on the ground was kept low, *e.g.,* 12 lb. sq. inch. The shape of the effective portion of the track protected other parts of the tank from coming into contact with the ground. The tracks also provided the adhesion necessary to enable a great tractive effort to be employed. Tracks are of the following kinds:—

(*a*) *Metal tracks* (articulating). These consist of a series of rigid metal shoe-and-link units jointed together. The drive is by a sprocket which meshes with teeth on the inside of the track. The track usually presents an almost continuous surface to the ground, and therefore the intensity of pressure exerted may be made very low. In order to make the track bear uniformly on the ground, and in order to "spring" the vehicle, its weight is supported by a series of small wheels running on the inside of the track, and these accommodate themselves to the contour of the track lying on the ground by means of spring and/or compensating lever mechanism introduced between them and the chassis. The tracks are also sometimes permitted some degree of articulation in the horizontal plane to facilitate, or achieve, steering by enabling the track to lay a curved road on the ground. But the life of such metal tracks is short, especially when driven at high speeds and on hard roads. (*See* Plate II., 3.)

(*b*) *Flexible band tracks.* These are made of canvas and rubber, sometimes with metal reinforcement. The drive is by friction, the track being formed with a Vee-shaped portion which engages with a Vee-groove on the driving wheel. The suspension of the vehicle on the track has been described above. Such tracks are quieter than the metal track.

Adjustment of the centres of the main track wheels must be made simple, as it is not easy to maintain correct tension to ensure driving grip between the pulley and the track band. The life of these tracks also is not long, and the mechanism is somewhat costly.

In order to obviate slip between driving wheel and band, experiments are in hand to try and secure positive instead of friction drive. (*See* Plate II., 4.)

(*c*) *Girder track* (*or truss wheel*). This is a metal track, but the joints between adjacent shoe units are formed so as to limit the maximum radius to which the track will conform.

The pivoting inwards is not limited and the track runs around two wheels only.

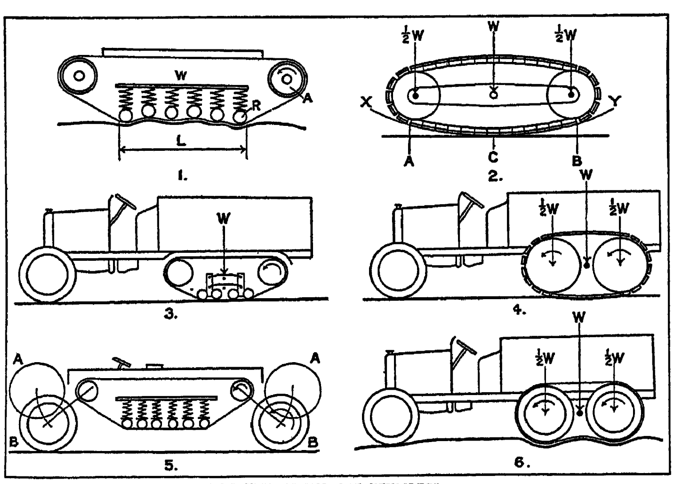
The lower portion of the track, being prevented from accommodating itself to the contour of the ground, forms a short arc of a circle of very great diameter, providing the effective low rolling resistance of a very large wheel. It is difficult to make the track strong enough to support, on hard ground, the weight of the load on each end of what is, in effect, a rigid girder.

(*d*) *W.D. type overall chain.* This device is a compromise between the track and the ordinary non-skid chain used on wheeled vehicles. It has been developed to enable the six-wheeler to cope with very soft and slippery ground. The chain is used over an ordinary twin pneumatic tyre equipment, and the drive is obtained only by virtue of the weight of the driving wheels on the shoes. Vehicles can run at 15 to 20 miles per hour with the chains fitted, and the chains make little noise. The shoes can be of small or large area according to the nature and supporting power of the ground to be negotiated. The chains are compara-

tively light and cheap to produce or replace. The pair of chains can be fitted to a vehicle in a few minutes. The diagrams in fig. 1 show:

(1) Whole-track vehicle—such as heavy fighting machines, gun tractors or carriers, etc.—articulating metal track—weight "W" distributed over small wheels R—drive by sprocket A—usually steering is achieved by relieving the drive on the inside track, and the vehicle slews around pivoting on the length L of the inside track. (For illustrations of whole-track vehicles, *see* TANKS.) (3) Half-track vehicle—having either metal or rubber articulating tracks instead of rear driving wheels. The front steering wheels are usually not driven. (5) Wheel-cum-track—this type is being experimented with by both French and British armies. Means are provided whereby the wheel axles can be raised or lowered—when the wheels are at A the vehicle runs on tracks (metal articulating), when at B the track is off the ground and the vehicle runs on the wheels. (2) Girder-track—the portion of the track from A to B—is a rigid girder due to the locking joints. On hard ground the stresses in the joints when the track is touching at C only, and ½W is applied at A and B are clearly high. A C B is a small arc of the imaginary large wheel X C Y. (4) The possible application of the girder-track to the six-wheeler. (6) Six-wheeler with "overall" chain.

Probable Lines of Development of Military Cross-country Vehicles.—It has been demonstrated, by trials specially arranged to test the relative capabilities of all types of modern vehicles to negotiate difficult conditions of cross-country "going," that:—(*a*) the long whole-track machine is essential for tasks where wide trenches, high banks, and soft bog have to be negotiated without delay, and where great gross moving weight is involved; (*b*) whole-track vehicles are able to tow heavier loads over soft ground than either half-track or wheeled vehicles; (*c*) for carriage of moderate loads there is little to choose between six-wheeled and half-track vehicles in regard to cross-country performance, while the former are at a great advantage on good roads, and in regard to cost of provision and upkeep. It seems probable, therefore, that, until they reach a much higher pitch of mechanical perfection, the use of tracks will be confined



FROM MAJOR C. H. KUHNE, "MILITARY TRANSPORT VEHICLES"

SIX SYSTEMS OF OBTAINING LARGE AREA OF GROUND CONTACT FOR CROSS-COUNTRY VEHICLES

1. Whole track, metal (articulating). 2. Girder track (or truss wheel). 3. Half track, metal or rubber (articulating). 4. Girder track applied to 6-wheeler. 5. Wheel-cum-track. 6. Six-wheeler with overall chain

to the minimum number of special military vehicles considered essential on mobilization, and that dependence must be placed on multi-wheeled vehicles for the great bulk of army transport.

A survey of military transport in various countries indicates certain general lines of development. Tanks or "chars d'assaut," whether large or small, will be whole-track machines. Gun tractors may be whole-track, half-track, or multi-wheel-drive vehicles, according to the weight of gun, nature of task, estimated condition of terrain, and considerations of the economics of provision and upkeep. Armoured cars and first line transport vehicles will probably be six-wheeled vehicles (with at least four wheels driving), or other improved multi-wheeled vehicles. Second and third line transport will be heavier six-wheeled vehicles, if available. If not, lighter pneumatic-tyred four-wheeled vehicles of comparatively small load capacity, and which are in extensive use commercially, may be used in the more forward echelons, and less mobile heavy commercial lorries, of three to six tons load capacity further in rear.

The Problem of Transport in Undeveloped Territories.—There are many territories awaiting development when cheap transport becomes available. In many cases the building of railways is prohibited by physical difficulties or financial considerations or the uncertainty and seasonal nature of the traffic available. Heavy and regular traffic is required to make a railway pay. The need appeared to exist for long-distance feeders to the arterial railways and waterways, approximating to branch railways in reliability and charge per ton of produce carried. In most cases the construction and maintenance of roadways suitable to carry normal motor-vehicle traffic is out of the question. Even if the roadways existed, the cost of carrying produce long distances in detail in ordinary lorries would be prohibitive. Only by moving large unit loads, say, 50, or even 100 tons, on transporters which can travel on dirt tracks without destroying them, could the cost per ton-mile be kept within economic limits. Such a transporter would travel, at moderate speeds only, on endless-track units, if possible consuming fuel of local origin.

The acceptance of the six-wheeler of suitable design is natural, since its cross-country performance is good, especially with the overall chains, which can be easily fitted and carried when not in use. At the same time it is economical and fast on good "going" and as easy to drive and look after as any ordinary car or lorry. There is great need of a flexible wheel or tyre which is unpuncturable, and which will provide a low rolling resistance on soft ground, similar to that provided by very low pressure pneumatic tyres. Tracks will probably be used for the heavier loads, and where very great towing capacity across country is required and no high-speed running is involved.

The big transporting unit may consist of a powerful tractor with articulating metal tracks to give the utmost adhesion, towing a train of large capacity trailers on girder tracks to give the lowest possible rolling resistance. Even though the loads be heavy the track surface can be made great and the pressure on the ground kept low so that the continuous passage of the machine will pack the ground and improve the "going." Thus, it seems probable that the development of transport vehicles for military use and for commercial use in the less highly developed parts of the world will follow similar lines and be mutually interdependent to some extent.

Conclusion.—Those nations in which the military transport authorities work in close collaboration with the civilian manufacturers and users of mechanical vehicles, are the most likely to be in a strong position in regard to mobility on the outbreak of war. Recent developments in wheeled vehicles have shown that the very features which are of advantage for use across country, are, to say the least, not detrimental to the performance of the vehicles on good roads. Thus, transport vehicles suitable for use in war may, by well directed efforts, be brought into use commercially even in countries provided with good roads. For countries having rich, but undeveloped districts, or possessions overseas, the task is simplified. Even in the case of the more special military types of vehicles incorporating tracks, technical development may be hastened by the judicious encouragement, by governments, of the use of heavy goods transporters for opening up undeveloped districts, and of agricultural tractors. The world is crying out for efficient transport—whether roads exist or not; the more the encouragement given, and the greater the production and employment of vehicles, the more effectively equipped will the armies of the world become in regard to the vital quality of mobility. MOTOR VEHICLE INSURANCE. The growth of motor transport during the last 25 years has resulted in a demand for very specialized insurances to protect private and commercial vehicle owners and motor traders. Each have their own particular risks necessitating widely different forms of cover.

The principal feature of any insurance covering the road risk is obviously that relating to liability to third parties, particularly when it is considered that thousands of persons are killed or injured by motor vehicles annually, resulting in the majority of cases in a monetary responsibility on the part of the vehicle owner for law costs incurred in his defence in subsequent proceedings, if not for damages eventually awarded to claimants. A feature of importance of all such third-party insurances is the legal representation of the insured by the insurers at any police-court proceedings or coroner's inquest, though this service does not extend to subsequent criminal proceedings. With few minor exceptions all British motor policies provide an indemnity unlimited in amount as regards the legal liability to third parties for personal injuries, though as regards damage to property of such persons the practice varies. Whilst owners using their cars solely for private and professional purposes may obtain an indemnity unlimited in amount in England, this is always limited as regards vehicles otherwise used to £10,000. Law costs incurred with the insurer's consent are invariably included. Elsewhere the limit of indemnity as regards personal injuries and damage to property must be fixed by the proposer at the outset. On signing a proposal form the proposer warrants the truth of his replies to the questions and his answers constitute the basis of the contract. Whilst most of the questions are designed to obtain the necessary information for rating and for the completion of the policy, others relate to the past experience of the risk.

Private Car Policies.—Both as regards the premiums charged and the cover provided the private motorist receives preferential treatment. The third-party cover has already been discussed and in addition the insured is indemnified, within the limits of the sum insured, for loss of or damage to the car caused by fire, theft or any attempt thereat, any accidental, malicious or wilful damage. Damage to tyres is not covered unless the car itself is also damaged. Mechanical breakdown risks are excluded, but all damage to the car and liability to third parties incurred subsequent to, though the result of, the mechanical breakdown are covered. Policies provide for the cost of removal of a car from the scene of the accident to the nearest competent repairers and the cost of redelivery to the insured.

Privileges confined solely to private car policies, in the form of medical and surgical expenses for all occupants and personal accident benefits for the owner, may be obtained and the British policy permits three months' Continental use in any one year of insurance. Most modern private car policies extend to indemnify the insured in respect of his third-party liability whilst driving other cars and friends of the insured whilst driving the insured car with the owner's general knowledge and consent. On payment of additional premiums the insured may cover special risks such as the loss of rugs, coats and luggage; medical and personal accident benefits for himself and other persons; compensation for loss of use; an indemnity for employer's liability, and mechanical breakdown.

Reductions of premium are allowed if the car is driven only by a named individual (other than a paid driver): if more than one car is insured under the policy; or if the insured bears a first amount of every loss under the damage or all of the sections of the cover. A bonus is allowed if no claim arises during the year of insurance. Private cars are generally rated according to the horse-power and value in England, though for third-party risk horse-power alone is considered.

Commercial Vehicles.—Under this heading are included all vehicles other than those mentioned previously and motor-cycles. The section provides for vehicles driven by petrol, steam or electricity whatever may be their use. For rating purposes these must of necessity be divided into appropriate classes, as, for example, private-type cars used for business purposes, rateable similarly to private cars; light and heavy goods vehicles each of which is rated according to the district and purpose for which it is used, the former on a horse-power-cum-value basis in addition; private and public hire vehicles rated on horse-power and value; and *chars-à-bancs* rated according to use and seating capacity.

The indemnity granted is more restricted than in the case of the private car policy to the extent indicated above, whilst in addition no provision is made for the driving of the vehicle by any person other than the insured or his servant, nor is the insured covered whilst driving a vehicle not belonging to him. It should be observed that whilst the private car policy indemnifies the insured in respect of his liability to passengers this risk is not covered under the commercial policy unless further premium is paid. Amongst the additional benefits which may be covered on payment of further premium are compensation for loss of use and, if the vehicle is steam driven, an indemnity for claims due to sparks and ashes escaping from the vehicle and explosion risks.

Motor-cycle.—In many respects insurances for motor-cycles are similar to private and commercial vehicle policies, except that even the private cycle policy does not indemnify the insured in respect of claims made by passengers unless additional premium is paid. Further, the cover is normally operative only whilst the cycle is being driven by the insured or, in the case of a commercial cycle, by the insured or his employees. Pillion riding suspends the policy cover unless an additional premium has been paid.

Motor Traders.—Difficulties arise over the insurance of vehicles for such traders, as it frequently happens that for most cars they are only temporarily responsible. Several methods have been devised to overcome this difficulty, the commonest of which entails the payment of premium based upon the number of identification plates held by the insured. Alternatively, tickets supplied by the insurers must be produced by the insured's driver to a policeman upon the occurrence of an accident, the premium being computed upon the number of tickets issued. Such policies cover the road risk only. Within recent years so-called "internal risk" policies have been issued designed to indemnify garage proprietors in respect of claims for accidents to customers' cars occurring upon their own premises. (A. G. M. B.)

American Practice includes five distinct types of coverage:

Public Liability is imposed by law on the owner for injuries or death suffered accidentally or alleged to have been suffered through the use of his automobile. The usual protection granted by such a policy covers the defence of all claims and suits for injury caused by the insured; the assumption by the insurance company of all costs incurred with its consent; the payment of all costs charged to the insured in the suit; the payment of all interest accruing and the repayment of any expense incurred in providing immediate and necessary relief to the injured at the time of the accident. The ordinary form of public liability insurance is usually limited to $5,000 for one person. The policy usually covers a person, a firm or corporation responsible for the operation of the car. The policy usually also covers any adult member of the insured's family, but not a chauffeur or a servant unless the policy is so indorsed.

Property Damage insurance is generally written with public liability insurance and sometimes with fire insurance. The policies cover against losses caused by any damage that the insured car has caused to the property of other persons, and any loss due to th

inability to use the damaged or destroyed property. Damage to the car of the insured, to the property of others while it is being used by or in charge of the insured, is not included.

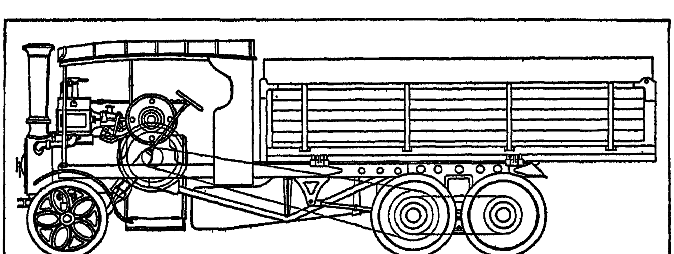
Collision Damage.—These policies protect the owner from any accidental collisions of his car with any other object, either moving or stationary. The insurance company's liability is limited to the actual cost of suitable repairs or replacements or to the actual value of the car at the time of the accident. Protection is limited to specified geographical limits. Damaged tyres are not covered unless there is other injury done to the car. The insurance company does not protect against collision damage incurred while racing or while the car is operated by a child under the age of 16. The rates are based on the degree of coverage, the territory, the age and the type of the car, the motive power, the bumper equipment and a classification based on price and size.

Fire and Transportation.—The protection against fire covers the body, the machinery and the equipment of the car while in the United States or Canada. The car may be in a building, on a road, in a railroad car or other conveyance, on a ferry, on an inland or coastal vessel. Fire and lightning are covered. Rates depend on use, construction, age of car, motive power and protection devices.

Theft.—This coverage is usually written with fire and transportation insurance and is governed by the same conditions. The theft of the car must be committed by a person other than one in the household or employment of the insured. Cars are divided in classes on basis of price lists. The cheaper cars have higher rates.

Motor vehicle insurance is subject to legislation in many States and there is a definite movement towards universal compulsory public liability insurance.

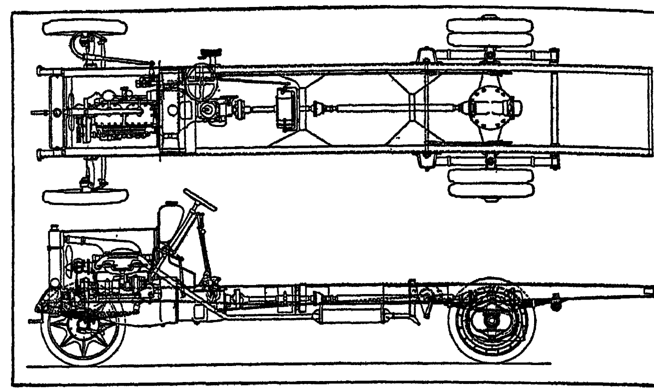
MOTOR VEHICLES, COMMERCIAL. Motor vehicles of commerce, and particularly omnibuses, have long since outlived their early discredit. It took over 200 years to develop horse-drawn vehicles so that one could travel in reasonable comfort at 15m.p.h., and nearly 75 years to develop railways to a similar degree of comfort and reliability for speeds of 50m.p.h. Commercial motors within 16 years reached such a stage of reliability and efficiency that they played a part of the highest importance in the World War. Subsequent progress in design and construction was so rapid that by 1928 the improvement in efficiency was such as to give 60 gross ton-miles per gallon (gross weight, multiplied by distance travelled on one gallon) of fuel consumed under ordinary circumstances, and the use of lorries and passenger vehicles had become a serious menace to any possible railway monopoly of transport. This development resulted from patient and systematic research in thermo-dynamics, metallurgy, petroleum technology, production methods and in the theory of structures. The standardization of materials and parts, the evolution of light-weight, high-grade aluminium alloys at commercial prices, improvements in the construction of pneumatic



FODEN'S OVER TYPE RIGID FRAME 6-WHEELER

tyres and the concurrent study of roads and road constructions are among the other contributory reasons for this rapid development. With each improvement in design and construction motor users have increased their demands for speed and capacity.

Petrol-engined vehicles of the four-wheel type predominate, and the engine usually is mounted over the front axle under a bonnet, but in order to give the maximum length of body for a given overall length, in some cases makers have adopted what is known as the forward drive, in which the driver is seated alongside the engine. The principal disadvantage of this arrangement lies in the engine being less accessible than in the bonnet type, but much ingenuity has been shown in overcoming this, and at least one maker (Pagefield) mounts the radiator, engine and clutch on a sliding sub-frame which may be withdrawn, like a table drawer, the weight meanwhile being partly supported on legs with castor wheels. The question of accessibility is of lesser importance to large users, who can install special appliances for



THORNYCROFT "Q" TYPE CHASSIS FOR LOADS OF 5 TO 6 TONS

dealing with maintenance, than is the case with the small user, who, having no large service organization behind him, must carry out adjustments as and when they become necessary.

As far back as 1898 Thornycrofts introduced a vehicle consisting of a short four-wheeled wagon, on which the forward end of a long two-wheeled trailer was superimposed, the complete vehicle constituting an articulated six-wheeler. It was in advance of its time, and not until 20 years later was interest revived in the type and its economic advantages appreciated for certain services in spite of its many disadvantages, among which is the difficulty of manoeuvring in a backward direction. A few years later the rigid-frame six-wheeler made its appearance, and by 1928 was largely employed. Its chief advantages are that both driving and braking efforts are distributed over four wheels instead of two, and as the two driving axles are carried on a bogie, over which the frame and body are mounted, road shocks are greatly minimized. For instance, when one of the driving wheels passes over an obstacle, the frame and body are lifted only one-half the height of the obstacle. It has an additional advantage in that an endless band or track may be fitted over the two driving-wheel tyres on each side, converting the drive into a creeper track or caterpillar, by which means soft and boggy land may be traversed which would usually be impassable for wheeled vehicles. The articulated type of six-wheeler is much used for furniture removal, the transport of liquids in bulk, cable drums and other bulky or heavy loads. In a further development of the articulated type one maker builds a vehicle having eight wheels, the rear four being mounted on two short pivoted axles which are in line on level ground, but which adjust themselves automatically to road inequalities (Plate, fig. 4). By this means heavy loads may be carried without unduly loading any one tyre or causing damage to the road. The rear four wheels act as load carriers only, and the drive is transmitted through the two wheels on the middle axle, the front axle being the steering axle.

Passenger Vehicles.—Before 1918 chassis employed for motor-buses and coaches were similar in most respects to standard 3–4 ton goods vehicle chassis. As the demand for increased speed and comfort became more insistent, designers had to find means of lowering the centre of gravity, lengthening the wheelbase and effecting improvements in springs, brakes and steering gear. Engines and driving gears had to be quieted and made more efficient, and as each new model was produced the platform level was lowered. No sooner had designers produced a reasonable type of chassis for solid tyres than users began to demand pneumatics. Designers were then faced with fresh difficulties, but by 1928 this class of vehicle left little to be desired in the way of safety, comfort, speed and economic running, many saloon buses engaged on inter-urban service being most luxurious. (An innovation in England in 1928 was a London-Liverpool night passenger

MODERN TYPES OF MOTOR LORRIES, OMNIBUSES AND TRUCKS

1. Tractor truck with drop-frame trailer for hauling heavy commodities, such as structural steel and building material. Trailer has four wheels per axle, fitted with solid rubber tyres. The bed, of riveted sheet steel, is dropped to facilitate loading and unloading
2. A modern street sweeper built for the city of Liverpool. It consists of a motor truck with transverse sweeper brush between the front and rear axles. Body and box at rear are useo for tools
3. Scammell six-wheeled frameless petrol tank weapons. Shell-Mex Ltd. own one hundred of these machines
4. Six-wheel electric-drive coach having entrance doors at front and rear; the body construction is similar to that of a railway car
5. Heavy-duty-type tractor truck with tank-type semi-trailer. Oval steel tank has capacity of 3,000 gal. oil and gasolene. The tank is divided into six compartments, each of which may be cleaned through a man-hole at the top
6. Package delivery body mounted on one-ton truck chassis
7. Eight-wheel electric-drive coach used in western United States. This type of public vehicle replaces trolley cars on roads
8. Tractor truck with trailer similar to railway freight car. Used in isolated regions in feeder service to railway main line freight stations
9. Contractors truck of 5-ton capacity, used for general hauling and in building construction. It has a power-operated dump body of steel
10. Twin-coach parlour car for interurban service. Main entrance door at front of coach (right). An emergency door at the rear end (left) gives access to the luggage space
11. Large motor coach in interurban service. It has a raised compartment at the rear, with space beneath for luggage
12. Scammell six-wheeled frameless 2,500 gal. milk tanker. There is an aluminium tank inside the steel shell. Cork insulation. Running between Salisbury and London these machines average about 65,000 miles a year

service, using sleeping coaches, fitted with berths and toilet accommodation; an attendant pressed clothes, served morning coffee, etc., while the inclusive charge was the equivalent of the 3rd-class rail fare.)

Apart from strictly engineering details, pneumatic tyres contributed to the improvement of these vehicles, and by their absorption of road shocks permitted the use of lighter and improved coach work, the construction of which has become as much an engineering as a coach-building matter, because of the extensive use of pressed steel and aluminium panels, brackets, etc. During the same period the design of taxicabs made relatively little progress, but this was due to police regulations which were formulated in the earliest days of motor-cars, and their enforcement prevented the adoption of modern chassis designs. Moreover, the market being a small one, few makers were tempted to build them and the result was stagnation in design. (*See* also OMNIBUS.)

Creeper-track Machines.—Before 1914 the caterpillar or creeper-track principle of propulsion was mainly used on agricultural tractors and for special cross-country service overseas. The principle was developed very largely for military purposes (tanks) from 1914 to 1918, but up to 1918 the tracks were of metal, noisy in operation and very costly to maintain where run on hard roads, although quite satisfactory on dirt roads, sand or boggy land. Shortly after 1918 experiments were made with tracks of rubber and canvas, and this form of track, known as the Kegresse, soon proved that it could travel as well and nearly as fast as pneumatic tyres on the road, traverse the snow-covered roads and passes of the Alps and Pyrenees and negotiate successfully a journey across the Sahara desert or other sandy wastes. Apart from agricultural machines, however, the creeper-track principle appears to have its greatest application for military and overseas purposes.

Motor fire-engines have almost completely ousted horse-drawn steam-driven fire pumps, and as a general rule they are driven by a powerful petrol engine, through a special design of gear-box which permits of the power being transmitted either to the road wheels or to a rotary pump, generally of the turbine type, because of its high efficiency, and the fact that when drawing from a hydrant the initial water-pressure in the main is fully utilized. (*See* also FIRE-ENGINE.)

Among vehicles specially designed for municipal purposes the Karrier and the Pagefield are examples. The former is a machine which sprinkles and sweeps the road and automatically collects the dust into a tipping body (Plate, fig. 2). It is operated by one man, is capable of easy manoeuvring and consequently may be employed at all hours of the day or night without interference with other traffic. The Pagefield machine is intended primarily for the collection of house refuse and consists of a wagon with a telescopic tipping platform, provided with elevating screws and winding gear. Refuse is collected in horse-drawn low-built containers and at predetermined stations a wagon arrives with an empty container, the wagon platform is tipped, its telescopic ramps extended and the empty container lowered. After this the full container is hauled up into its place and then lowered to the travelling position for conveyance to the refuse destructor or tip. By this means enormous quantities of refuse can be dealt with by a comparatively small staff and equipment. In both the examples named the requisite power for the sweeping, winding and elevating mechanisms is provided by the engine through a special arrangement of gears.

Engines.—Commercial vehicle engine requirements differ from those of other vehicles mainly in the necessity for maximum fuel economy, reliable service and durability. A fuel saving of 5% to 10% is of little importance to the owner of a private car but very important to the owner of a fleet of omnibuses, and to obtain it a designer is justified in adopting every known means short of increasing the running speeds unduly beyond those which may be met by the ordinary materials of commerce. Maximum economy of fuel can be obtained only by using a high compression ratio, but this must be limited by the commercial fuels available. For these reasons the side-by-side valve type of engine with a detachable head is the one most commonly employed, as in practice it gives smooth running, the valve tappets do not need frequent adjustment, such adjustment is easily effected, and decarbonizing of the combustion chamber is a simple matter. Collectively these features spell commercial efficiency. Four-cylinder engines are in the majority, but there is an increasing tendency to use six-cylinder engines for large passenger vehicles. Carburetation, ignition, lubrication and other details conform to the generally accepted practices in use on motor engines. Electric starting and lighting are not practicable for goods-delivery vehicles engaged on short distances with many stops, because the travelling time is too short to keep the batteries charged. For long distance work and on passenger service vehicles electric lighting and starting are generally adopted. The unit method of construction in which engine, clutch and gear-box are combined has been widely used for units up to about 30 h.p., but above that power it is more usual to employ separate units. Water cooling is employed for all but light parcel carriers, when the engines are sometimes air cooled. Water circulation is generally effected by the natural process of convection, but in high-duty engines it is assisted by a pump. In London-type omnibuses the ratio of engine power, at 1,000 revolutions per minute, to total weight is in the region of 4 brake horse-power per ton, but for motor-coaches, in which high point-to-point speeds must be maintained and the vehicle be capable of ascending gradients of 1 in 4, the ratio is usually nearer $6\frac{1}{2}$ b.h.p. per ton. For other classes a usual ratio lies in the region of 5 b.h.p. per ton, with a minimum of about 15 b.h.p. Engine speeds rarely exceed 2,500 revolutions per minute for passenger vehicles and 1,600 r.p.m. for heavy goods vehicles. The latter type should have good pulling capacity at low speeds, with a torque curve fairly flat in its middle range. In Great Britain petroleum spirit or a mixture of petroleum and benzol are the principal fuels. Paraffin is not in much favour for use on road vehicles but is much used for agricultural tractors. From 1914 to 1918 many vehicles were run on coal-gas, which was stored in fabric envelopes at low pressure or in steel cylinders under high pressure. An alternative was to generate gas from coke or charcoal in a producer carried on the vehicle. Alcohol-benzol-petrol mixtures were also used during the same period but found little favour. On the continent, however, the use of alcohol and producer gas has continued to find adherents, but so long as petroleum remains available at commercial prices alternative fuels are likely to receive little encouragement. The Diesel or heavy-oil type of engine makes steady progress in commercial use.

Clutches, Gear-boxes, etc.—The tendency is to fit fabric-faced plate clutches in preference to the cone or the multiple metal-plate type, for the reason that they are smooth in action, easy to adjust and maintain, and make gear changing easy because the spinning parts are of light weight and have low inertia. Except for small load vehicles, four speeds forward and one reverse are provided, the top speed generally being a direct drive. A usual range of speed ratios from engine to propeller shaft is approximately as follow:—first 5; second 3; third 1·75; fourth 1; reverse (min.) 5; reverse (max.) 7·5 to 1, respectively. Sideways or clash engagement gears are most common and although open to many objections are reliable and efficient. Attempts have been made to supplant them by ingenious inventions, but the old-fashioned type still remains the most popular and reliable. Chain-driven gear-boxes, with sliding couplings for engagement, have been used, particularly on London buses, but they are expensive and heavy, and their advantage of silent running has lost importance since the introduction of the gear-grinding process, which makes spur gears practically noiseless.

There are two chief methods of driving-axle construction, *e.g.*, the solid-forged and built-up types. In the former the imposed load is borne by a forged-steel axle shaped like a double-handled banjo, the driving and differential gears being mounted in a casing fitting to the banjo portion, whilst the wheels are mounted on the ends and the driving shafts pass through the hollow ends. This type is adopted extensively. The built-up type, in which the load and gearing are carried entirely by cast casings, finds little favour in Great Britain, but is much used by Continental builders.

For taxicabs and small delivery vans the final drive is generally by bevel gearing with a ratio of about 4·8 to 1, but for other types, and particularly for large passenger vehicles, axles are mostly worm-driven. For heavy-duty lorries, however, the double-reduction gear, by bevel and spur gears, continues in favour among some makers. Axle gear ratios vary from 6½ to 1 for small vans up to 12 to 1 for heavy goods vehicles. For large passenger vehicles the ratio ranges between 7½ and 8½ to 1, according to the class of service. The old system of transmission by chain from a differential countershaft to the road wheels is now employed mainly on steam wagons. Front axles are invariably of the Ackermann type, consisting of a load-carrying beam with pivoted stub axles on which the wheels are mounted. The stub axles are interconnected with each other, and to the steering gear, by levers and connecting rods. When front-wheel brakes are fitted the beam must be made strong enough to resist the braking torque in addition to the load carried on the axle.

The demand for greater loads and increased speeds has necessitated better braking facilities. These have been secured by fitting brakes to both front as well as rear wheels, or by the addition of power-multiplying devices, operated by mechanical, hydraulic or vacuum means, or by a combination of both methods. Modern brakes, when properly adjusted, have an efficiency in some cases approximating to 100% on hard, dry roads.

The spring-suspension system presents great difficulties because of the widely varying loads which have to be dealt with. To meet these and to ensure smooth riding springs are generally made of semi-elliptic shape and of considerable length and breadth. The combined length of one front and one rear spring in the case of a large passenger vehicle is rarely less than 65% of the wheel base. Springs must of necessity be made comparatively stiff and of small camber in order to avoid wide differences in platform height between the laden and unladen conditions, and to minimize these differences auxiliary springs or rubber buffers are frequently fitted.

Steam Wagons.—Interest in steam wagons appears to centre chiefly in Great Britain, though British makers in 1928 exported to South America, India, South Africa and Central Europe. For heavy loads over short or long distances steam wagons compete well with petrol wagons. In the over-type the engine is mounted above a locomotive-type boiler, whilst in the under-type the boiler is usually of the vertical pattern.

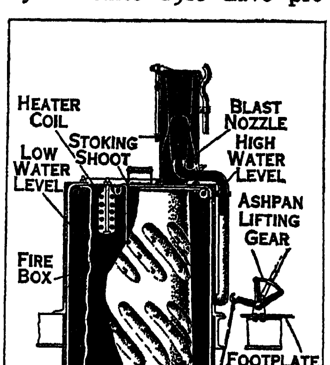

FIG. 2-A.—SENTINEL WATER-TUBE BOILER

As in all other branches, the years since 1918 have produced many improvements in steam wagons. When compound engines are used the high-pressure cylinder is about 4½in. diam., the low pressure 7½in. diam. and the piston-stroke from 7in. to 8in., whilst in twin-cylinder, high-pressure engines, the bore varies from 6in. to 7in. and the stroke from 8in. to 10in. Steam pressures vary from 215 to 275 lb. per sq.in. The grate area is about 3·3sq.ft., and the total heating surface from 60sq.ft. in the case of vertical water-tube boilers to 90sq.ft. in the fire-tube loco-type. Two representative makers are Foden and Sentinel. The former employs a loco-type boiler with a compound engine either mounted above the boiler or below the frame, the drive being taken by a two-speed gear and single chain to the rear axle. The latter employs a vertical water-tube boiler (fig. 2*a*), the inner shell of which has helical-shaped indentations to receive diagonally disposed water-tubes, an arrangement which avoids the need for stay rods; the outer shell may be removed for cleansing the water spaces and tubes. The Sentinel engine has two high-pressure cylinders and is slung beneath the frame, its poppet valves being operated by a camshaft. The crank-case incorporates a two-speed and differential gear from which the final drive to the rear wheels is by separate chains. The Yorkshire wagon is remarkable chiefly for its return-tube boiler (fig. 2*b*), the barrel of which is placed transversely across the front of the wagon, with the fire-box in the centre, thus dividing the products of combustion into two streams, each returning to a central smoke-box and uptake. A vertical compound engine, with its axis lying parallel to the centre line of the wagon, is employed, and drives a differential shaft, whence the final transmission is by a separate chain to each rear wheel. The Atkinson wagon also employs a vertical water-tube boiler, but its engine is of the two-cylinder uniflow type, slung under the frame. This wagon has no change-speed gear, and the final drive is transmitted by a single chain to the rear axle. In a Sentinel rigid-frame six-wheeled steam wagon the four rear wheels are coupled in pairs by roller chains, so that the driving and braking effort is shared by four wheels.

Electric Vehicles.—Electric vehicles which depend upon a storage battery for the source of current, although limited in their sphere of action by the battery capacity, have been developed and used to a considerable extent. There appears to be no standard form of chassis design, as is the case with petrol vehicles, neither is there any agreement on the relative merits of transmission by one or two motors. The motors, however, are usually of the series-wound type, driving the road wheels through spur gearing or by chains. The battery capacity ranges from 30 to 35 miles per charge, and the maximum speed is 14 to 15 m.p.h. for small vehicles, and 9 to 10 m.p.h. for the heavier type, the restricted range and low speeds necessarily limiting the scope of application to such purposes as factory and railway platform trucks, municipal vehicles and town delivery vans.

The trolley bus is a type of vehicle to which much attention was directed during the years 1918 to 1928 as a means of solving the problems of tramway engineers who were faced with the necessity of replacing worn-out rails and rolling stock. It is an electrically propelled vehicle which collects its source of energy by means of a trolley arm from a pair of overhead cables, instead of a single cable and rail return as used on many tramway systems. It is capable of being steered and brought to the edge of the foot-path for picking up and setting down passengers, and in this respect has many advantages over tram-cars, but it lacks one of the chief advantages of motor-bus service in that it must necessarily follow the route of the overhead cable. Unlike a battery-propelled vehicle, however, it may be run at speeds comparable with those of petrol buses, has a high rate of acceleration and low energy cost per bus mile, but at best it is considered only

as a vehicle for use in the transition stage from rail-bound tram-cars to free-moving motor-buses. (*See* also INTERNAL COMBUSTION ENGINE; OMNIBUS; MOTOR TRANSPORT, COMMERCIAL.)

MATERIALS.—The following is a list of materials used in the manufacture of parts: *cylinders*, close-grained cast-iron; *inlet valves*, 3% nickel or medium-carbon steel; *exhaust valves*, case-hardened nickel, 25% nickel or stainless steel; *pistons*, close-grained cast iron or aluminium alloy; *piston rings*, close-grained cast iron; *gudgeon pins*, 3% nickel, nickel-chrome or low-carbon steel case-hardened; *gudgeon-pin bushes*, phosphor bronze; *connecting rods*, 3% nickel, nickel-chrome, medium-carbon steel or duralumin; *bearings*, tin-base white metal; *crankshaft*, 3% nickel, nickel-chrome, chrome-vanadium or medium-carbon steel; *camshaft*, 3% nickel or low-carbon steel, case-hardened; *fly-wheel*, close-grained cast iron, malleable cast iron, cast steel or mild steel; *crank-cases* and *gear-cases*, aluminium alloy or close-grained cast iron; *gear wheels*, case-hardened nickel or oil-hardened and tempered nickel-chrome; *gear shafts*, oil-hardened and tempered 3% nickel or nickel-chrome; *driving worms*, case-hardened low-carbon steel or 5% nickel-chrome; *worm-wheels*, phosphor bronze; *front-axle beams*, medium-carbon steel or 3% nickel; *front-axle stubs*, 3% nickel; *solid-type rear axle*, 3% nickel or medium-carbon steel; *built-up type rear axle*, cast steel or medium-carbon steel casings with 3% nickel or medium-carbon steel sleeves; *steering levers*, 3% nickel or medium-carbon steel; *frame*, 3% nickel or medium-carbon steel; *brake shoes*, malleable cast iron, cast steel or die-cast aluminum alloy; *brake liners*, asbestos fabric; *clutch liners*, asbestos fabric, leather or cork; *brackets*, *levers*, etc., mild steel stampings; *differential cages*, malleable cast iron or mild steel stampings; *exhaust manifolds*, cast iron or malleable cast iron; *inlet manifold*, aluminium alloy; *springs*, silico-manganese or chrome-vanadium; *wheels*, mild steel, cast steel or aluminium alloy.

BIBLIOGRAPHY.—There are but few books on this subject, but a large amount of technical information will be found in the *Proceedings* (1913–27) of the Institution of Automobile Engineers. *See* the following volumes:—*Agricultural Tractors*, xii. and xvi.; *Axles (Live)*, x.; *Automobile Calculations*, xvi.; *Battery and Petrol Vehicles*, xix.; *Brakes*, xix.; *Chain Drives*, xvi.; *Coke Fuel for Commercial Vehicles*, xvi.; *Colonial Vehicles*, xx.; *Engines for Commercial Vehicles*, x.; *Electric Vehicles*, xiiii.; *Four-wheel Brakes*, xviii.; *Four-wheel Drive*, x.; *Gas Traction*, xv.; *Gear Grinding*, xiv., xvi., xvii.; *Heavy Commercial Vehicles*, viii.; *Lubrication of Commercial Vehicles*, xviii.; *Motor Fuel Research Report*, xix.; *Multi-Axle Vehicles*, xviii.; *Multi-Wheel and Track Machines*, xvii.; *Petrol-Electric Bus*, xix.; *Pneumatic Tyres for Heavy Loads*, xx.; *Rail-less Trolley Traction*, xvii.; *Road-less Vehicles*, xvii.; *Springs*, xvi., xvii., xx.; *Steam Commercial Vehicles*, xvii.; *Tractors*, xviii.; *Worm Gearing*, vii., xi. *See also*:—Heap, *Petrol Cars and Lorries* (1922, Pitman); Judge, *Motor Manuals* (1925–26, Chapman and Hall); Russell, *Motor Trucks and Automobile Motors* (1918, Pitman); Jones, *Steam Road Vehicles* (1923, Iliffe); Wimperis, *Application of Power to Road Transport* (Constable); Page, *Modern Motor-Truck Design* (1921, Constable); Schaefer, *Motor-Lorry Design and Construction* (Crosby Lockwood); Elliott, *Automobile Chassis* (McGraw Hill); Oliver, *Motor-Coach Painting* (Crosby); Lewis, *Liquid & Gaseous Fuels* (Constable); *Heavy-Motor-Car (Use and Construction Order (1904)* and *Amendment Orders (1923* and *1927)*, issued by H. M. Stationery Office, London. *See* also volumes of *The Automobile Engineer* (Iliffe), *Motor Transport* (Iliffe) and *The Commercial Motor* (Temple Press). (G. W. W.)

IN THE UNITED STATES

The World War gave a powerful impetus to the commercial vehicle industry, not only because of the large numbers of trucks, ambulances and other vehicles required at and near the battle fronts, but because in some of the countries involved the intense industrial activity overtaxed the capacity of the railroads and called for the provision of additional means of transport. The industry, particularly that branch of it devoted to the production of heavy trucks, outgrew the normal demand for its products, with the consequence that it suffered a serious setback during the industrial depression of 1921. Probably the most noteworthy development in the field of commercial vehicles during the decade which followed the war was the great increase in speed. At the beginning of this period all but the lightest classes were fitted with solid rubber tyres, which, together with the poor state of the roads in the United States, limited speeds to 15 or at most 20 m. per hour. In 1928 most of the new vehicles were equipped with pneumatic tyres. Development of the so called "giant" pneumatic tyre for use on commercial vehicles of the heavier types began during the war period. Tyres as large as 12 in. in width were produced, but it was found that 10 in. was the practical limit, on account of the impossibility of handling the larger size in the event of trouble on the road.

This limitation led to the development of the six-wheeled vehicle (classified into rigid and flexible six-wheelers in England, of which the "rigid" with 4-wheel drive is the dominant type). The U.S. Bureau of Roads showed that the maximum stress developed in the roadway by a six-wheeled vehicle is much less than that developed by a four-wheeled vehicle of equal weight, and several State legislatures recognized this advantage of the six-wheeler and raised its weight limit over that of the four-wheeler. In the United States the six-wheeler was first marketed as an omnibus.

Development in Design.—The increase in the speed of commercial vehicles called for more powerful brakes, and four-wheel brakes were largely adopted. These permitted of stopping in little more than half the distance required with rear-wheel brakes, providing the operator was capable of applying them to the point of practically locking the wheels. This, however, was beyond the strength of the average driver, and power brakes were applied on most of the faster commercial vehicles. One form of brake-applying mechanism, operated by the vacuum in the inlet manifold of the engine, was known as a booster or amplifier. Generally the connections were such that the pull exerted on the brake linkage by a piston in a cylinder was directly proportional to the pressure exerted by the operator on the brake pedal. The operator's pressure on the pedal and the air pressure on the piston combined to apply the brakes. Another device brought out in 1927 to assist the operator's control of a heavy truck is the Bethlehem torque amplifier, by means of which most of the energy required for steering a heavy vehicle could be derived from the engine.

Up to 1926 practically all trucks were equipped with four-cylinder engines, but with the demand for increased speed engines of greater power were necessary, and many manufacturers then adopted the six-cylinder type. Another effect of the demand for increased speed was the adoption of multiple speed transmissions. Up to 1920 the larger trucks generally were provided with four forward speeds. But if a truck was to be capable of high speed when light and at the same time capable of carrying a full load under bad traction conditions, it must have a range of gear speeds of about 8 to 1. Such a range could not be adequately covered with only four gear changes, and trucks designed for this wide range of adaptability were often provided with transmissions giving seven forward speeds.

New Types of Engines.—Several firms in Germany in 1926 and 1927 equipped trucks with light, high-speed Diesel engines. A 5-ton truck of this type equipped with a six-cylinder 70 h.p. engine operating normally at 1,300 r.p.m., was exhibited at the commercial vehicle show in London in 1927. These Diesel engines burned a cheaper fuel (gas oil) than the ordinary truck engines, and also used it more economically, consuming about 0·45 lb. per hp.-hr. at full load, as compared with 0·6 lb., of the common truck engine, while at part load its showing was even better.

In France, beginning in 1923, the Government sought to stimulate the use of producer gas fuel for trucks and other commercial vehicles, the producer gas itself being generated on the vehicle from charcoal or artificial fuels. At first a good deal of trouble was encountered by the engines becoming dirty from impurities in the gas, but devices to cleanse or wash the gas gradually eliminated this trouble.

In 1928 five firms in the United States manufactured electric commercial vehicles operated from storage batteries. The capacities of these vehicles ranged from ½ to 7½ tons. The lighter vehicles had a speed limit of about 15 m. per hour and the heavier of 10 m. per hour, while the distance covered on one charge of the battery ranged around 50 miles. While the largest user in the United States was the American Railway Express Company, these vehicles were also used to a considerable extent by department stores, large bakeries, creameries and meat products firms. The electric truck had proven to be economical in operation, but dependence upon charging stations and low speed retarded its rate of growth. At the commercial vehicle show in London in 1927 two trackless trolley vehicles were shown, one a six-wheeled double-deck omnibus. These vehicles took their current from overhead wires by means of a flexibly-supported trolley pole. They

were much lighter than storage battery vehicles, but required an overhead street electricity supply. In 1928 approximately 300 trolley buses of this type were in use in England.

Transportation by Motor Truck.—The truck was first used chiefly for transportation over short distances, in services in which horses had been used previously; but as its speed and reliability increased the motor truck served between points at greater distances. The maximum distance over which it was profitable to ship goods by truck as compared with shipment by railroad depended upon numerous factors that varied according to the circumstances. This limiting economic radius constantly increased as the mechanical details of the trucks were more thoroughly worked out and as (in the United States) the roads improved.

Some of the reasons which prompted many shippers to employ motor trucks for shipment over comparatively long distances were: reduced cost of packing, loading and unloading, since motor transport requires fewer handlings; saving of time; reduction of capital tied up in empty containers, quick delivery of perishable goods and elimination of the otherwise necessary system of depots.

An important development in the co-ordination of railroad and highway transport was the introduction of container service by several of the railroads in the United States beginning in 1922. Containers with a framework of steel sections and with sheet steel covering, 7 ft. 2½ in. long, 9 ft. 3½ in. wide and 8 ft. 2 in. high, were used for shipping "less-than-carload" lots of merchandise. These containers weighed about 3,000 lb. and could be loaded with merchandise up to 7,000 lb., making the loaded container a capacity-load for a 5-ton truck. Six of these containers could be placed side by side on a 48 ft. low-side gondola car by means of a crane. Loading and unloading the container while on the truck made it unnecessary for the shipper and consignee to have a crane. At the beginning of 1928 three of the larger railroad systems of the United States offered container service between certain of the more important cities along their lines.

Motor Omnibuses.—The early buses were similar in design, so far as the chassis was concerned, to the early motor trucks. A great step in advance was made when the safety bus was developed in 1922. As compared with earlier buses, the chassis was considerably lowered and tread widened; the vehicle, moreover, had an engine of increased power and was equipped with air brakes. In city bus services, where constant stops and starts have to be made, the ordinary sliding gear transmission did not prove as satisfactory as it had in passenger car work, partly because the constant operation of the clutch and the shift lever were a strain on the driver, and partly because the shocks due to constant clashing of the gears were injurious to all parts of the transmission line. It was for this reason that electric drive was introduced.

An electric generator of the compound-wound type was direct-connected to the gasolene (petrol) engine, supplying current to either one or two enclosed electric motors carried on the chassis frame to the rear of the generator, and connected to the rear axle by means of driving shafts with universal joints. Speed control was effected almost entirely by means of the engine throttle. Electrical transmission equipment was more expensive, heavier and somewhat less efficient than a mechanical transmission, but it possessed the advantages of a smooth and uninterrupted acceleration from a standstill to a maximum speed. Such an acceleration assured greater comfort to passengers; maintained a faster schedule; and relieved the strain on the driver, thus tending to reduce accidents.

In 1927 a new design of bus, known as the street-car type, made its appearance. Its object was to provide greater seating capacity for the same over-all dimensions and weight. In the prototype, the Twin-Coach, two separate engines were employed, one under the seats at each side of the bus, each engine driving one of the rear wheels. In later designs a single engine unit was used, located transversely at the extreme rear. In these later vehicles the gas-electric system of transmission was employed, which afforded greater liberty in respect to the location of the engine. That portion of the frame at the forward end of the chassis which is ordinarily occupied by the engine was rendered available for seating space, and the provision of doors at both ends made continuous circulation possible and speeded up traffic.

In 1926 a type of long-distance bus came into use in which the rear half of the floor was raised about 2½ ft. above the forward half, the roof over the rear being equally raised, in the form of a monitor, thus affording a clear vision in all directions. This so-called "observation" bus originated in California, but during the first few years of its existence found its widest application in continental Europe. The space under the floor of the rear, elevated compartment was used for luggage.

Travelling by Motor Bus.—In 1927 it was possible to travel by motor bus between practically all of the larger cities of the United States, and in 1928 a plan of through transportation by bus between New York and San Francisco was in effect. Travel by motor bus was slower than by train, but fares in general were somewhat lower and for many people the bus was more convenient, picking them up practically at their door and carrying them closer to their destinations. Applications for franchises for new bus lines generally were fought by the railroads, while, on the other hand, the railroads engaged in bus transportation themselves, either directly or through subsidiary corporations. In Jan. 1928, the American Railway Association at a meeting in Chicago formally organized a Motor Transport Division.

Before entering into rivalry with the railroads the motor bus had become a serious competitor to electric railways. After early opposition to bus service the street railway interests gradually recognized the bus as a legitimate factor in local transportation, and so proceeded to share in its exploitation. According to a census made by *Bus Transportation,* at the beginning of 1928, 8,482 buses were being operated in public services by American electric railway companies and their subsidiaries, while railway companies and their subsidiaries at the same time operated 994 buses. A very large number of buses (about 32,000 at the beginning of 1927) were used in carrying pupils to and from public and private schools.

The following table shows figures relating to the production and registration of commercial motor vehicles in various industrial countries:

Years	Motor Truck Production			Motor Truck Registration		
	U.S.A.	Canada	Great Britain	U.S.A.	Great Britain*	Germany
1911	10,681	..	..	20,000	53,918	4,206
1914	25,375	..	..	85,000	93,122	9,639
1918	227,250	..	..	525,000	64,399	..
1919	..	7,899	..	..	..	..
1921	..	5,148	..	..	..	31,363
1922	241,049	..	..	1,375,725	237,000	..
1923	..	19,226	21,604	..	..	..
1924	..	..	26,532	..	..	..
1925	..	25,812	32,000	..	..	..
1926	..	..	..	..	..	102,061
1927	455,019	32,556	..	2,941,930	412,374	..

*Great Britain registrations in this table include both vehicles and hackneys.

The average wholesale value of trucks produced in the United States decreased from $1,970 in 1911 to $880 in 1926. Of the trucks produced in the United States in 1926, 13·1% had a capacity of ¾ ton or less; 64·6%, 1 ton; 9·5%, 1½ tons; 4·7%, 2 tons; 3·2%, 2½ tons; 1·4%, 3½ tons; 1·4%, 5 tons, and 2·1%, over 5 tons.

MOTRIL, a town of southern Spain in the province of Granada, at the foot of an offshoot of the Sierra Nevada and on the edge of a rich alluvial plain, about 1 m. from the Mediterranean and 40 m. S.S.E. of Granada. Pop. (1920) 16,809. The climate is semi-tropical, and the *vega* or plain of Motril has been found peculiarly adapted for the culture of sugar-cane and sugar-

beet. In the district, and especially at Salobreña, 3 m. W., there are numerous sugar-factories; cotton is also grown and manufactured, and alcohol, flour, soap, iron goods and cotton stuffs are among the other industrial products. The neighbourhood is rich in zinc and lead; and copper is also found. Grapes, barley, esparto grass, dry figs, almonds and zinc are exported.

MOTT, LUCRETIA (COFFIN), (1793–1880), American reformer, was born at Nantucket, Mass., on January 3, 1793. At 13 she was sent to a Friends' boarding school, at Nine Partners, near Poughkeepsie (N.Y.), where James Mott (1788–1868), whom she married in 1811, was then teacher. Both husband and wife took an active part in the campaign against slavery. About 1840 Mrs. Mott took up the cause of woman's rights. In the course of their work she and her husband travelled extensively on lecture tours. In 1848 she addressed the Anti-Sabbath Convention in Boston, and with Elizabeth Cady Stanton, whom she had first met in London in 1840, called a convention "to discuss the social, civil and religious condition and rights of women," which met at Seneca Falls, and passed a "Declaration of Sentiments," modelled on the Declaration of Independence. Mrs. Mott died on Nov. 11, 1880, near Philadelphia.

See *James and Lucretia Mott; Life and Letters* (1884), edited by their grand-daughter, Mrs. Anna Davis Hallowell.

MOTTEUX, PIERRE ANTOINE (1663–1718), English translator and dramatist, of French parentage, was born at Rouen on Feb. 25, 1663. After the revocation of the Edict of Nantes he settled in London with his kinsman and godfather, Paul Dominique Motteux. He acted as an auctioneer of pictures, and in 1706 he had a shop in Leadenhall Street for the sale of lace, stuffs, Chinese and Japanese commodities, duly advertised in the *Spectator* by his friend Richard Steele. After six years in England he began to edit the monthly *The Gentleman's Journal,* which contained verses by himself and by the chief wits of the day. In 1693 he edited the third book, hitherto unpublished, of Sir Thomas Urquhart's translation of Rabelais, and in 1694 he completed Urquhart's work by a translation of the fourth and fifth books. The translation, though not to be compared with the racy, nervous writing of Urquhart, shows a perfect mastery of colloquial English and an intimate sense of Rabelais's meaning. His *History of the Renowned Don Quixote de la Mancha* (1701), "translated from the original by many hands and published by Peter Motteux," is one of the most masterly and spirited translations in English. He also wrote several plays, including *Love's Jest* (1696). His later years appear to have been given to the shop in Leadenhall Street. He was murdered on Feb. 18, 1718, at a brothel near St. Clement's Church, London. The manner of his death was no criterion of his life, which appears to have been sober.

An excellent life by Henri van Laun is prefixed to the 1880 reprint (4 vols.) of J. G. Lockhart's edition of Motteux's *Don Quixote.*

MOTTEVILLE, FRANÇOISE BERTAUT DE (*c.* 1621–1689), French memoir writer, daughter of Pierre Bertaut, a gentleman of the king's chamber, married in 1639 Nicolas Langlois, seigneur de Motteville, president of the Chambre des Comptes of Rouen. He died two years later at the age of 82, and in 1642 the queen summoned Mme. de Motteville to court. Her chief work is her *Mémoires,* which are in effect a history of Anne of Austria, written briefly till the date of Mme. de Motteville's return to court, and then with fullness. They give a faithful picture of the life of the court at that time.

The best edition of her *Mémoires* is that of M. F. Riaux (2nd ed., Paris, 1891, 4 vols.); Eng. trans. (3 vols., 1902). *See* also E. Angot, *Dames du grand siècle* (1919).

MOTTL, FELIX (1856–1911), German conductor and composer, was born near Vienna, and studied at the Vienna Conservatoire. He made his name as a conductor of Wagner's music, and in 1876 was engaged for the *Ring des Nibelungen* at Bayreuth. From 1881 to 1903 he was conductor at the Carlsruhe Opera, where he produced many works of Wagner and Berlioz. In 1886 he directed the performance of *Tristan und Isolde* at Bayreuth. In later years he visited London and New York, and in 1904 he was made a director of the Academy of Music at Berlin. He composed some operas, of which *Agnes Bernauer* (Weimar, 1880) was the most successful, and numerous songs and other music. He died at Munich on July 1, 1911.

MOUCHEZ, AMÉDÉE ERNEST BARTHÉLÉMY (1821–1892), French astronomer, was born at Madrid of French parents on Aug. 24, 1821. At the age of 16 he entered the naval school at Brest, and then followed a naval career of distinction. On June 27, 1878, he was made director of the National Observatory with the rank of rear-admiral. The 14 years of his directorship were marked by a great increase in the activity of the institution. A spectroscopic department was established, and the gigantic task of re-observing all Lalande's stars was completed. He published 21 volumes of *Annales,* and the first two volumes of the *Catalogue de l'observatoire de Paris;* founded the *Bulletin astronomique,* and set on foot two schools of practical astronomy, one at Paris, the other at Montsouris, for the special instruction of naval and military officers, explorers and surveyors. His most memorable work was the inauguration of international co-operation for charting the heavens. The advances in stellar photography made by Paul and Prosper Henry and others suggested to him the magnificent idea of obtaining, through the collaboration of astronomers in all parts of the world, a chart of the entire celestial sphere containing more than fifty million stars, which should faithfully record in future ages the positions of the stars at the end of the 19th century. He died suddenly at his country seat at Wissous, near Antony, on June 25, 1892.

See *Month. Notices Roy. Astr. Society,* liii. 226; *Observatory,* xv. 305 (D. Klumpke); *Nature,* xlvi. 253; *Rapport annuel sur l'observatoire de Paris pour l'année 1892.*

MOUFLON or **MUFLON,** the wild sheep (*Ovis musimon*) of Corsica and Sardinia, where it is now very local. The ewes are hornless. The rams carry good horns, and in summer show a conspicuous light saddle-shaped mark on the otherwise dark-coloured coat. The Armenian mouflon (*O. gmelini*) of Persia and Armenia is a larger and redder sheep, with the horns curving in the reverse direction. A third, smaller species (*O. ophion*) inhabits Cyprus. *See* SHEEP.

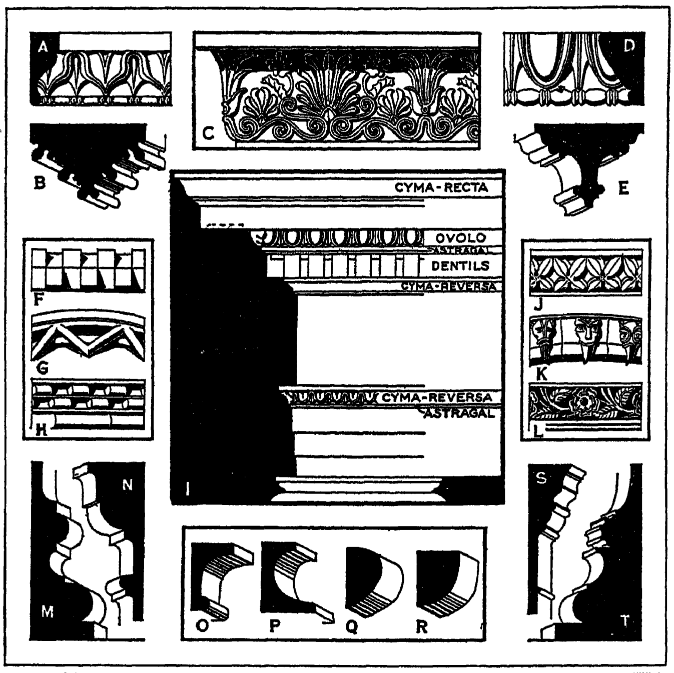
MOULDING in architecture and the decorative arts, a variation and modelling of a surface in a band, approximately continuous, whose profile or section is either always the same, or whose changes are rhythmically repeated. Mouldings are usually classified and named according to their profiles, in three general classes —flat or angular, single curved and compound.

Flat or Angular Mouldings.—(1) *The band, face, or facia:* A continuous member with a flat surface, parallel to the general surface of the wall or feature which it ornaments, and either projecting from, or slightly receding into, this surface. An inclined facia is one whose surface is neither horizontal nor vertical. (2) *The fillet, listel, or regula:* A band or facia, relatively narrow, and usually projecting. Its most common use is to separate curve mouldings, or to finish them at top and bottom. (3) *The chamfer or bevel:* An inclined band, facia or fillet, obtained by cutting off a projecting edge. (4) *Splay:* A large bevel.

Single Curved Mouldings.—(1) *The cavetto:* A hollow moulding whose section approximates a quarter circle, quarter ellipse, or similar curve, with its top and bottom tangent or nearly tangent to horizontal and vertical lines, respectively. (2) *Scotia:* A somewhat similar hollow moulding, whose section is more than a quarter circle or quarter ellipse, so that portions of it recede beyond the general face decorated, forming, thus, a sort of groove. (3) *Flute:* A small groove of either semi-circular, semi-elliptical, or segmental section. (4) *Ovolo:* A convex moulding, whose profile approximates a quarter circle or quarter ellipse. (5) *Torus:* A convex moulding whose profile approximates a semi-circle, or semi-ellipse. (6) *Roll moulding, or bowtell:* A convex moulding, whose profile approximates three quarters of a circle, generally used to decorate a projecting edge. (7) *Astragal:* A small torus, sometimes with fillet attached below. (8) *Apophyge:* A small cavetto, occurring at the top or bottom of a column, baluster, vase or similar form.

Compound Mouldings.—(1) *The cyma recta:* A projecting moulding, of which the portion closest to the original surface is convex, while the more projecting portion is concave; used both

as a crowning mould, when it is sometimes known as a cymatium, with the convex portion below, and also as a base, with the convex portion uppermost. (2) *The cyma reversa or ogee:* A projecting moulding, with the portion nearest the original surface concave, and the more projecting part convex. This, like the *cyma recta*, can be used either as a cap or base moulding. (3) *The bird's beak or thumb moulding:* A moulding with the lower part



(A) GREEK CYMA REVERSA WITH THE WATER LEAF, (C) GREEK CYMA RECTA WITH ANTHEMIONS, (D) GREEK OVOLO WITH EGG AND DART, (I) CLASSIC ENTABLATURE, (M, N) ROMAN BASE AND CAPITAL, (S, T) GREEK BASE AND CAPITAL, (F) BYZANTINE DENTIL, (G, H, J, K) ROMANESQUE, (B, L) ENGLISH GOTHIC, (E) ELIZABETHAN, (O) CAVETTO AND TORUS, (P) SCOTIA, (Q) TORUS, (R) OVOLO

concave, and the upper, more projecting part, convex. The two curves, however, do not merge into each other as in the *cyma reversa,* but intersect in a sharp edge. (4) *Keel-moulding:* A projecting moulding, consisting of a roll moulding or bowtell, with a small fillet attached at its most projecting point.

Decorations.—Mouldings may also be classified according to whether the surface is entirely continuous or undecorated, or whether it is carved. In classic art, decorations almost standard have been developed for various types of mouldings; these decorations, in all cases, are such as to emphasize the general shape or profile of the moulding, and so to emphasize its contour. In general, they are based on carving upon the surface of the moulding ornaments whose basic elements are, in elevation, or front view, curves similar to those of the profile of the moulding. These standard decorations are as follows: (1) For the ovolo, the *egg and dart;* in which egg-shaped solids, with semi-elliptical, projecting frames alternate with long, narrow dart or arrow shapes. The points of greatest projection of the egg, the dart or arrow, and of the frame are all on the surface of the ovolo. (2) For the torus, *wreath forms;* in which many parallel leaves circle the moulding, or bands of *guilloche* (*q.v.*), in which small bands are represented as interlacing and winding around circular buttons. (3) For the astragal, the *bead and reel* (*see* BEAD-MOULDING); in which long, narrow, oval beads alternate with short reel or wheel-shaped forms. (4) For the cyma recta, either successions of *anthemion* (*q.v.*), lotus and honeysuckle forms, or else successions of *acanthus* leaves, either close together or connected by, S-serolls. (5) For the cyma reversa, the *water leaf* or *Lesbian leaf,* which exists in two forms, simple and complex. In the simpler forms this consists of a generally heart-shaped leaf, with a deeply marked mid-rib, and usually a raised frame, alternating either with a dart shape, or a smaller and simpler leaf. In the more complex forms, used by the Romans for large mouldings, the decoration consists of a frame similar in shape to the frame of the simpler leaf. Within the frame, instead of a leaf surface, there is a deeply cut bunch of acanthus foliage, or a little flower. In general, it must be remembered that many mouldings which to-day are undecorated, were painted in Greek, Romanesque and Gothic work.

Egyptians, Hittites, Aegeans.—The historical use of mouldings in the Western world seems to have developed from two, and perhaps three sources: Egyptian, Hittite and possibly Doric or Hellenic. In Mesopotamia, where the chief building material was brick, mouldings were rare or absent in architecture, although they probably occurred in wooden furniture. In Egypt, on the other hand, where first reeds and mud, and later stone were the most common materials, the use of a cornice consisting of a cavetto above with a small torus below was universal. The torus was usually painted to represent a bunch of reeds tied together, and the cavetto with a series of vertical forms, as though to represent the tops of reeds used as walling. Many remains of stone bases, in Hittite sites, show that moulding was a common form of Hittite decoration, and Hittite influence may account for similar forms in Assyrian art and the Persian interest in mouldings on their columns. In Aegean art, on the contrary, mouldings are of little importance, except in the one case of the echinus (*q.v.*), or ovolo used as the capital of a column, as in the stair hall of the palace at Cnossus (*c.* 1500 B.C.), and the door of the *tholos* of Atreus at Mycenae (*c.* 1200 B C.). The latter is noteworthy in that the echinus is carved, and that below it is an apophyge decorated with little, vertical leaves, a form of ornament that also appears on certain early Doric capitals.

Hellenic Influx into Eastern Mediterranean.—This brought a new interest in mouldings, perhaps from an origin in common with the Hittite interest. At first this was tentative only, especially in Greece proper, and the Doric order makes but little use of mouldings except fillets, a small bird beak as a drip at the top of the cornice, and a cymatium on the sloping cornice of a pediment. The most important use of moulding is that in the echinus of the Doric capital, which is probably a development of earlier Aegean forms, and in the delicate mouldings which form the echinus of the anta (*q.v.*) capital. In the ovolo of the echinus there is a continual development from broad, flat, elliptical, much projecting profiles in the early work, through greater and greater refinement, until in such late work as the gate of the Agora at Athens, its sections is almost a straight line.

The greatest development of Greek moulding came through the Ionians of Asia Minor, and the adoption, throughout the Greek world, of the Ionic order, which originated in Asia. In this order, the rectangularity of the Doric yielded to the greatest possible graciousness of moulded surface, and the profiles of the cyma recta of the cymatium, the ovolo and cyma reversa of the bed mould, and the torus and scotia of the base represented, in many cases, the supreme refinement and perfection of curve to which such mouldings can attain. It is characteristic that these mouldings were almost all quirked (having the convex portion brought sharply in at the top to emphasize shadow, and in the cyma reversa, the concave portion also similarly brought out). Furthermore, Greek moulding profiles are always characterized by a constantly changing radius of curvature, and their decorations cut with the most exquisite delicacy.

Roman Architecture.—Mouldings are generally larger, bolder and more obvious, with sections in monumental work usually approximating circular curves, and the units of decoration more widely spaced and thicker, in order to count more strongly at their usually greater distance from the eye than in the smaller Greek examples. In the effort to obtain decorative richness, the Romans also experimented with various new moulding ornaments such as fish scales or imbrications, spiral rope mouldings, rows of flat, vertical leaves, etc. The results, while usually well composed and gorgeous in effect, often lacked the delicacy of Greek examples. In buildings of a smaller scale, such as the houses at Pompeii, all types and characters of mouldings were used; elliptical sections and quirks were common, as well as bevels, inclined planes and sharp, deep hollows.

Eastern Empire.—Byzantine art, with its love of intricately carved, flat surfaces, naturally modified the classic prece-

dents, and tended to substitute flat, inclined faces for all the classic mouldings, replacing richness of curved surface by richness of carved ornament.

Early Romanesque World.—This brought a new feeling into moulding design. Unable, through crudity of technique, to achieve either the refinement of classic profile or the intricacy of Byzantine carving, its mouldings are of the simplest, consisting usually of the roll moulding, or bowtell on the edges of arches, etc., and occasional cavettos and cyma reversas on string courses (horizontal mouldings), cornices and the abaci, or top members, of column capitals. With the developing technique of the later Romanesque period, more complexity of mouldings followed. In many 12th century buildings there is a close approximation of the Roman decorative mouldings, especially in Tuscany, south Italy and Provençe. In Lombardy the development was toward delicacy of scale and a rich use of such simple ornaments as spiral flutings. Norman builders, both in France and England, decorated their mouldings by breaking them into zig-zags, covering them with chevrons, projecting pyramids and birds' heads.

The Late 12th and 13th Centuries.—Gothic mouldings on the continent of Europe still remained simple in profile, and were usually confined to roll mouldings and occasional deep hollows. In cornices and abaci, however, much greater variety was common; cornices were often of cyma profile, or consisted of a cavetto and a torus; decoration with rows of crockets was frequent. Toward the end of the 13th century, the use of the keel moulding for arches, vault ribs, etc., became almost universal, and during the 14th century all mouldings became more and more delicate and attenuated, a development which reached its climax in the complex arch, rib and pier mouldings of 15th and 16th century flamboyant work. These flamboyant mouldings were of the greatest variety, usually with alternations of sharply projecting members, and deeply shadowed hollows; inclined fillets were common and the mouldings of arches and piers, arches and cornices, and gables and cornices were carved as interpenetrating or crossing each other.

English Gothic.—This was entirely different. In the 13th century, Early English and Decorated styles arch mouldings were enormously complex, formed of successions of alternately projecting and receding rounded members, sometimes with inclined fillets separating them, sometimes without fillets, so that the section formed a continuous, much waved line. Cornices were, however, simple, and hollow members were frequently decorated with ball-flowers or pyramid-flowers. Toward the end of the Decorated period (*q.v.*) mouldings became simpler, and their hollows more shallow, and in the Perpendicular period (*q.v.*), a general flatness of effect was common. A characteristic feature of Perpendicular mouldings is the pairing of two cyma curves, and the separation of two such pairs by a wide and shallow hollow. A great richness of carved decoration occasionally took the place of earlier richness of profile and hollow members were carved with realistic vine patterns, or rhythmical repetitions of the Tudor rose, or of square projecting blocks, carved with heraldic insignia or rosettes. During the late Gothic period, both on the continent of Europe and in England, the development of wood panelling created new moulding forms of small scale as decorations around panels (*see* PANEL). The most common form was a small cyma reversa, sometimes with a bead or astragal at the edge of its concave part, which was turned toward the panel.

Renaissance Mouldings.—These were based on classic precedent. The greatest differences were in the early transitional Renaissance style, in which rope mouldings, scale decoration and, occasionally, naturalistic leafage, were common. In the late Renaissance and Baroque the imaginative freedom of the period led to an almost similar freedom from classic correctness. No general forms of importance crystallized from this variety. The much contorted contours of Spanish Baroque, and the characteristic, projecting oval mouldings of the styles of Louis XIV. and XV. (*see* LOUIS STYLES) are typical of late Renaissance freedom.

Mohammedan.—In the Mohammedan countries, mouldings were always subsidiary to surface decoration both in modelling and colour. Projecting corners were often softened by roll mouldings, treated like colonnettes, and moulded cornices occasionally occurred, in Egypt, the Moorish countries and Turkey. In many cases the cornices were supported by stalactite (*q.v.*) ornament. Generally speaking, Mohammedan mouldings throughout were of delicate scale and small projection.

India.—Here, on the other hand, design was of the greatest complexity and variety. In much earlier work, in the north, Greek influence may be seen, but in all the styles throughout the peninsula an inordinate love of complex and repeated shadow lines led to tremendously complex and crowded combinations of mouldings, frequently covering large vertical surfaces. These mouldings were of all possible profiles; cymas, toruses, fillets, bands and ovolos. The ovolo and the torus were often decorated with fish scale or leaf forms, whose effect approximates that of the egg and dart. A somewhat similar richness of moulding invention can be found in the great Cambodian ruins of Angkor Wat.

Far East.—Chinese and Japanese mouldings are simple, and usually restricted to the masonry bases of wooden buildings, wooden doors, stelae (upright memorial structures), and the like. The usual panel mould is a torus of slight projection, but the bases are frequently deeply cut and powerful in design. A noteworthy characteristic is that the base of a building or stele may be carved as though it had legs, like a piece of furniture.

Modern.—Modernistic design is chary in its use of mouldings, which some of its exponents consider unnecessary, and therefore to be avoided. Simplified approximations of classic forms are found, especially in Scandinavian and American modernist work. Where mouldings are found they are used with the utmost freedom from precedent, as in the typical flat, horizontal cymas that formed a band around the "Austrian Building" by Josef Hoffman, at the Paris *Exposition des Arts Décoratifs* (1925). (*See* ORDER and the various historical articles on architecture.)

MOULINS, a town of central France, capital of the department of Allier, 121 m. by rail N.W. of Lyons. Pop. (1926), 20,305. The town is situated on the right bank of the Allier, which is here crossed by an 18th century bridge about 1,000 ft. in length Moulins did not attain any importance till the 14th century, before which it consisted chiefly of some mills belonging to the dukes of Bourbon. About the middle of that century it became the residence of the dukes and in the late 15th century the capital of the duchy. The mediaeval town occupied a small area. The cathedral consists of a huge choir of the 15th and 16th centuries, and a modern nave in early Gothic style, terminated by two towers with stone spires. The church possesses a fine triptych attributed to Domenico Ghirlandajo (d. 1494). A square tower of the 14th century (used as a prison) is the chief relic of the château of the dukes of Bourbon, and there is a belfry of the 15th century. Part of an old Jesuit college serves as the court-house, which contains an archaeological museum. The library, which possesses a valuable Bible of 1115, is part of the *hôtel-de-ville.* Numerous mansions of the 15th and 16th centuries border the streets of the old quarter. The town is the seat of a prefect, a bishop and a court of assizes, and has tribunals of first instance and commerce. It makes beer, cloths, chemicals and furniture.

MOULMEIN or **MAULMEIN,** the port and headquarters of Amherst district and Tenasserim division of Lower Burma. Pop. (1921) 61,301, and the increase in the last half of a century has been very slight. Ship-building, which formerly was an important industry, has now been given up, but there is still a considerable export of teak and rice, and there are several steam rice- and saw-mills. There is railway connection with Rangoon from Martaban, on the opposite bank of the Salween, and from Moulmein itself a railway runs southward to Yè, and is being continued to Tavoy and probably to Siam. River steamers run from Moulmein up the Salween and several of its chief tributaries. The town is protected from the sea by Bilugyun island, and the approach of the port is from the south, pilots being taken aboard at Amherst. The picturesque port, however, is silting up.

MOULTON, LOUISE CHANDLER (1835–1908), American poet, story-writer and critic, was born in Pomfret (Conn.), April 10, 1835, and was educated there and at Miss Willard's seminary in Troy (N.Y.). In 1855 she married a Boston publisher, William U. Moulton, who brought out her earliest literary work in the *True Flag*. Her first volume of collected verse and prose, *This, That and the Other* (1854), was followed by a story, *Juno Clifford* (1855), and by *My Third Book* (1859). Her literary output was then interrupted until 1873 when she resumed activity with *Bed-time Stories*, the first of a series of similar volumes. Through her critiques and literary letters contributed to the New York *Tribune* and Boston *Herald* as well as her Boston salon and her books, she became widely known. In 1876 she published a volume of notable *Poems* (English ed., *Swallow-Flights*, 1877) and visited Europe, where she began close and lasting friendships with men and women of letters. Thenceforward she spent the summers in London and the rest of the year in Boston, where her salon was one of the principal resorts of literary talent. Her later books include *In the Garden of Dreams* (1889), verse; several volumes of prose fiction; and travel sketches. She died in Boston, Aug. 10, 1908.

See Lilian Whiting, *Louise Chandler Moulton, Poet and Friend* (1910).

MOULTON OF BANK, JOHN FLETCHER MOULTON, Baron (1844–1921), British lawyer, was born at Madeley, Salop, Nov. 18, 1844. Educated at Kingswood School, Bath, and St. John's College, Cambridge, he was elected a fellow of Christ's College, and in 1874 was called to the Bar. He specialized in patent law, and rapidly acquired a large and lucrative practice, becoming a Q.C. in 1885. He sat in parliament for Clapham (1885–6) and Launceston (1898–1906). In 1906 he was appointed a lord justice of appeal, and in 1912 a lord of appeal in ordinary, with the title of Lord Moulton of Bank. He died in London on March 9, 1921. During his years on the bench, he rendered distinguished scientific service to the country, as first chairman of the medical research committee under the National Insurance Act (1912), and, during the World War, as chairman of the committee on chemical products and high explosives and director general of explosive supplies in the Ministry of Munitions. He was also chairman of the British Dyestuffs Corporation (1919).

MOULTRIE, WILLIAM (1730–1805), American soldier, was born in Charleston, S.C., on Nov. 23, 1730. His father, a physician, and a graduate of the University of Edinburgh, migrated to Charleston before 1729. The son was elected to the provincial assembly in 1754, 1769 and 1772. Although he was connected by many ties to the British, he espoused the American cause on the outbreak of the Revolutionary War, and was a member of the provincial congress of South Carolina in 1775–76. On Ft. Johnson, on James island in Charleston harbour, he raised what is said to have been the first American battle-flag—blue, with a white crescent in the dexter corner, inscribed with the word "Liberty"; the flag was devised by him in Sept. 1775. In March, 1776, he took command of a palmetto fort which he had built on Sullivan's island, off Charleston, which he held against the attack of Admiral Sir Peter Parker on June 28, and which soon after the battle was renamed Ft. Moultrie by the general assembly. He was thanked by Congress and was made a brigadier-general in the continental army in Sept. 1776. He dislodged the British from Beaufort, S.C., in Feb. 1779, and made it possible for the city of Charleston to put itself into a state of defence. He was one of those who advised against the surrender of Charleston, where he commanded the garrison until the arrival of General Benjamin Lincoln. His imprisonment after the surrender of Charleston (May, 1780) lasted until Feb. 1782. In 1782 he was made a major-general. He was governor of South Carolina in 1785–87 and in 1792–94. He died in Charleston Sept. 27, 1805.

He wrote *Memoirs of the Revolution so far as it Related to the States of North and South Carolina* (1802).

MOULTRIE, a city of southern Georgia, U.S.A., the county seat of Colquitt county; served by the Atlanta, Birmingham and Coast, the Georgia and Florida and the Georgia Northern railways. The population was 6,789 in 1920 (41% negroes) and was 8,027 in 1930 by Federal census. It has a cotton mill, a meat-packing plant, an overall factory, saw mills and turpentine plants, and is the trade centre and shipping point for a rich agricultural region. The city was founded in 1856 and incorporated in 1859.

MOUND, now used in the sense of a pile or heap of earth, especially such a pile raised over a grave or burial-place, a tumulus, or as a means of defence, and so used to translate Lat. *agger*. The word is obscure in origin, but was early influenced by "mount," *i.e.*, hill; Lat. *mons, montis*. A connexion with O.Eng. *mund*, guardianship, hand, has been suggested.

MOUND-BUILDERS, in North America, the name given to the prehistoric inhabitants who chiefly centred in the valleys of the Mississippi and Ohio. The remarkable mounds, which have given occasion for the name, are fortified enclosures and tumuli of the most varied appearance, round, conical, or in the shape of animals. They are scattered over an immense tract of country from the Great Lakes to the Gulf of Mexico, and from the Rockies to the Atlantic, but are specially frequent in the valley of the Mississippi, along its left tributaries, in Arkansas, Kansas and the basin of the Ohio. But the old theory that the mound-builders were a distinct race of highly civilised agriculturalists, who had lived from remote antiquity in the regions of the mounds and were eventually exterminated by the nomadic hordes coming from the northward, represented to-day by the present Indians, is no longer supported by the principal American ethnologists, who hold that the Indians are their descendants.

In Ohio there are thousands of mounds, some in the form of circles, others four-sided, and in a few cases eight-sided. Sometimes a square and a circle are united. Altar-mounds, small rounded heaps of earth, are found in Ohio. At their centre is a basin-shaped mass of hard clay showing effects of fire. These basins are 3 or 4 ft. across, and contain ashes and charcoal. Upon these altars are found many objects.

The most famous mound in Ohio is the "Great Serpent," in Adams county. It lies upon a narrow ridge between three streams which unite. It is a gigantic serpent made in earth. Across the widely opened jaws it measures 75 ft.; the body just behind the head measures 30 ft. across and is 5 ft. high; and, following the curves, the length is 1,348 ft. The tail is in a triple coil. In front of the monster is an elliptical enclosure with a heap of stones at its centre. Beyond this is a form somewhat indistinct, thought by some to be a frog.

In Wisconsin the most interesting mounds are the effigy mounds —earthen forms of mammals, birds and reptiles—usually in groups and of gigantic size. Among them are buffalo, moose, elk, deer, fox, wolf, panther and lynx. Some panthers have tails 350 ft. long, and some eagles measure 1,000 ft. from tip to tip of outspread wings. Occasionally the figures are cut or sunk in the earth, and near them are hundreds of simple burial mounds. The purpose of these effigy mounds is probably totemic, and they were objects of worship as guardians of the villages.

Further south in west Tennessee another class of mound is found. This contains graves made of slabs of stone set on edge. The simplest have six stones, two at the sides, two at the ends, one at the top and one at the bottom. Sometimes there is one of these graves on a mound, sometimes many. In one, 12 m. from Nashville, 45 ft. across and 12 ft. high, were found a hundred skeletons, mostly in stone graves ranged one above the other. The skeletons in the upper graves had been buried stretched at full length. The lower graves were short and square, and the bones in them had been cleaned and piled in little heaps.

The mound-builders were Stone Age men, and made many beautiful objects of stone, shell, bone and beaten metals, but they had no knowledge of smelting. That they were not one race is proved by a study of the skulls from the mounds.

MOUNTAIN TOP VIEW OF CLOUDS AND PEAKS

A sea of clouds about mountain peaks, seen from the crest of Kleinglockner in the Hohe Tauernmass of the Eastern Alps. Mountain climbers in the foreground have reached the top of a peak. Climbing staffs and lifeline are used to ensure a safe ascent and descent

MOUNDSVILLE, a city of West Virginia, U.S.A., the county seat of Marshall county; on the Ohio river, 12 m. S. of Wheeling, at an altitude of 690 ft. It is served by the Baltimore and Ohio Railroad and river steamers, and ½ m. W. is Langin Field, a landing ground of the Army Air Corps. The population was 10,669 in 1920 (89% native white) and was 14,411 in 1930 by Federal census. It is a coal-mining centre and has glass works, zinc smelters, aircraft factories and various other manufacturing industries, with a total factory output in 1925 valued at $8,075,-533. Natural gas is in use. Moundsville was laid out in 1831 and incorporated as a town in 1832. In 1866 it was consolidated with Elizabethtown, half a mile from the river (founded 1798), and was chartered as a city. At the mouth of Grave Creek, nearby, may be seen one of the largest remaining earthworks of the Mound-Builders.

MOUNET-SULLY, JEAN (1841–1916), French actor, was born at Bergerac, on Feb. 28, 1841. He entered the Conservatoire at the age of 21 and took the first prize for tragedy. He served in the war of 1870–71, and had almost decided to remain in the army, though he had been acting for two years before the war. But in 1872 he was asked to play the part of Oreste in *Andromaque* at the Comédie Française. His success in that part assured his return to the stage, and in 1874 he became a *sociétaire*. Perhaps his most famous rôle was that of Oedipus in *L'Oedipe roi*, by Jules Lacroix. This was first performed in the old Roman amphitheatre at Orange in 1888. Mounet-Sully's other famous parts were Achille in Racine's *Iphigénie en Aulide*, Hippolyte in *Phèdre*, Hamlet, the title parts in Victor Hugo's *Hernani* and *Ruy Blas*, Francis I. in *Le Roi s'amuse*, and Didier in *Marion Delorme*. He was created chevalier of the Legion of Honour in 1889. He wrote a play, *La Buveuse de larmes*, and in 1906, in collaboration with Pierre Barbier, *La Vieillesse de Don Juan* in verse. Mounet-Sully died in Paris on March 1, 1916.

MOUNT, WILLIAM SIDNEY (1807–1868), American artist, was born at Setauket, Long Island, N.Y., on Nov. 26, 1807. He studied in the schools of the National Academy of Design, New York, and in 1832 was made a full academician. Among his better-known works are "Turning the Grindstone" and "Farmer's Nooning," Jonathan Sturgis collection; "Turn of the Leaf," Lenox library, New York; "Bargaining for a Horse," New York Historical Society; "Raffling for a Goose," M. O. Robert's collection; "Long Story," Corcoran art gallery, Washington, and "War News," Metropolitan Museum of Art, New York. He died at Setauket, Long Island, on Nov. 19, 1868. His brother, Shepard Alonzo Mount (1804–1868), also an artist, best known as a portrait painter, became a National Academician in 1842.

MOUNTAIN, properly connotes a natural elevation of the earth's surface superior in height to that of a hill; but the distinction often depends on the prominence of a given elevation in relation to its surroundings.

For the classification of mountains according to the various processes of their formation, *see* GEOGRAPHY and GEOLOGY.

MOUNTAIN, THE (*La Montagne*), the name applied during the French Revolution to a political group, whose members, called *Montagnards*, sat on the highest benches in the Assembly. The term, which was first used during the session of the Legislative Assembly, did not come into general use until after the meeting of the National Convention in Sept. 1792. During their struggle with the Girondists, the Montagnards gained the upper hand in the Jacobin club, and for a time Jacobin and Montagnard were synonymous terms.

MOUNTAIN ASH, an urban district of Glamorganshire, Wales, in the Aberdare valley on the Cynon, a west bank tributary of the Taff, 18 m. N.E. of Cardiff, served by the G.W.R. Pop. (1931) 38,381. A branch of the Glamorganshire canal passes through the place. At the beginning of the 19th century Mountain Ash was a small village known only by its Welsh name of Aberpenar, but from 1850, with the development of its collieries, the population rapidly increased. The district has an area of 10,504 ac. and comprises, besides Mountain Ash, a string of villages, the chief being Cwmpenar, Penrhiwceiber, Abercynon and Ynysybwl. The development of the region is associated with the coal exporting phase in the rise of the South Wales industrial area. Trade depression after the World War has seriously affected this region. Mountain Ash shares with Merthyr and Aberdare the services of a stipendiary magistrate.

MOUNTAIN ASH (*Pyrus Aucuparia*). A tree of the rose family (Rosaceae: tribe Pomeae), native to Europe and Asia, so called from its resemblance to the true ash in its smooth grey bark, graceful ascending branches, and the form of the leaf. It is known in Scotland as the rowan tree. The mountain ash attains a height of 50 ft. and is widely cultivated for its handsome foliage and bright red clustered fruit both in Europe and North America where it is sparingly naturalized. The American mountain ash (*P. americana*), a similar but smaller tree, likewise grown for ornament, is native from Newfoundland to Manitoba and south to New York and Minnesota and in the mountains to North Carolina and Tennessee. The still smaller often shrublike western mountain ash (*P. sambacifolia*) occurs from Labrador to New England and north-westward to Alaska and Washington and southward in the Rocky Mountains to Colorado and Utah. By many botanists the mountain ash is separated from the genus *Pyrus* and regarded as part of the genus *Sorbus*.

MOUNTAINEERING, the art of moving about safely in mountain regions avoiding the dangers incidental to them and attaining high points difficult of access. The basis of it is discovery, and in its methods it bears a strong likeness to navigation, demanding many of the same qualities, such as foresight, endurance and ceaseless vigilance. It often resembles arctic exploration and, as its scale increases, partakes more and more of the character of a military expedition. It forms two main divisions, rockcraft and snowcraft. Rockcraft consists in the intelligent choice of a line of route and in activity and gymnastic skill to follow the line chosen. In snowcraft the choice of route is the result of a full understanding of the behaviour of snow under a multitude of varying conditions; it depends largely upon experience and much less upon agility. The dangers, to avoid which the craft of climbing has been developed, are of two main kinds; the danger of things falling on the traveller and the danger of his falling himself. The things that may fall on him are rocks, ice or snow, and he may fall from any one of them or into crevasses in ice. There are also dangers from weather. Thus in all there are eight chief dangers.

Falling Rocks.—Every rock mountain is falling to pieces, the process being specially rapid above the snowline. Rock faces are constantly swept by falling stones which it is generally possible to dodge. Falling rocks tend to form deep and wide channels (*couloirs*) in a mountain face and these channels have to be ascended with caution, their sides being often safe while the middle is stone-swept. Stones fall more frequently on some days than on others according to the recent weather. Local experience is a valuable help on such occasions. The direction of the dip of rock strata often determines whether a particular face is safe or dangerous. The character of the rock must also be considered. Where stones fall frequently débris will be found below, whilst on snow-slopes falling stones cut furrows which are visible from a great distance. In planning an ascent of a new peak such traces must be looked for. When falling stones get mixed in considerable quantity with slushy snow or water, a mud avalanche is formed (common in the Himalaya). It is necessary to avoid camping in its possible line of fall.

Falling Ice.—The places where ice may fall can always be determined beforehand. It falls in the broken parts (*seracs*) of a glacier and from overhanging cornices formed along the crests of narrow ridges. Large icicles are found on steep rock faces, and these fall frequently in fine weather following cold and stormy days. They have to be avoided like falling stones. Seracs are slow in formation and slow in arriving (by glacier motion) at a condition of unstable equilibrium. They generally fall in or just after the hottest part of the day and their débris seldom goes far. A skilful and experienced ice-man will usually devise a safe route through the most intricate ice-fall, but such places should be avoided in the afternoon of a hot day. Hanging glaciers (*i.e.*, those perched on steep slopes), often discharge themselves over

steep rock faces, the snout breaking off at intervals. They can always be detected by their débris below. Their track should be avoided.

Snow Avalanches.—These mainly occur on steep slopes when the snow is in bad condition, early in the year, or after a fresh fall. Days when snow is in that state are easily recognized and then it may be inadvisable to traverse snow-slopes which at other times may be as safe as a high road. Beds of snow collected on rock ledges in bad weather fall off when a thaw comes and are dangerous to rock-climbers. Snow which has recently fallen upon ice-slopes is always liable to slip off bodily. Such falling masses generally make the lower part of their descent by couloirs. Snow avalanches never fall in unexpected places, but have their easily recognizable routes, which can be avoided in times of danger by experienced mountaineers.

Falls from Rocks.—The skill of a rock-climber is shown by his choice of handholds and footholds and his adhesion to those he has chosen. Much depends on a correct estimate of the firmness of the rock where weight is to be thrown upon it. Many loose rocks are quite firm enough to bear a man's weight, but experience is needed to know which can be trusted, and skill is required in transferring the weight to them without jerking. On all difficult rocks the rope is the greatest safeguard for all except the first man in the ascent, the last in the descent. In such places a party of three or four men roped together 15 or 20 ft. apart will be able to hold up one of their number if only one moves at a time and the others are firmly placed and keep the rope tight between them, so that the fall of an individual may be arrested before his velocity is too great. In very difficult places help may be obtained by throwing a loose rope round a projection above and pulling on it; this method (*abseil*) is specially valuable in a difficult descent and has been skilfully developed by Austrian climbers.

The rope usually employed is a strong manila cord, though flax and silk are used by some. On rotten rocks the rope must be handled with special care lest it should start loose stones on to the heads of those below, and similar care is needed for handholds and footholds. When a horizontal traverse has to be made across difficult rocks, a dangerous situation may arise unless there be firm positions at both ends of the traverse. Even then the end men gain little from the rope. Mutual assistance on hard rocks takes all manner of forms; two or even three men climbing one upon another's shoulders or holding up an ice axe to form a foothold for the leader. The great principle is that of co-operation, all the members working with reference to the others and not as independent units; each when moving must know what the man in front and the man behind are doing. After bad weather steep rocks are often found covered with a veneer of ice (*verglas*) which may even render them inaccessible. Climbing irons (*crampons, steigeisen*) are useful on such occasions.

Ice and Snow-slopes.—Crampons are also most useful on ice or hard snow, as by them step-cutting can be reduced and the footing at all times rendered more secure. True *ice*-slopes are rare in Europe though common on tropical mountains, where newly fallen snow quickly thaws on the surface and becomes sodden below, so that the next night's frost turns the whole into a mass of solid ice. An ice-slope can only be surmounted by step-cutting. For this an ice-axe is needed (*pickel, piolet*), the common form having a steel head with an adze-like blade on one side and a long spike on the other at the end of a stick as long as from the elbow to the ground. This serves also as a walking-stick and is furnished with a spike at the foot. Snow slopes are very common and usually easy to ascend. A big crevasse called a *bergschrund* is often found at the point where the steeper final slopes join the glacier or snowfield. Such schrunds are generally too wide to stride across and a snow bridge must be sought, not to be crossed without careful testing and a painstaking use of the rope. A steep snow-slope in bad condition may come away bodily in the shape of an avalanche. Such slopes are less dangerous if ascended directly rather than obliquely; for a line of steps crossing the slope tends to sever it and cause a part to break away. New snow lying on ice is specially dangerous. Experience is needful for deciding on the advisability of advancing over snow in doubtful condition. Snow on rock is usually rotten unless it be thick; snow on snow is likely to be sound. A day or two of fine weather brings snow into sound condition. Snow cannot lie at very steep angles, and seldom exceeds an angle of 40°, though it often deceives the eye. Ice-slopes may be much steeper. In early morning snow is usually hard and safe, but in the afternoon quite soft and possibly dangerous; hence on big mountains a large portion of the work is done before dawn.

Crevasses.—These are the slits or chasms formed in the substance of a glacier, mainly at right angles to its line of movement as it passes over an uneven bed. They may be open or hidden. In the lower part of a glacier they are open. Above the snowline they are frequently hidden by arched-over accumulations of snow and the detection of them then requires care and experience. After fresh snow they can only be discovered by sounding with the pole of the ice-axe, or by looking to right and left where the extension of a hidden crevasse may be traceable. The safeguard against accidents is the rope and no one should ever cross a snow-covered glacier unless roped to one, or better to two, companions.

Weather.—Cold and wet bring the menace of frostbite to toes and fingers, but the main group of dangers caused by bad weather centres in the changes it makes in the condition of snow and rock, making ascents suddenly perilous which before were easy and so altering the aspect of things as to make it hard to find the way or retrace a route. Speed is of vast importance as giving the weather less time for change, so that, broadly speaking, the difficulty of a mountain varies as the height and distance of its summit from the nearest bed. In storm the man who can work by compass has great advantage over a merely empirical follower of his eyes. In large snowfields it is, of course, easier to go wrong than on rocks, but a trained intelligence is the best companion and the surest guide.

Outfit.—Clothing should be as near as possible windproof and wetproof, and coloured or smoked glasses are essential as a protection against the glare of the snowfields; great attention must be given to footgear. For all-round use nothing beats the heavy leather boot suitably nailed; but for special conditions the *abarca* (a crude Spanish moccasin), the *Kletterschuh* (a rag-soled slipper, giving wonderful grip on Dolomite rock), the grass shoe of India and the *alpargata* or *spadrille* of Spain, with its thick and springy hempen sole, are extremely useful. For certain kinds of slabby and difficult rock, thin rubber soles are indispensable.

HISTORY

Systematic mountaineering, as a sport, is usually dated from Sir Alfred Wills' ascent of the Wetterhorn in 1854. The first ascent of Monte Rosa was made in 1855. The Alpine club was founded in London in 1857 and soon imitated in most European countries. Edward Whymper's ascent of the Matterhorn in 1865 marks the close of the main period of Alpine conquest, during which the craft of climbing was invented and perfected, the body of professional guides formed and their traditions fixed.

Passing to other ranges, the exploration of the Pyrenees by Ramond, Packe, Russell and others was concurrent with that of the Alps. The Caucasus followed, mainly owing to the initiative of D. W. Freshfield; it was first visited by exploring climbers in 1868, and most of its great peaks were climbed by 1888. Trained climbers turned their attention to the mountains of North America in that year when the Rev. W. S. Green made an expedition to the Selkirks. From that time exploration has gone on apace, and English and American climbing parties have surveyed most of the highest groups of snowpeaks. The Alps of New Zealand were first attacked in 1882 by the Rev. W. S. Green, and shortly afterwards a local Alpine club was founded and by its activities the range was explored. In 1895 E. A. Fitzgerald made an important journey in this group. Of the high African peaks Kilimanjaro was climbed in 1889 by Dr. Hans Meyer; Mt. Kenya in 1889 by J. E. S. Mackinder and a peak of Ruwenzori by H. J. Moore in 1900.

The Asiatic mountains have as yet been little climbed, though those that lie within the British empire have been surveyed. In

1892 Sir Martin Conway explored the Karakoram Himalayas and climbed a peak of 23,000 ft. In 1895 A. F. Mummery was lost while exploring Nanga Parbat; in 1899 D. W. Freshfield journeyed to the snowy regions of Sikkim, and in 1899, 1903, 1906 and 1908 Dr. and Mrs. Workman made numerous ascents in the Himalaya, including one of the Nun Kun peaks (23,300 ft.). A number of Gurkhas trained in mountaineering by Brig.-Gen. C. G. Bruce have done good service to many explorers.

In 1907 C. G. Bruce, T. G. Longstaff and A. L. Mumm explored the mountains of Garhwal and Kumaon, and Longstaff with A. and H. Brocherel ascended Trisul (23,406 ft.). In 1906 an expedition under the leadership of the Duke of the Abruzzi explored the range of Ruwenzori, on the borders of Uganda and the Congo, and among his ascents were those of Margherita Peak (16,815 ft.) the highest point, Alexandria Peak (16,749 ft.), Elena Peak (16,388 ft.) and Savoia Peak (16,339 ft.).

The most important event of the period 1910–25 was, of course, the assault on Mt. Everest, which is the subject of a separate article (*q.v.*). Everest, however, did not monopolize the attention of Himalayan explorers. Useful work was accomplished by the Workmans during 1911 and 1912 in the Karakoram, by C. F. Meade in the Garhwal Himalaya, by Mr. and Mrs. Visser, by Kellas (who reached a height of 22,700 ft. on Kangchinjhau), and Major H. D. Minchinton, who lost his life in the Himalaya in 1927, did good work in 1926 while on a survey expedition to the Shaksgam district.

The main exploration of the New Zealand Alps was completed before 1910, but Harold Porter's two expeditions (1923 and 1925) proved that interesting pioneer work still awaits the explorer. The Caucasus has been closed to mountaineers since the World War. A British expedition in 1914 made a number of new ascents. Norway still offers the prospect of virgin climbs. Stedtind, described by Cecil Slingsby as "probably the most natural obelisk in the world and the greatest prize in all Scandinavia" was climbed in 1910 by C. W. Rubenson and friends. Three Oxford expeditions to Spitsbergen in 1921, 1923 and 1924, accomplished some excellent work.

Alpine Climbing.—In the Alps practically every peak had been ascended by 1910. No individual climber has a longer list of successes to his credit than G. W. Young. In 1911, with Professor H. O. Jones (killed soon afterwards in the Mt. Blanc range), he completed the ascent of the Brouillard ridge of Mt. Blanc, and achieved the first complete traverse of the great west ridge of the Grandes Jorasses and the first descent of the ridge that descends to the Col des Hirondelles. With Jones and Todhunter, G. W. Young made the first ascent of the Mer de Glace face of the Grepon, and climbed the Gespaltenhorn by the terrible west ridge, perhaps his finest performance. His leading guide on all these climbs was Joseph Knubel, of St. Niklaus. Among other first-class climbs by British mountaineers may be mentioned the conquest of the south face of Mt. Blanc by Oliver and Courtauld with the brothers Aufdenblatten in 1923, and the first crossing of the north face of the Dent d'Herens by a guideless party led by George Finch. The direct ascent of this face was achieved by Weizenbach and Allwein in 1925. The guideless conquest by Raeburn and Ling of the north face of the Disgrazia deserves mention, and also the new Brenva route made in 1927 by F. S. Smythe and T. G. Brown, for the British mountaineers with new climbs to their credit during this period have mostly had to divide it with their guides. On the other hand the Everest expeditions were guideless, as was some of the work done on the American continent by men of the Anglo-Saxon race.

Among other fine Alpine climbs of this period may be mentioned the north arete of Piz Badile by A. Zurchner, led by the guide Walter Risch, an exposed and difficult climb. The ascent of the north face of the Lauterbrunnen Breithorn by Chervet and Richardet, and the variation route taken by Lauper and Liniger up the north face of the Mönch, rank among the great mountaineering exploits, involving as they did, difficult work both on rock and ice. Richardet, Lauper and Chervet were members of the Akademischer Alpen club, Berne. The students of the Berne and Zurich universities have long been known for their mountaineering exploits. One of the last classic problems of the Oberland, the ascent of the Mittelegi ridge of the Eiger, was also solved during this period by a Japanese climber, Yuko Maki, led by the great Grindelwald guide, F. Amatter. Artificial aids were employed for this climb.

French Guideless Climbing.—A great feature of post-World War mountaineering has been the revival of French guideless climbing. Before the war, French climbers of the type of Fontaine were few. Since the war the guideless "Groupe de Haute Montagne" of the French Alpine club have to their credit a consistent record of brilliant work, combining the spirit of adventure with the sane British tradition. The "G.H.M." has been engaged in cairning the last untouched pinnacles of Mt. Blanc, and among its most brilliant achievements may be mentioned the ascent of the north face of the Aiguille du Plan by Lagarde, de Lepiney and de Segogne in 1924.

German Mountaineering.—In the Dolomites and the Kaiser Gebirge German and Austrian climbers have done some very remarkable climbs, but their successes have been paid for by an increasing death-roll. There is a grave tendency among German climbers to take chances, to risk bad weather and impromptu bivouacs. In severity there is nothing to choose between the climbs achieved in the eastern Alps and the new routes which have been made in Cumberland.

The Canadian Alps.—Exploration of the Canadian Alps has been very active. Many fine expeditions have been made, especially by A. H. MacCarthy, Howard Palmer and E. W. D. Holway. Of outstanding importance were the ascents in 1913 of Mt. Robson, culminating summit of the Canadian Rockies (12,972 ft.) by A. H. MacCarthy and W. W. Foster with the Austrian guide Conrad Kain; of Mt. Sir Sandford (11,590 ft.) and of Mt. Adamant (10,980 ft.) by Holway and Palmer; of Mt. Alberta (11,874 ft.) by Yuko Maki of Tokyo and five other Japanese with H. Fuhrer and H. Kohler, and Mt. Woolley (11,170 ft.) by the same party, and the most magnificent achievement of all, the 1925 first ascent of Mt. Logan (19,850 ft.) by a joint party of Canadian and American mountaineers led by A. H. MacCarthy.

No mountain in the Canadian Alps outside the Yukon approaches in technical difficulty a first-rate expedition in Europe. There is less risk of avalanches and the glaciers are much less complicated—on the other hand long distances have to be traversed, while the arranging of transport and camps is a big and expensive business. There is still room for much exploration, although most of the highest peaks in the various groups have been attained, including practically all in the Rockies above 11,000 ft., about 50 in number.

Recent books on special topics are:—
Himalayas: H. R. H. Prince Luigi Amadeo, duke of the Abruzzi, *Karakoram and the Western Himalaya* (1909); Hon. C. G. Bruce, *Twenty Years in the Himalayas* (1910), and *Kulu and Lahoul* (1914); Filippo de Filippi, *Storia della Spedizione Scientifica Italiana nel Himalaia Caracorum* (Bologna, 1924). (*See* also EVEREST.)
The Alps: Sir Claud Schuster, *Peaks and Pleasant Pastures* (1911); Prof. T. G. Bonney, *The Building of the Alps* (1912); Rev. W. A. B. Coolidge, *Alpine Studies* (1912); A. Steinitzer, *Der Alpinismus in Bildern* (1913); Guido Rey, *Peaks and Precipices* (1914); Walter Larden, *Recollections of an Old Mountaineer* (1919); Sir Martin Conway, *Mountain Memories* (1920); F. F. Tuckett, *A Pioneer in the High Alps* (1920); Douglas W. Freshfield, *Life of H. B. de Saussure* (1920), and *Below the Snow Line* (1923); G. I. Finch, *The Making of a Mountaineer* (1924); W. UNITED STATES

Organized mountaineering in America dates from the founding of the Appalachian Mountain club in Boston in 1876 "to explore the mountains of New England and adjacent regions." At that time New England possessed many peaks that had not been climbed. The more active spirits of the club turned their atten-

tion to "the adjacent regions"—a phrase given a most liberal interpretation—with the result that a number of prominent peaks in Colorado capitulated between 1886 and 1889. Following this, the newly opened region of the Canadian Alps came into favour (1890–1900), and members of the club played an important part in exploring their summits. Now, most of the club's activities are in New England. The club had about 4,400 members in 1928.

American mountaineering in its more technical alpine sense was advanced materially by the founding in 1902 of the American Alpine club. This aimed to include in one group the kindred interests of alpinism and arctic exploration; to combine the travellers of high latitudes with the travellers of high altitudes. A more than superficial standard of attainment in both fields was required for membership, and it occupies a distinguished place among mountaineering organizations of the country. In 1916 it established the Bureau of Associated Mountaineering clubs of North America, which in the next 10 years grew to include 71 clubs and societies possessing a combined membership of over 100,000 people. The club contributed substantially, both with funds and personnel, to the successful Mt. Logan expedition of 1925.

In the United States, most of the mountains are of subdued relief, simple in contour and clothed to a large extent with forests. East of the Mississippi river, the highest peaks of the Appalachian system do not much surpass the timber-line and of course fall far short of the line of perpetual snow. In the Western States, the peaks rise farther above timber-line, but again not sufficiently to bring their summits into the realm of perpetual snow, except in the cases of certain isolated volcanic cones. The mountains for the most part resemble the Eastern type, though on a larger and more jagged scale. Dominating peaks may indeed bear large snow banks the year around, and occasional residual glaciers may be found tucked away in sheltered cirques, but in no sense do they challenge the attention of skilled alpinists. As possible exceptions to this generalization may be noted the comparatively compact group of the Olympic mountains in Washington (Mt. Olympus, 8,250 ft., is the highest), the Rockies of Glacier National Park, dominated by Mt. Cleveland (10,438 ft.), the range of the Tetons in Wyoming, of which the Grand Teton (13,747 ft.) is primate, and Mt. Moran (12,100 ft.) next in prominence, the whole perhaps constituting the nearest approach to a genuine alpine configuration to be found within the bounds of the United States proper. (*See* Rocky Mountains, The, and National Parks.)

Colorado and California, despite the multitude and the grandeur of their mountains, fail to satisfy a rigorous alpine standard, although admittedly containing individual summits where technical proficiency in rock climbing does not come amiss. In Colorado are to be found 46 peaks surpassing 14,000 ft. and 300 surpassing 13,000 ft. The best climbs are Lizard Head, first ascended in 1920, and Crestone Needle (14,191 ft.), first ascended in 1916. Difficult rock routes are to be found on many of these great peaks, but there is always an easy side. The Sierras of California boast of the highest peak in the United States, Mt. Whitney (14,501 ft.), and 11 mountains above 14,000 ft. and 150 exceeding 13,000 feet.

This great complex of mountains in the western United States has brought into being a number of organizations devoted to their exploration and conquest—the Sierra club of San Francisco (1892) including some 3,000 members; the Mazamas of Portland (1894) with over 700 members; the Mountaineers of Seattle (1907) having some 850 members and the Colorado Mountain club of Denver (1912) with some 1,200 members. It would not be proper to classify the field work usually accomplished by these organizations as genuine alpine climbing, which is conditioned by the presence of ice and snow as a predominant feature. These great peaks for the most part simply duplicate the winter conditions of such groups as the Adirondacks or White mountains and require no strategy to surmount them.

Such work, however, affords practice on snow slopes and glaciers and may easily develop a penchant for the craft in its advanced aspects. Recently Pacific Coast clubs have visited distant districts where alpine climbing proper could be secured.

Alaska.—Alaska is world-famous for its gigantic mountains and prodigious glaciers, but such climbing as has been accomplished has partaken more of the nature of arctic expeditions than of ordinary mountaineering.

Entirely in character with this land of superlatives is Mt. McKinley (20,300 ft.), the culminating point of North America. Its apex was first attained in 1913 by Dr. Hudson Stuck and Harry P. Karstens in an expedition of three months duration. The previous year Messrs. Browne, Parker and La Voy were driven back by a storm when just short of the summit, a most disheartening climax to their three seasons of persistent and plucky exploration against heavy odds. The North Peak (some 20,000 ft.) was ascended in 1910 by William Taylor and Pete Anderson, Alaska prospectors. Mt. Logan (19,850 ft.), next in rank, was conquered in 1925 by a joint party of Canadian and American mountaineers led by A. H. MacCarthy. It comprised Messrs. H. F. Lambart, W. W. Foster, Allen Carpe, N. H. Read, H. S. Hall, R. M. Morgan and A. Taylor. They were in the field upwards of six weeks, more than half of which was spent on the ice at elevations exceeding 14,000 feet. Two arduous preliminary expeditions, totalling three months and a half, had been made by MacCarthy in establishing supply depots and selecting a route.

Mt. St. Elias (18,024 ft.) was the first great Alaskan peak to fall to the assault of mountaineers. It was ascended in 1897 by a party of ten under the leadership of Prince Luigi, duke of the Abruzzi, following the route explored by I. C. Russell in 1890–91. Mt. Blackburn (16,140 ft.) was conquered in 1912, by Miss Dora Keen and G. W. Handy. The expedition occupied five weeks, of which 13 days of storm were weathered in ice caves dug in the glaciers. The party utilized six men and eight dog sleds for transport. Mt. Wrangel (14,005 ft.), an active volcano, was ascended in 1908 by Robert Dunn and William T. Soule. Mt. Natazhat (13,480 ft.) capitulated in 1913 to an attack by a boundary survey party under the direction of H. F. Lambart, who later ascended Mt. Logan. On no other mountains in the world must the climber live so long on snow and ice as in Alaska, and nowhere else must continuous gradients of snow from 14,000 to 17,000 ft. in height be overcome. (H. Pal.)

MOUNTAIN LAUREL (*Kalmia latifolia*), a North American shrub of the heath family (Ericaceae), called also calico-bush and spoonwood. It is native chiefly to rocky soils from New Brunswick to Ontario and southward to Florida and Louisiana. Usually it is a shrub with very stiff branches, forming dense thickets, 10 to 20 ft. high, but may become a tree 40 ft. high. It bears smooth, oval, pointed laurel-like leaves and handsome pink or white flowers, about 1 in. across, in large terminal clusters.

MOUNTAIN SICKNESS: *see* Anoxaemia.

MOUNTAIN WARFARE. The difficulties attending the prosecution of a campaign in mountains arise primarily from the physical features of the theatre of operations; and secondly, in a marked degree, from the effect those features have in moulding the character of the inhabitants.

Lack of Communications.—A mountainous district is, as a rule, undeveloped; and the means of communications, where any exist, are indifferent or bad. An invader is tied to certain existing roads or tracks as the only method of advance, and has little scope for effecting surprise by means of alternative routes. The observation which the defender can obtain from the hill tops is as good as, and in some ways better than, can be obtained by the invader from aeroplanes. As a result, the invader's intentions can be grasped almost from the start and the uncertainty common to war in normal theatres is largely discounted. The country is usually barren, and all supplies and stores for the invading force have to be carried into the country. Since communications usually consist of mere tracks, or of some boulder-strewn dry river bed, "pack" is the only possible means of transport. Consequently the invading commander is burdened with the guarding of long lines of slow-moving pack animals, and, owing to the fact that they have to convey their own and their drivers' food, they are able only to carry a relatively small useful load.

The climatic conditions in mountains tend to extremes of heat and cold. Changes in weather conditions are also sudden. The melting of snows or the bursting of a thunderstorm in the mountains may mean the flooding of the valley forming the route of

advance, and the washing away of the line of communications "road," which has often been cut out with great labour.

Characteristics of the Inhabitants.—The nature of their surroundings reacts, as elsewhere, on the characteristics of the inhabitants. Their life consists of a struggle with nature. The ease and luxury of the plains is absent. They live scattered in small hamlets close to such patches of ground as will yield to cultivation. Industries are based on the village system, and the local weavers, potters, carpenters and so on supply the needs of the small community. There is no centralised life as in the plains. The inhabitants of a given area (probably emanating from a common stock) usually own a tribal allegiance to each other, but are often again sharply divided into sub-tribes, the boundaries of which are the valleys which they inhabit. Life is hard, and only the physically fit survive early childhood. As a result the characteristics of mountaineers are exceptionally sound physique, bravery, great powers of endurance and ability to thrive on the bare necessities of life. They are, moreover, usually intensely patriotic (for it is a curious and almost universal fact that the wilder a man's country the more attached he is to it). Finally, they fight in mountains in their own element, on ground to which they are accustomed, and which confers on them a mobility twice as great as that of the invading plainsmen.

The above are valuable military attributes. But they are to some extent offset by others. The highly individualistic life in the mountains, whilst leading to an admirable independence, also leads to a lack of centralised purpose and interest. Whilst patriotism for the clan is great, patriotism for the sub-tribe is sometimes greater. There is consequently a tendency toward absence of cohesive effort if the operations be going adversely. This lack of cohesion renders them peculiarly averse to night operations, the success of which against mountaineers is noteworthy throughout history, though it must be added only when most carefully organised and prepared. Nevertheless, mountaineers have always been difficult opponents to overcome.

Operations of Two Kinds.—The consideration of operations in a mountain theatre falls naturally under two heads. First are operations in an area such as the Austro-Italian frontier. There, though the mountains exist, the area has been considerably opened up. Communications are relatively good; heavy stores can be brought up. The forces on both sides are possessed of all the appliances of war. Better theatres for operations exist on the flanks of the mountains, and it is there that the real struggle will be fought out. Neither attacker nor defender is in reality a true mountain race, for national armies are taking part. As a result, the operations tend more and more to take the colour of normal operations in the plains, modified, no doubt, but lacking most of the characteristics of campaigns against true mountaineers. Second are operations in an undeveloped mountain theatre against semi-civilised inhabitants. In describing them the theatre of the North West Frontier of India is taken as an instance.

MOUNTAIN WARFARE IN SEMI-CIVILIZED COUNTRIES

The inhabitants of this area possess all the characteristics noted above. As regards supply during operations, they normally carry seven to 10 days' food on them, and consequently are untroubled by anxiety about their line of communication. They are armed only with rifles and knives. But the rifles are modern for the most part; and it is for consideration whether the power of mobility conferred by such an armament and supply system does not largely compensate for the absence of artillery and other arms. A commander entrusted with the subjugation of a frontier tribe has a difficult task before him. It may be possible to overawe the tribe by air action alone. But targets for aerial attack are limited in such a form of society, and if the opposition of the tribe be determined, air action alone, will seldom suffice; an advance over the ground will, as a rule, be necessary.

Planning the Campaign.—The first difficulty is to select the objective. It can be said at once that the true objective is to bring the enemy to battle. But how is it to be done? Owing to absence of lines of communication, the enemy's strategical mobility is always superior. Owing to his upbringing, his tactical mobility is also superior, except against the best hill troops. Normally, a threat against an enemy's capital forces him to interpose, and brings on a battle. Here, the enemy may not consider any of his hamlets worth defending resolutely. He may prefer to adopt a purely guerrilla attitude, to be ubiquitous, and to worry the advance. That is the most difficult problem to deal with. As a rule he is ready to oppose an advance with resolution in measure as his hopes stand high. If defeated, he tends towards more guerrilla methods. A commander therefore has usually to select the line of advance most likely to produce massed resistance. In doing so he can advance as one column, or by several columns up several valleys. The first method has the advantage of simplicity and of inviting the enemy to concentrate. But the larger the force on one track the slower the movement, and so, if the enemy seeks to avoid decisive battle, the less hope there is of achieving it. A move in several columns has the advantage of speed, and gives greater hope of cornering an elusive enemy. But it involves a series of lines of communication, and is attended by all the difficulties of co-operation and mutual support between columns when separated by mountain ranges.

Progress of Operations.—Whatever the plan the method of conducting operations follows a fairly uniform course. The force advances up a valley protected by a strong advanced guard. This advanced guard throws out detachments to seize and hold tactical points on the hills flanking the valley, and so securing the advance of the column below. These detachments (or "piquets") are withdrawn by the rear guard when the column has passed. Since all commanding ground within rifle range must be denied to the enemy, it is clear that piquets often have to establish themselves 2,000 yd. from the column, and to climb 1,000 ft. or more. The process is therefore laborious and slow, and limits the length of march possible in a day.

Defence at Night.—For the night, all-round defence is essential against so ubiquitous an enemy. Arrangements therefore take the form of a central camp, protected by self-contained piquets posted on tactical points round the camp. These piquets must be sufficient in number, and be placed far enough out, to prevent the enemy firing into camp at night. But since complete protection against such sniping is impossible, a considerable amount of protection against fire has to be provided within the camp. The camp itself has also to be designed and organised to resist assault. It will be realised that there is, in consequence, an immense amount of heavy work to carry out at the end of an exhausting day's advance. Moreover, it is of primary importance that all movement shall have ceased and the camp be made entirely secure before dark. Because, though (as stated above) organised night operations frequently prove successful, unorganised movements are disastrous in face of a ubiquitous enemy who holds the initiative.

It is frequently necessary to raid and destroy villages in order to induce the enemy to stand and fight. Such raids need careful organisation in order to insure that the work is efficiently done in the time available. Raids are usually carried out in various directions, radially, from some semi-permanent camp, the force going out early and returning to camp before dark. The retirement is almost always followed up, and it is in harrying a retirement that the enemy is most dangerous. A running fight (with all its disadvantages) is unavoidable, because the enemy has no columns or guns moving on a road to deploy, but merely follows up deployed. The art of conducting such a retirement consists in the careful and timely laying out of troops in successive positions, so that the retreat of the rearmost is always efficiently covered, and in the skilful co-operation of fighting aeroplanes.

For the defence of the line of communication the system is a chain of piquets in assault proof posts dominating the route. These posts, often 2,000 ft. above the valley, have to be strongly built of dry stone, wired, and the garrisons supplied with food and water for (say) 10 days. It is obvious that the work involved is laborious. At suitable intervals on the line of communication larger posts are established capable of accommodating the convoys passing through. These posts also contain the mobile reserve for their section of the line of communication.

An Example.—Perhaps a small example will best illustrate the difficulties which beset a commander in mountain warfare. A force of four battalions (and attached troops) camps for the night. It is found necessary to use one company per battalion for camp piquets. Next morning the advance continues, but owing to the necessity for an early start it is impossible to relieve the piquets before moving. They must be withdrawn by the rearguard and rejoin units later. So the advance begins with all battalions only three companies strong. "A" battalion gives two companies as advanced guard, one available for piqueting. "B" is allotted entirely for piqueting. "C" heads the main body. "D" finds two companies for rearguard and one as baggage escort. In the advance it is found that piqueting is heavy, that an average of a company to a mile is needed. The force advances four miles (which means that the remaining company of "A" and all "B" battalion are used up on piquet) and is confronted by 1,500 enemy in position. In theory, a brigade is confronted by 1,500 men. In practice 1,500 men are being faced by the two advanced guard companies and the three companies of "C" battalion, perhaps actually some 500 or 600 in all; for that is all that the commander has immediately available. The above crude example is typical of the dispersion of resources inherent in mountain warfare.

As regards mountain warfare in general, history appears to point to two main lessons: firstly, that the true subjection of mountaineers can only be arrived at by opening up and developing the country. Short of that, they may be overawed and pacified for a time, but a change in the undeveloped and individualistic conditions of life is essential to their permanent pacification. Secondly, that if the operations for their primary subjugation are to be quickly and successfully carried out, the forces engaged must be definitely trained to the task, and the personnel composing the force should, as far as possible, be composed of men bred in mountains. (J. P. V.-S.)

MECHANIZATION IN MOUNTAIN WARFARE

With nations which may have to wage war in mountainous countries, and especially with colonial empires, such as the British and the French, military organisation is complicated by the terrain, for obviously mechanized weapons are more suited for warfare on the plains, and the older arms, particularly infantry and mountain artillery, for warfare in the mountains. Generally speaking hill tribes are of an independent spirit, and their social organisation being extremely fluid there is no political centre to strike at, consequently, to bring them to book, they must either be defeated in the field, or their villages, herds or crops must be destroyed. Whilst, until recently, most hill tribes have been indifferently armed when compared to the soldiers of civilised countries, to-day many of them are well equipped with modern rifles, and as they possess a far higher mobility than the drilled soldier, the problem of mountain warfare has become more and more difficult.

In these operations tactics are normally subordinated to the problem of supply, supply being most arduous because of lack of roads, and the difficulty of keeping roads, tracks and valley approaches free from flanking fire. On the North West Frontier of India this problem has been partially solved by constructing a network of strategical lorry roads, and to keep them open armoured cars have proved themselves most useful weapons, since being bullet-proof they reduce the necessity for close road picketing. Should the supply vehicles be also armoured this necessity will still further be reduced, and it will then be possible in all areas traversed by a road rapidly to reinforce and supply in bulk distant garrisons without extensive picketing of the hills; quite possibly whilst the convoys are running this protective duty will be taken over by the aeroplane.

Turning now to the tactical side, the use of the small Renault tank by the French in Morocco has not proved satisfactory. The reason for this is not so much the difficult nature of the ground, as the inefficiency of the machine, which is heavy, under-engined, extremely uncomfortable, and which was never designed for mountain warfare. A close and local study of the North West Frontier of India has led the writer to believe that with a suitable tank the advantages to-day possessed by hill tribes can be greatly reduced. The valleys traversed by rivers of any size should normally present few difficulties to the movement of modern tanks, but it must be realised that it is not in the valleys that the tribesmen fight; further, it must be understood that fighting does not usually take place on the summits of the mountains, but along nullahs, and on such eminences which directly command them, the reason being that nullahs are the only natural, and, frequently, possible, avenues of approach, and further that the native villages are built along them.

In the attack on villages two difficulties are normally met with: The village may be surrounded by sodden rice fields which prohibit the approach of wheeled vehicles, or it may be protected by mud or stone towers. To an efficient tracked machine the first will in most cases be readily overcome, but the second presents this further difficulty: Though the tower can be approached in safety, it is normally of great thickness and little liable to damage by field gun shells; how can it be destroyed? Three courses suggest themselves:—

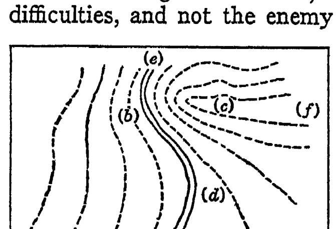
(i.) The tank can haul behind it one or more large oil drums (steel casks) filled with high explosive, and trail these up to the tower, unhitch them close to it, set in action a time fuse, and then retire.

(ii.) The tank can be used as a smoke producing machine, and when the tower is enveloped in smoke, it can be approached by infantry and destroyed in the normal way; or the village can be occupied and its tower, or towers, besieged.

(iii.) The tank can be moved to the foot of the tower, and shells fired through its loopholes. If these shells are filled with lachrymatory chemicals it will be quite impossible for the tribesmen to remain in occupation.

The approach to the village, in all probability a nullah, may run through a gorge, or Tangi, as it is called on the North West Frontier. It is at these gorges the tribesmen gather, and many of them have to be taken by a frontal attack. For infantry the forcing of a gorge is a particularly difficult and dangerous operation. The tribesmen occupy one or both sides of the gorge, and a frontal attack is costly; consequently, when it is possible, an outflanking movement has to be resorted to, for it is common knowledge that, once the tribesmen become aware that their rear is threatened, they retire.

The diagram shows a typical gorge. The nullah is marked by the letters *a–e;* the gorge is at *b,* and the tribesmen are holding the ridge *c.* To occupy this ridge, if infantry alone are used a frontal attack will have to be delivered from *d* on *c;* or, if the ground permits, a flanking movement will have to be made towards *f.* If light tanks are now introduced, these machines can, along a normal nullah, move from *a* to *e* in a few minutes, and deliver a rear fire attack on *c.* The result will be: either the enemy will be shot down as he evacuates *c,* or he will retire without casualties. In either event the gorge ceases to be an obstacle. It is the overcoming of obstacles, such as towers, gorges and supply difficulties, and not the enemy himself, which presents the main



problems in mountain warfare. From the above it will be seen that mechanized weapons are likely to play an important, if not a leading, part in hill fighting, and especially so in uncivilised countries, for in civilised ones this form of fighting is quite secondary to warfare on the plains. Then it will generally be more profitable to cut the enemy's communications and so starve him into surrender, than to enter the mountainous region and directly attack him.

See J. F. C. Fuller, *On Future Warfare* (1927), chaps. ix., xii. and xiv. (J. F. C. F.)

MOUNTAIN WARFARE IN CIVILISED COUNTRIES

In the mountainous parts of Europe the general principles of the art of war lose none of their force. The conduct of operations must be based upon the same strategical and tactical theories as

hold good in the plain. In practice, however, both strategy and tactics must be adapted to the features of the terrain, which give rise to appreciable differences between the two types of warfare. These will now be illustrated, with reference to the considerations given below.

(a) The experience of those armies that have been most engaged in mountain warfare, particularly the Italian army, whose knowledge is based on countless operations in the Alps during the World War, protracted study, and continual exercises both before and since the war.

(b) Features common to all the mountainous parts of Europe: the division of the ground by the mountains into self-contained areas—main valleys of strategic importance and secondary valleys of tactical importance, both in varying degrees presenting difficulties to the development of operations; great differences of altitude and an alternation of practicable and impracticable zones; scanty and protracted lines of communication, with a limited capacity, along the valleys; yet more scanty lateral communications; marked atmospheric changes; violent meteorological phenomena; and limited resources. Such an environment calls for a special organization; it decides the general character of the operations and influences their strategical, tactical and logistical aspects. The rules given below apply primarily to operations in easier and lower country (mountain operations), but brief remarks will also be made about operations in the high mountains (Alpine warfare) and winter operations.

Organisation.—Peace and war experience suggests the following:—*Infantry of the Line:* pack transport for supporting arms (machine-guns, artillery, bomb-throwers), ammunition and general stores; transport services to be organised separately by battalions, pack transport to be used where possible. For operations at greater altitudes there should be *special infantry* like the Italian *Alpini,* organised on the following lines: recruitment from Alpine districts; mountaineer's special clothing and equipment; supporting arms attached permanently to companies; almost exclusively pack transport, organised by companies so that the latter may be very largely independent. *Artillery:* should be easily dismountable so as to be carried as a rule by pack, or sometimes in pieces on light carts or sledges; high-angle fire is preferable; ammunition sections also should have pack transport, at least in part; men and supplies should be freely allotted for liaison and observation work. *Engineers:* sapper and miner battalions furnished with mining apparatus, explosives, drills and portable telpher systems; wireless telegraph, telegraph, searchlight and heliograph sections with portable equipment. *Auxiliary Services:* kitchens and equipment for portable hospitals are essential; medical corps detachments with plenty of stretchers; supply and evacuation arrangements suitable to mountain roads.

General Features of Operations.—The force that can be employed is limited by a logistical saturation-point that cannot be exceeded; with modern technical resources this point is reached less quickly, and large-scale operations can be developed, provided the principle of seeking a decision in the plain is observed. The strength of the terrain and the consequent difficulty of movement produce a situation favourable to the *defensive,* which has, however, the great disadvantage of entailing immobility. *Offensive operations* are difficult, but highly productive. To overcome the adverse combination of enemy and terrain, manoeuvre and surprise must be employed. The former should be designed to avoid any frontal attack, and should be directed towards the enemy's line of retreat, advantage being taken of the intimate connection between valleys, passes and nodal points of communication. Surprise is favoured by the environment, and assists the development of the manoeuvre. Both are difficult to carry out without a thorough knowledge of the country.

Communications are so scanty that a successful manoeuvre may have incalculable results. In the Battle of the Bainsizza (middle Isonzo—August 1917), the success gained by the XXIV. Army Corps in the Vrh valley obliged the Austrians to evacuate their extremely strong positions on the left bank of the Isonzo as far as Monte Santo. In the Battle of Vittorio Veneto, the capture of Trent by the Italian I. Army (Nov. 4, 1918) enveloped and decided the fate of the Austrian units still holding out in the mountainous area between the Adige and the Brenta.

Owing to the broken nature of the terrain, strategical and tactical dispositions have to be made with great care, cannot easily be altered, and must as a rule conform to a prearranged plan. The lack of any continuous field for operations necessitates *division of forces* and *decentralisation of command and supplies.* The commander should indicate the general purpose and objective of the operation, and allow great latitude as regards the means of carrying it out; each unit should be provided with everything required for independent action. *Operations* must be *simple;* when complicated, they often fail even if carefully organised beforehand. The *slow pace* of operations makes it advisable to proceed by stages, each with a separate objective. *Greater length of front* is imposed by the existence of tracts of impracticable country. *Columns* must be *deeper,* and therefore take longer to defile. The health and *moral* of the troops are of the utmost importance.

Factors Affecting Strategy.—Manoeuvre is necessarily controlled by the terrain, larger forces being required where the mountains are narrower, lower and cut by broad valleys. Strategic surprise cannot easily be effected, because the terrain teaches the same lessons to both sides. Concentration calls for night movements, since enemy observation is assisted by the terrain and by premature dispositions. Strategic reconnaissance is difficult. Cavalry can follow only certain fixed lines, and its reconnaissance work must be confined to limited sectors. It cannot be expected to do more than achieve contact with the heads of enemy columns. Aircraft have greater possibilities. Their field of observation is a fruitful one, because the zones occupied by enemy communications are clearly defined. Their work is hampered, however, by atmospheric conditions, deep shadows, extensive forest areas, and the necessity of flying at great altitudes.

The disposition of the major units is a long and difficult operation. The terrain is in favour of economy of force. Great importance attaches to the movement of the general reserve, which is usually conditioned by the road system at the junction of the valleys. If it cannot be moved freely as desired, it may be better to form local reserves. The decision is to be sought by operations wherever they may be expedient—in the bed of the valley, on the slopes, or on the heights. Operations on the heights should not, however, be an end in themselves; every operation should be directed towards opening up the valleys, along which success can be more easily attained. As the "switching" of units is more difficult, it is advisable to adhere to the original plan.

A passive defence will always be enveloped. Movements to repulse enemy threats are hampered by the terrain.

To avoid locking up large forces in passive defence, the defender should always seek to impose frontal action on his opponent. In a defensive campaign also, the movement of the general reserve is of great importance. That it may be readily brought into use, communications will often have to be opened up or repaired, and arrangements made in advance for moving it with transport locally available.

Offensive.—It is preferable to manoeuvre to take the enemy in the rear. For this purpose the action will generally have to be organized for several columns, which will act independently on account of the natural divisions of the terrain. The unity of the whole is secured by accurate preparation of the plan of attack; the following arrangements in particular must be made:—(a) The strength of each column must be limited to that allowed by the terrain (tactical saturation). (b) The time required by each column to attain its objective, every allowance being made for difficulties, must be calculated. (c) Each column must be allotted forces sufficient to allow of the formation of an individual advance-guard and reserve and the provision of auxiliary services (artillery and transport) and the ever-necessary flank- and rear-guards. The allotment of artillery among the columns depends on the width of the sector in which they are to operate. If this does not allow fire along the whole front, the artillery must be divided among the columns; if concentrated battery fire is pos-

sible, the question then arises how many should be allotted to columns and how many kept free for concerted action; also in what direction their march-routes should be assigned so that they may be ready to come in with effect at any stage of the engagement.

(d) Columns should use enveloping tactics within a radius varying with their strength. Weak forces operating within a small radius may not materially affect the issue of the engagement; while strong forces moving in too wide an arc will advance but slowly, leaving the enemy time to counter the threat. (e) The choice of objectives for the columns must be ruled by the terrain, on the principle that the arrival at each objective should facilitate the attack on those that follow. (f) Surprise has always decisive results, because the victim is pinned to the terrain. Every effort should be made to achieve this under cover of night, fog and bad weather. The capture of Monte Nero (middle Isonzo, June 1915) by an Italian Alpine battalion was an admirable instance of a night surprise. A surprise attack is favoured by the use, even if only by small detachments, of routes held to be impracticable. It must, however, be remembered that in mountain warfare the would-be surpriser may himself be surprised, and no precaution against this contingency should be neglected.

(g) The existence of local reserves does not dispense with the formation of a general reserve. The commander must decide whether to despatch it by an independent route or whether, in view of the broken character of the terrain, to make it follow the principal column. In deciding, he must remember that in mountain warfare an extended front means a shallower line, and that delay in the arrival of reserves may have very serious consequences. Local reconnaissance should be carried out by special infantry units pushed far forward from their base. Mountainous country involves reconnaissance along independent lines. One large body sending out patrols in various directions is an unsuitable arrangement; separate duties should from the outset be allotted to units according to circumstances, each unit being given freedom of action. The advance should be made by bounds. The method of approach should be: first, taking advantage of all communications that can be utilised; then, following the ridges, which give a commanding position and allow of deployment on less steep ground. Night marches are often unavoidable. The attack is always slow and difficult, and must be developed systematically. The more broken and uneven the ground, the greater the importance of the manoeuvre even of minor units.

In open country every inch of dead ground must be utilised, suitable formations adopted, and constant support given by artillery and machine-gun fire. Artillery can often support infantry up to the moment of the assault, while machine-guns can fire over the infantry's heads. In close country, where little artillery support is available, infantry can gain their best results by infiltration, systematically supported by their own arms.

As a rule the highest *axes* should be followed, for the sake of the better possibilities of manoeuvring afforded by a commanding position. *Reserve units* can almost always be concentrated under cover at a short distance from the forward troops. The better method of exploiting a success is to push the advance towards the enemy's communications, not to widen the breach. The nature of the engagement and the terrain make it impossible to support the advance with direct artillery fire, which ties the infantry down to a prearranged timetable. On the other hand, since the terrain localises the defence on certain obvious lines, a lifting barrage, the movement of which will be regulated by the infantry, is suitable. Containing actions are always of great value. Tanks can operate in the valleys, on broad passes, and on plateaux, but cannot as yet be used on a large scale.

Defensive.—The positions available permit of effectual resistance, but few are immune from the defect of shallowness, which limits the elasticity of the defence by making the same units responsible for observation and action. Preference should be given to positions which are difficult to outflank and command numerous approaches on a narrow front. In disposing forces it should be remembered that routes regarded as inaccessible are often the most dangerous. The crest of a ridge may be defended on the crest itself, or in front, or behind. Defence on the crest abandons good positions to the attack, offers much dead ground, but affords easy communication with the rear and good cover for reinforcements and reserves. Defence in front of the crest is much exposed to observation, and communications with the rear are difficult; but better observation is possible and there is less dead ground. Defence behind the crest has the quality of offering slight visibility. In practice it is best to seek a solution combining the advantages of all three and avoiding their defects, particularly that of shallowness. It will often be found advisable to establish *advanced centres of resistance.*

To defend a pass occupy the depression and the heights that command it; secure converging fire on the depression; keep reserves on the flanks, towards the heights. If the pass is long, organise several lines of defence; if narrow, command the outlet from positions in the rear. To defend the head of a valley occupy in force the branches forming it; obtain converging fire on the centre of the depression, pushing forward the wings of the position. It is of the greatest importance that machine-gun and artillery fire should be directed in front of the position so as to avoid dead ground. Prompt counter-attacks are most effective, and should be made as the attacking force is about to reach the top of the slope. Local reserves are useful, and the terrain generally allows of their being kept under cover not far from the position.

Artillery barrages should only be placed on ground over which the attack is bound to pass. Containing barrages are always most effectual, because the attacking force is necessarily confined within a few known channels. Trenches, underground posts and dugouts are most useful, but their construction is a long and difficult process; breastworks must often suffice.

Factors Affecting Transport and Supplies.—Owing to the necessity of collecting all local supplies and the small capacity of the railway and road systems—only mule-tracks and footpaths being available on the mountain ridges—the transport problem is immensely important. All existing communications must be systematically brought into use, and every means of transport, particularly pack transport on a large scale, must be utilised. Pack transport will frequently be found insufficient for revictualling the ridges, and telpher systems will have to be constructed. Dumps are useful as ensuring the continuance of supplies if interrupted from the rear; here again telpher lines are desirable.

Alpine Operations.—The special units ("Alpini" and mountain artillery) to which these are entrusted should preferably operate in areas believed to be impassable, or little known, so as to have the advantage of effecting a surprise. They should never be hampered by anxiety for their communications. A concerted attack is out of the question. Companies, and even smaller units, must operate independently, preferably at high altitudes; they should use the method of infiltration and skilfully envelop their opponents, avoiding frontal attacks. Sometimes heavily concentrated fire may be desirable, sometimes silence and a surprise attack with hand-grenades and the bayonet. Generally speaking, the greater the difficulties of the terrain, the greater the necessity for manoeuvring, taking advantage of night,. fog and inclement weather.

Winter Operations.—The inherent difficulties of mountain country are greatly aggravated by frost and snow and their attendant dangers. Winter operations are possible, but are limited to short engagements fought by units formed for the purpose (special infantry with a nucleus of troops on ski; ski units). It is essential to provide special equipment (snowshoes, crampons, white overalls, etc.), commissariat and transport (sleighs for arms and supplies). Thorough organisation and profound experience are indispensable. (A. FER.)

MOUNT AIRY, a town of Surry county, North Carolina, U.S.A., on Federal highway 121, 39 m. N.W. of Winston-Salem. It is served by the Atlantic and Yadkin railway. Pop. (1920) was 4,752 (90% native white); estimated locally at 7,500 in 1928. Mount Airy is a summer resort, in the foothills of the Blue Ridge, at an altitude of 1,150 feet. It has mineral springs, extensive granite quarries, cotton and woollen mills, furniture

factories and tobacco warehouses, and ships large quantities of fruit and honey. The town was incorporated in 1885.

MOUNTBATTEN, the name of an English family of peers. In 1917 the English members of the house of Battenberg, that is to say, the descendants of Princes Louis Alexander and Henry Maurice of Battenberg, renounced their German title and took the surname Mountbatten.

George Louis Mountbatten (b. 1892), who succeeded his father Louis Alexander as marquess of Milford Haven in 1921, married Countess Nadejda Torby, by whom he had one son and one daughter. His sister *Louise* (b. 1889) married Gustavus Adolphus, crown prince of Sweden, and his brother, *Louis Mountbatten* (b. 1900) married Miss Edwina Ashley, as his second wife.

Prince Henry of Battenberg (1858-96), who married Beatrice, youngest daughter of Queen Victoria, had three sons and one daughter. His eldest son *Alexander* (b. 1886) was created marquess of Carisbrooke and earl of Berkhampstead; he married Lady Irene Denison, daughter of the 2nd earl of Londesborough, and has one daughter. The second son, *Leopold,* died in 1922. (*See* also *Milford Haven, Louis Alexander,* and *Battenberg.*)

MOUNT CARMEL, a city of south-eastern Illinois, U.S.A., on the Wabash river, the county seat of Wabash county. It is served by the Big Four and the Southern railways. Pop. (1920) 7,456 and in 1930, 7,132. It is a division point on the Big Four, which maintains repair shops employing 400 skilled mechanics. An outdoor amphitheatre (to seat 25,000) is under construction (1928) on the side of the bluff. The city was founded in 1818.

MOUNT CARMEL, a borough of Northumberland county, Pennsylvania, U.S.A., 50 m. N.N.E. of Harrisburg. It is on Federal highway 120, and is served by the Lehigh Valley, the Pennsylvania and the Reading railways. Pop. (1920) 17,469 and in 1930 it was 17,967. It is an important anthracite-mining centre, and has a number of factories with an output in 1925 valued at $2,989,426. A town was laid out in 1848, and in 1862 the borough was incorporated.

MOUNT CLEMENS, a city of south-eastern Michigan, U.S.A., the county seat of Macomb county; on the Clinton river near Lake St. Clair, 20 m. N. by E. of Detroit. It is on Federal highway 25, and is served by the Grand Trunk and electric railways. The population was 9,488 in 1920, 84% native white, and was 13,497 in 1930 according to Federal census. It is primarily a health resort, visited by 20,000 persons annually. The mineral waters, from wells 1,200 ft. deep, contain a high percentage of solids (125 lb. to each bath of 65 gal.) and are especially efficacious in the treatment of rheumatism. Just east of the city, on Lake St. Clair, is Selfridge Aviation field (1,000 ac.), a training ground of the Army Air Corps. Mount Clemens was settled in 1802, made a village in 1837 and chartered as a city in 1879.

MOUNT DESERT ISLAND lies off the coast of eastern Maine, with which it is connected by a bridge. It is the easternmost and largest island in an archipelago extending from Frenchmans bay to Penobscot bay, the two most beautiful sheets of water on the Atlantic coast. Rock-built and mountainous, it has long been noted for the beauty of its scenery, which led some years ago to the establishment upon it of the first eastern national park in the United States, Lafayette National park. This island was discovered in Sept. 1604, by Champlain in exploration of the Acadian coast from St. Croix westward, and named by him L'Isle des Monts Deserts from his vision of the bare rock-summits of its mountains.

MOUNTFORT, WILLIAM (*c.* 1664–1692), English actor and dramatic writer, played leading parts for the Dorset Garden company. Captain Richard Hill accompanied by Charles, fifth Baron Mohun, murdered Mountfort in Howard street, Strand, on Dec. 9, 1692. Hill escaped. Lord Mohun was tried by his peers and acquitted by a vote of 69 to 14.

MOUNT HOLYOKE COLLEGE, the pioneer institution in America for the higher education of women, situated in the village of South Hadley, Mass., near Mount Holyoke. It was founded by Mary Lyon (*q.v.*) and was chartered as Mount Holyoke Female Seminary in 1836. In 1888 it obtained its college charter, five years later withdrawing the seminary course. The name was changed to Mount Holyoke college in 1893.

MOUNTMELLICK, a market town of Co. Leix, Ireland. Pop. (1926), 2,275. It is the terminus of a branch of the Great Southern railway, 7½ m. N. of Maryborough and 58½ W.S.W. of Dublin. A branch of the Grand Canal provides water communication with Dublin, and with Waterford by the river Barrow. There are industries of malting, tanning, woollen and salt manufactures and iron-founding. A settlement of Quakers has contributed largely to the prosperity of the town. A provincial school of the Leinster Society of Friends was founded here in 1796.

MOUNT PLEASANT, a city in the centre of the lower peninsula of Michigan, U.S.A., 50 m. N. of Lansing, on the Chippewa river and federal highway 27; the county seat of Isabella county. It is served by the Ann Arbor and the Pere Marquette railways. The population was 4,819 in 1920 and 5,211 in 1930. It is the seat of the Central State Teachers college (est. 1892), a shipping point for agricultural produce, and has various manufacturing industries, including factories making beet-sugar, bathroom fixtures and veneer, flour and lumber mills, and a condensed-milk plant. The city was founded in 1875 and incorporated in 1889. Since 1921 it has had a city-manager form of government.

MOUNT PLEASANT, a borough of Westmoreland county, Pennsylvania, U.S.A., 32 m. S.E. of Pittsburgh, on the Baltimore and Ohio railway and Federal highway 119. Pop. (1930) 5,869. It is surrounded by coal mines and has many coke ovens. Other important industries are the manufacture of table glass and fruit jars, lumber, iron, flour and lenses for automobile headlights. The borough was settled about 1782 and incorporated in 1828.

MOUNT PLEASANT, a city of north-eastern Texas, U.S.A., on federal highway 67 and served by the Paris and Mount Pleasant and the St. Louis South Western railways; the county seat of Titus county. Pop. (1920) 4,099 (27% negroes); 3,541 in 1930 by Federal census. It is the trade centre for a rich farming and dairying region; a shipping point for peaches; has mineral springs and lignite mines; and manufactures shirts, pottery, cotton-seed oil and meal, candy, barrel heads and staves, and various other products. The city was founded in 1846 and incorporated in 1900.

MOUNT UNION, a borough of Huntingdon county, Pennsylvania, U.S.A., among the foot-hills of the Alleghenies in the south-central part of the State, on the Juniata river and Federal highways 22 and 622. It is served by the East Broad Top and the Pennsylvania railways. Pop. (1930) 4,892. It has two hydro-electric plants, is an important coal-shipping centre and has large silica-brick plants, creosoting works and other manufacturing industries. The borough was incorporated in 1867.

MOUNT VERNON, a city of southern Illinois, U.S.A., 75 m. E. by S. of St. Louis; the county seat of Jefferson county. It is served by the Chicago and Eastern Illinois, the Jefferson and South-western, the Louisville and Nashville, the Southern and the Missouri Pacific railways. Pop. (1920) 9,815 (94% native white); 12,375 in 1930 by the Federal census. It is the trading centre and shipping point of a rich agricultural and coal-mining region, and manufactures flour, freight cars, shoes, hosiery, furnaces, stoves and various other articles. Mount Vernon was settled in 1819, incorporated in 1837, and chartered as a city in 1872. On Feb. 19, 1888, it suffered severely from a tornado.

MOUNT VERNON, a city in the south-western corner of Indiana, U.S.A., on the Ohio river; county seat of Posey county. It is served by the Chicago and Eastern Illinois, the Louisville and Nashville, and electric railways, and by river steamers and barges. Pop. (1920) 5,284 and 5,035 in 1930. It is a trade centre and shipping point for farmland produce, tractors, flour, paper, lumber, canned vegetables, corn-oil, hickory handles, and other products of its own factories. The first settlement was made in 1803. The town was laid out in 1819, became the county-seat in 1825, was incorporated in 1846, and in 1865 was chartered as a city.

MOUNT VERNON, a town of Linn county, Iowa, U.S.A., on the Lincoln Highway and the Chicago and North Western railway, 16 m. E. of Cedar Rapids. Pop. 1930 (Federal census)

1,441. It is the seat of Cornell college (Methodist Episcopal) opened as a seminary in 1853 and chartered as a college in 1857, which has (1928) an endowment of nearly $2,000,000.

MOUNT VERNON, a city of Westchester County, New York, U.S.A., on the Bronx River, just beyond New York City, between New Rochelle and Yonkers. It is served by the New York Central and the New York, New Haven and Hartford railways. Pop. (1920) 42,726 (24% foreign-born white, of whom over a third came from Italy); 1930 Federal census, 61,499. It is a residential suburb, and has few manufacturing industries. Mount Vernon known as the City of Homes was called "Ten Farms" at first, which was settled from Connecticut in 1664. A free school was established about 1682. St. Paul's churchyard dates back to the close of the 17th century. The church, which has a communion set and a bell sent over by Queen Anne, was begun in 1764, and was used as a British military hospital during the Revolution. Along the White Plains road (now Lincoln avenue) Washington retreated, pursued by Gen. Clinton, before the battle of White Plains (Oct. 1776). The city was founded in 1851 by a company of men from New York city and known as the Industrial Home Association, No. One, incorporated as a village in 1853 and chartered as a city in 1892.

MOUNT VERNON, a city of Ohio, U.S.A., 45 m. N.E. of Columbus, on the Kokosing river; the county seat of Knox county. It is served by the Baltimore and Ohio and the Pennsylvania railways. Pop. (1920) 9,237 (92% native white); 9,370 in 1930 by the Federal census. The city has abundant water-supply, electric power and natural gas, and is an important manufacturing centre, making steam, Diesel and gas engines, structural iron, bottles, window glass and various other commodities. The State sanatorium for the treatment of tuberculosis is here. Mount Vernon was laid out in 1807, incorporated as a town in 1845 and chartered as a city in 1853. It was the birthplace and home of Daniel Decatur Emmett, author of "Dixie," the battle-song of the Confederacy.

MOUNT VERNON, the former home of George Washington, in Fairfax county, Virginia, U.S.A., on the Potomac river, 15 m. below Washington, D.C. The mansion-house, which is the centre of interest, stands on a bluff overlooking the river. The house is built of wood, but the siding is of wide thick boards so panelled as to give the appearance of cut and dressed stonework. The rooms contain much of the furniture which was in them when they were occupied by Gen. Washington and his family; and the furniture that had been lost has been in part replaced by other furniture of historic interest and of the style in use in Washington's day. In the main hall hangs a glass casket containing the key to the Bastille which Washington received from Lafayette in 1790. From each end of the house a curved colonnade and a pavement lead westerly to a row of out-buildings which partially enclose a bowling green and spacious lawn with shaded drives and walks, and beautiful gardens (with trees planted by Washington, Franklin, Jefferson, Lafayette and others). A short distance south-west of the mansion-house and between it and the wharf is a plain brick tomb, which was built by Washington's direction on a site chosen by himself, and contains the remains of Washington and Mrs. Washington (removed to this tomb from the old family vault in 1831), and of about 30 relatives—members of the Washington, Blackburn, Corbin, Bushrod, Lewis and Custis families.

The estate, originally called "Little Hunting Creek Plantation," was devised in 1676 by John Washington (the first of the family in America) to his son, Lawrence, who in turn devised it to his daughter, Mildred, by whom (and her husband Roger Gregory) it was deeded in 1726 to her brother Augustine (George Washington's father). On Augustine's death (1743) it passed to Lawrence (George's half-brother), who built in 1743 the villa which forms the middle portion of the present mansion-house and named the estate Mount Vernon, in honour of his former commander, Admiral Edward Vernon (1684–1757). Lawrence left it (1752) to his widow Anne Fairfax (who in the same year married George Lee) with the proviso that it should pass at her death to George Washington, who meanwhile rented the estate, gaining full possession at her death in 1761. In 1784–85 he enlarged the villa into the mansion-house with its present dimensions by building an addition at each end, erected several of the out-buildings, and adorned the grounds, all according to his own plans and specifications. At Washington's death (1799) Mount Vernon passed to his widow; at her death (1802) it passed to his nephew, Bushrod Washington, and at Bushrod Washington's death (1829) to his nephew John Augustine Washington, who devised it in 1832 to his widow, by whom it was devised in 1835 to their son John A. Washington. This last was authorized by his father's will to sell the estate to the U.S. Government, and in 1847 offered the property for $100,000, but the offer was refused. In 1860 the mansion-house and 200 ac. of the original estate, fast falling into decay, were bought for $200,000 (much of which had been raised through the efforts of Edward Everett) by the Mount Vernon Ladies' Association of the Union. This association under its charter (1856) bound itself to restore the estate as far as possible to the condition in which it was in the lifetime of Washington and to keep it sacred to his memory, and Virginia agreed to exempt it from taxation as long as these terms were fulfilled.

See B. J. Lossing, *The Home of Washington: or Mount Vernon and its Associations* (Hartford, 1870); P. Wilstach, *Mount Vernon* (1916); C. H. Sipe, *Mount Vernon and the Washington Family* (1925); C. Moore, *The Family Life of George Washington* (1926); and E. E. Prussing, *The Estate of George Washington* (1927).

MOURNING: *see* FUNERAL RITES.

MOUSE, in its original sense probably the name of the house-mouse (*Mus musculus*), the type of the genus *Mus* and of the family *Muridae*. The distinctive characters of the typical mice, *i.e.*, those included in the genus *Mus*, are dealt with in the article RODENTIA. With the exception of Madagascar, the genus *Mus*, and its allies, ranges over practically the whole of the Old World, having indigenous representatives even in Australasia; while the house-mouse has established itself throughout the civilized world. *M. musculus*, the house-mouse, originally a native of Central Asia, has spread to all the inhabited parts of the globe. *Apodemus sylvaticus*, the wood or long-tailed field-mouse, is common in many parts of England, often taking to barns and out-houses for shelter during the winter. It is of about the same size as *M. musculus*, but of a bright reddish-grey with a white belly. *Micromys minutus*, the harvest-mouse, is the smallest of the European mice, 2½ or 3 in. in length, and a yellowish-red, with short ears and tail. It lives in wheat or hay fields, where it builds a round grass nest the size of a cricket-ball, in which it brings up its young. Its range extends from England to Japan. In Central Asia there exist wild mice *M. bactrianus*, and *M. wagneri* with the habits of a house-mouse, both closely allied to *M. musculus*; while there is a third kind (*M. gentilis*), also nearly related, in the deserts of North Africa. Mice derived from *M. musculus* are kept as pets in many parts of the world. Numerous breeds are known, of which the Japanese waltzing mice, which have the habit due to a defect in the labyrinth of the ear of spinning round and round after their tails, are perhaps the most remarkable.

THE WHITE-FOOTED MOUSE

See G. E. H. Barrett-Hamilton, "Note on the Harvest-Mice of the Palaearctic Region," *Annals and Magazine of Nat. History* (April 1899); "On the Species of the genus *Mus* inhabiting St. Kilda," *Proc. Zool. Soc.* (1899); "On Geographical and Individual Variation in *Mus sylvaticus* and its Allies," *op. cit.* (1900); W. E. Clarke, "On Forms of *Mus musculus*, with Description of a New Subspecies from the Faeroe Islands," *Proc. Roy. Phys. Soc.* (Edinburgh, 1904), vol. xv. M. A. C. Hinton "Rats and Mice," *Brit. Mus.* (*Nat. Hist.*) *Pamphlet.*

MOUSE-BIRD, the name by which members of the genus *Colius* are known—probably from their habit of creeping along the boughs of trees with the whole tarsus applied to the branch. The colies are placed in the family *Coliidae*, amongst Coraciiform birds, near the trogons and swifts (*q.v.*). The *Coliidae* are small birds, with a rather finch-like bill, a more or less crested head, a very long tail, and generally a dun or slate-coloured plumage that

sometimes brightens into blue or is diversified with white or chestnut. They feed almost wholly on fruits, but occasionally take insects. All the species belong to the Ethiopian region ranging from Abyssinia southwards. There are nine species.

MOUSTACHE or **MUSTACHIO,** the hair worn unshaven on the upper lip (*see* BEARD).

MOUSTERIAN, a name given by the French anthropologist G. de Mortillet to the earliest epoch in his system of cave-chronology, from a cave (Le Moustier) on the right bank of the Vézère, a tributary of the Dordogne, above Les Eyzies, which has yielded typical palaeolithic implements. The epoch was characterized by the Neanderthal type of man, and by the occurrence of the musk ox, the horse, the cave bear, *Rhinoceros tichorhinus,* and the mammoth. The typical implements are flint points or "flake implements," smooth and flat on one side (the "bulbar" surface). Relics of the Mousterian age have also been found in most parts of Europe and in North Africa. An early or proto-Mousterian cave at Krapina, in Croatia, has yielded abundant remains. The Galilee skull was associated with Mousterian implements. The relation of the Mousterian period to the ice age is still obscure, but Mousterian remains are associated with both "warm" and "cold" fauna, and it is reasonable to infer that it "straddled" the last phase of glaciation. Remains have been found at Northfleet and Frindsbury in north Kent, and in Jersey.

BIBLIOGRAPHY.—J. L. Myres, in *Camb. Ancient Hist.,* vol. i. chap. 1 sec. 7 (1924) list of references on pp. 620–621.

MOUTH AND SALIVARY GLANDS. The mouth, in anatomy, is an oval cavity at the beginning of the alimentary canal in which the food is masticated. The opening is situated between the lips, and at rest its width reaches to the first premolar tooth on each side.

The lips are fleshy folds, surrounding the opening of the mouth, and are formed, from without inward, by skin, superficial fascia, orbicularis oris muscle, submucous tissue, containing numerous labial glands about the size of a small pea, and mucous membrane. In the deeper part of each lip lies the coronary artery, while in the mid-line is a reflection of the mucous membrane on to the gum forming the fraenum labii.

The cheeks form the sides of the mouth and are continuous with the lips, with which their structure is almost identical save that the buccinator muscle replaces the orbicularis oris and the buccal glands the labial. In the subcutaneous fascia is a distinct mass of fat, specially large in the infant, which is known as the sucking pad. On the buccal surface of the cheek, opposite the second upper molar tooth, is the papilla which marks the opening of the parotid duct, while, just behind, are four or five molar glands, larger than the buccal, the ducts of which open opposite the last molar tooth. The mucous membrane of the cheek, like that of the rest of the mouth, is of the stratified squamous variety (*see* EPITHELIUM) and is reflected on to the gums.

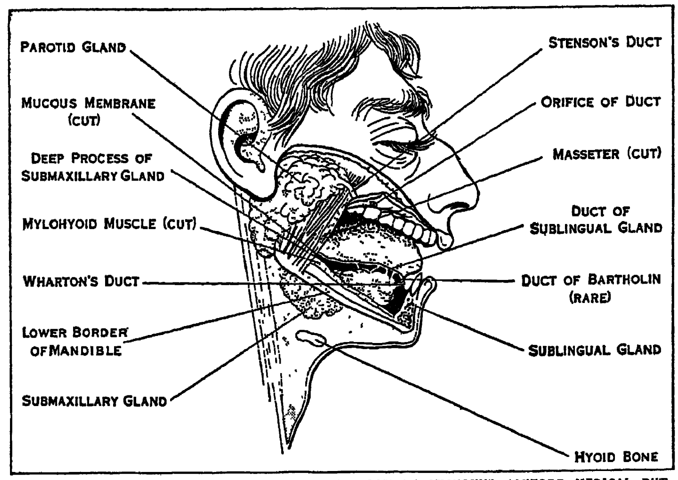
The gums consist of mucous membrane connected by thick fibrous tissue to the periosteum of the jaws. Round the base of the crown of each tooth the membrane rises to a little collar.

The roof of the mouth is concave transversely and antero-posteriorly, and is formed by the hard and soft palate. The hard palate consists of mucous membrane continuous with that of the gums and bound to the periosteum of the palatine processes of the maxillae and palate bones by firm fibrous tissue. In the mid-line is a slight ridge, the palatine raphe, which ends in front in the palatine papilla, marking the position of the anterior palatine canal. From the anterior part of the raphe five or six transverse ridges or rugae of the mucous membrane run outward. (For a description of the soft palate *see* PHARYNX.)

The floor of the mouth can only be seen when the tongue is raised, then the reflection of the mucous membrane from the gums to it is exposed. In the mid-line is a prominent fold (*fraenum linguae*), and on each side of this a *sublingual papilla,* on to the summit of which the duct of the submaxillary gland opens. Running outward and backward from this is a ridge (*plica sublingualis*), which marks the upper edge of the sublingual gland, and on to which most of the ducts of that gland open. (For a description of the TONGUE and the TEETH *see* special articles.)

Salivary Glands.—The salivary glands are the *parotid, submaxillary* and *sublingual,* though the small scattered glands such as the labial, buccal, molar, lingual, etc., probably have a similar function.

The parotid gland is the largest, and is situated between the ear and the ramus of the mandible. In cross-section it is roughly triangular, its outer wall or base being bounded by the parotid fascia,



FROM A. BIRMINGHAM, IN "CUNNINGHAM'S TEXTBOOK OF ANATOMY" (OXFORD MEDICAL PUBLICATIONS)

THE SALIVARY GLANDS AND THEIR DUCTS, WITH THE GREATER PORTION OF THE BODY OF THE MANDIBLE REMOVED TO SHOW THE SUBLINGUAL AND THE DEEPER PARTS OF THE SUBMAXILLARY GLANDS

its anterior by the jaw, and its posterior by the mastoid process and sterno-mastoid muscle. Where the anterior and posterior walls meet to form the apex is the styloid process. Above the gland reaches to the zygoma, and below to the level of the angle of the jaw, where a strong process of the deep cervical fascia separates it from the submaxillary gland. The outline of the gland is obscured by several processes, one of which, the facial lobe, runs forward, superficial to the masseter muscle, accompanying the duct; a separate part of this is called the socia parotidis. Others are pterygoid, pre-styloid and post-styloid, but all are very variable. The facial nerve, the temporo-maxillary vein, and the termination of the external carotid artery, among other structures, are embedded in the gland. The parotid duct (Stensen's duct) crosses the upper part of the masseter and then pierces the buccinator on its way to the mouth; it is about 2in. long.

The submaxillary gland lies deep to the posterior half of the body of the lower jaw; it is about the size of a walnut. The facial artery is embedded in the upper part of the gland. The submaxillary duct (Wharton's duct) runs forward to the sublingual papilla already mentioned.

The sublingual gland is placed farther forward than the submaxillary; it is like an almond in shape though larger; its outer flattened surface rests against the lower jaw; its ducts are small and numerous.

Embryology.—The fore-gut (*see* ALIMENTARY CANAL) at first ends blindly, ventral to the hind brain; in front of it is the overhanging fore-brain. When the heart develops, ventral to the fore-gut, it also projects forward toward the fore-brain, so that a transverse cleft, without any lateral boundaries and lined by ectoderm, is left between these two structures. This is the *stomatodaeum* or primitive mouth, the ectoderm of which rests against the entoderm of the fore-gut to form the *bucco-pharyngeal membrane,* and so separates the two chambers. The position of this membrane does not correspond to the fauces or hinder limits of the adult mouth, but is much more oblique, so that the front part of the roof of the pharynx is formed by stomatodaeum while the greater part of the floor of the permanent mouth is fore-gut. During the third week the membrane disappears, and no traces of it can be seen in the adult. Growing down from the region of the fore-brain is the fronto-nasal process, which forms the nose and the middle piece of the upper lip, while the lateral parts of the mouth are closed in by two processes, on each side of which the lower or mandibular proc-

ess rapidly meets its fellow in the mid-line to form the lower jaw and lip, thus separating the heart from the mouth cavity. The upper or maxillary process grows inward more slowly, but at last joins with the fronto-nasal process, and in the adult the lines of union are seen on each side as ridges of skin which run down from the nostril to the margin of the lip, and enclose that slightly depressed vertical gutter to which the term *philtrum* is given. Besides forming the philtrum the fronto-nasal process is responsible for that part of the roof of the mouth bounded by lines drawn on each side from between the lateral incisor and canine teeth to the palatine papilla. At first the cavities of the mouth and nose are one, but they are later divided by the *palatal processes,* which grow in like shelves from the maxillary processes and meet in the mid-line. The submaxillary and sublingual salivary glands develop as solid outgrowths of the buccal epithelium which are canalized later, while the parotid according to Hammar (*Archiv. f. mikr. Anat.* 1902) appears first as a groove. The parotid is ectodermal in origin, all the others entodermal.

For further details and literature *see* Quain, *Anat.* vol. i. (London, 1908); J. P. McMurrich *Development of the Human Body* (London, 1923); O. Hertwig, *Handbuch der Entwickelungslehre Th. II.* (Jena). *See* also VERTEBRATE EMBRYOLOGY. (W. S. L.-B.)

Comparative Anatomy.—In the Acrania (*Amphioxus*) the mouth is developed on the left side and gradually shifts to the mid-line; later an extra chamber, the oral hood, is formed in front of it, the external opening of which is provided with bristle-like cirrhi, so that in the adult the mouth is merely an aperture in the velum or membrane which separates the oral hood from the pharynx.

In the Cyclostomata (lampreys and hags) the mouth is a suctorial organ, and resembles a funnel, the narrow end of which opens into the pharynx. It is always open and is provided with horny teeth and a tongue. At this low stage of the vertebrate scale no jaws appear, but in the larval lamprey (Ammocoetes) an oral hood, resembling that of *Amphioxus,* is present. In the fishes jaws are present and the mouth can be closed at will. In the elasmobranchs (sharks and rays) the opening is crescentic and situated well on the ventral surface of the head, but in other fishes it is at the anterior end of the body. Until the Dipnoi (mud fish) are reached there is no communication between the mouth and the nose but in these fishes the internal or posterior nares open into the front part of the roof of the mouth, thus adapting them to air-breathing. In the Amphibia the mouth has usually an enormous gape, and the position of the posterior nares resembles that of the Dipnoi. It will be noticed that at this stage of phylogeny the condition resembles that of the ontogeny of man before the palatal processes appear. The premaxillary part of the fronto-nasal process separates the nasal cavity from the mouth in front, but behind that the cavity is the rudiment of the mouth and nose which no palate has yet appeared to separate. In reptiles the hard palate appears, and henceforward the digestive and respiratory tracts only form one passage in the pharynx. In mammals definite lips provided with muscles first appear, though the monotremes have such specialized mouths that lips are not found in that order. Many monkeys have the vestibule enlarged to form the cheek pouches. (F. G. P.)

MOUTH AND SALIVARY GLANDS, DISEASES OF. Most of the conditions affecting these parts have been described under separate headings (*see* TONGUE, DISEASES OF; DENTISTRY; CALCULI; DIPHTHERIA; PHARYNGITIS; TONSILLITIS; MUMPS; ACTINOMYCOSIS) while as constituting the commencement of the respiratory and alimentary systems the mouth shares in some degree in the affections of these systems, as well as in general diseases (*see* SCARLET FEVER; MEASLES; SCURVY; VENEREAL DISEASES; TUBERCULOSIS). A few other aspects of the subject remain to be considered.

Relaxed or Unduly Long Uvula.—Either because of its inordinate length or because it shares in a general pharyngitis the uvula may touch and irritate the back of the tongue leading to irritable cough or repeated attempts at clearing the throat. Usually an astringent gargle is sufficient treatment; formerly a portion of the uvula was burned with caustic or snipped off with scissors, but this procedure is undesirable since removal of too much leads to regurgitation of food or drink through the nose in swallowing from failure of complete coaptation of the uvula and anterior pillars of the fauces.

Xerostomia.—This rare condition is of nervous origin and probably is allied to the deficient secretion of saliva actuated by fear in ancient trials by ordeal. Dryness of the mouth in fever and in bella donna poisoning though equally due to deficient secretion of saliva, is not included under the term.

Salivation results from the action of certain poisons, *e.g.,* mercury, potassium iodide, and accompanies many diseased conditions of the mouth. In cancer of the tongue, floor of mouth, cheek or gingival border, salivation is one of the most distressing symptoms. Mercurial salivation has disappeared largely since modern methods of treating syphilis have been introduced, and at present is mainly the result of industrial conditions.

Ranula is an oral swelling in the floor of the mouth filled with clear fluid; it depends upon accumulation of saliva in the duct of the salivary gland behind an impacted salivary calculus.

"Phossy Jaw" has disappeared since the manufacture of matches with red phosphorus superseded use of the amorphous variety. Formerly it was common owing to the fact that the fumes attacked the jaws of workers in the region of carious teeth; extensive necrosis of the bones of the jaw and falling out of teeth, followed by severe constitutional disease often resulted and death was not uncommon.

Macroglossia and Macrocheilia are rare conditions in which the tongue and lips respectively are enormously enlarged from blockage of their main lymphatic channels. The condition is therefore akin to elephantiasis (*q.v.*). The tongue may be so large that it protrudes from the mouth for several inches.

MOVIMAN, a tribe or small group of tribes of South American Indians, constituting an independent linguistic stock. The Moviman live in north-eastern Bolivia, on the Yacuma river, a western tributary of the Mamore, in S. lat. 14°. They are a tall people, speaking a very harsh and disagreeable language. Their culture was much like that of the Moxos tribe, who were their neighbours on the south.

See A. D'Orbigny, *L'Homme Américain* (Paris, 1839).

MOWBRAY, the name of an Anglo-Norman baronial house, derived from Montbray (Manche) in Normandy south of St. Lo. It was founded at the Conquest by Geoffrey (de Montbray), bishop of Coutances. His nephew Robert, who rebelled with him against William Rufus on the Conqueror's death, was made, after their reconciliation, earl of Northumberland, as his uncle's heir but was imprisoned for life on rebelling again in 1095. Bishop Geoffrey's other nephews, Nigel and William, were given great estates in England by Henry I. William was made king's butler, and was father of William d'Aubigny ("de Albini"), first earl of Arundel (*see* ARUNDEL); Nigel was rewarded with the escheated fief of Geoffrey de la Guerche, of which Melton (Mowbray) was the head, and which forfeited lands in Yorkshire. Nigel's grandson William, a leader in the rising against King John, was one of the 25 barons of the Great Charter, and was captured fighting against Henry III. at the rout of Lincoln (1217). William's grandson Roger (1266–98), who was summoned to parliament by Edward I., was father of John (1286–1322), whose wife added Gower in South Wales and the Bramber lordship in Sussex to the great possessions of his house. Their son John (d. 1361) was father, by a daughter of Henry earl of Lancaster, of John, Lord Mowbray (*c.* 1328–1368), whose fortunate alliance with the heiress of Lord Segrave, by the heiress of Edward I.'s son Thomas, earl of Norfolk and marshal of England, crowned the fortunes of his race. In addition to a vast accession to their lands, the earldom of Nottingham and the marshalship of England were bestowed on them by Richard II., and the dukedom of Norfolk followed. (*See* NORFOLK, THOMAS MOWBRAY, 1st duke of.) His great grandson John, 4th and last duke was created earl of Warrenne and Surrey (1451). At his death (1475) his vast inheritance devolved on his only child Anne, who was married as an infant to Edward IV.'s younger son Richard (created duke of Norfolk and earl of Nottingham and Warrenne), but died in 1481.

The next heirs of the Mowbrays were the Howards and the Berkeleys, representing the two daughters of the first duke. Between them were divided the estates of the house, the Mowbray dukedom of Norfolk and earldom of Surrey being also revived for the Howards (1483), and the earldom of Nottingham (1483) and earl marshalship (1485) for the Berkeleys. Both families assumed the baronies of Mowbray and Segrave, but Henry Howard was summoned in his father's lifetime (1640) as Lord Mowbray, which was deemed a recognition of the Howards' right; their co-heirs, from 1777, were the Lords Stourton and the Lords Petre, and in 1878 Lord Stourton was summoned as Lord Mowbray and Segrave. The former dignity is claimed as the premier barony, though De Ros ranks before it.

MOWBRAY, HARRY SIDDONS (1858–1928), American artist, was born of English parents at Alexandria, Egypt, on Aug. 5, 1858. Left an orphan, he was taken to America by an uncle, who settled at North Adams, Mass. After a year at the U.S. Military academy at West Point, he went to Paris and entered the atelier of Léon Bonnat, his first picture, "Aladdin," bringing him to public notice. Other early canvases of high rank included "The Evening Breeze," "Scheherazade," "The Last Favorite." He was best known, however, for his mural paintings, and to these his later years were devoted. They included murals in the residences of F. W. Vanderbilt, J. Pierpont Morgan and Collis P. Huntington; the ceiling and walls of the library and decorations in the council room of the University club in New York city; mural paintings in the appellate court house, New York city; in the Federal court room, Cleveland; in the art gallery of Hon. Breckinridge Long, St. Louis; and in the church and Gunn Memorial library at Washington, Conn. He died on Jan. 13, 1928.

MOZAMBIQUE, a town of Portuguese East Africa, till 1907 capital of the province of Mozambique, and the seat of a Roman Catholic bishopric in the province of Goa, is in 15° 4′ S., 40° 44′ E., 7,157 m. from Southampton, and 175 m. from Ibo. The town occupies the whole of a small coral island at the mouth of Mossuril bay. The name Mozambique, used first to designate the island, was also given to the town and extended to the whole of the Portuguese possessions on the east coast of Africa. There are three forts, of which the principal, St. Sebastian, on the northern end of the island, was built in 1510 entirely of stone brought from Portugal. The harbour is deep enough to admit vessels drawing 28 ft. The channel is beaconed and lighted by buoys, and there is a lighthouse on Goa island. There is a milling establishment and an oil factory in the town. The Municipal council is appointed by the Government. In 1925, 1,669 ships entered and 1,689 left the port. There is a passenger pier. Malaria and bilious fever are prevalent in the rainy season.

The inhabitants, who number about 7,000, consist chiefly of Mohammedan natives of mixed descent speaking a dialect of the Makwa language. There are Parsee, Banyan, Goanese and Arab traders, and about 300 Europeans, besides half-caste Portuguese. The annual average value of the imports for the three years 1904–06 was £97,035, of the exports £71,636. The import trade is mainly with Great Britain and India, the chief articles being cotton, coloured shawls and hardware. The exports, of about 50,000 tons annually, are chiefly ground-nuts, a little rubber of inferior quality, sesame and other oil seeds and timber. Mozambique was discovered by Vasco da Gama in 1498. There was then a flourishing Arab town on the island, of which no trace exists. The history of the Portuguese town is closely identified with that of the province, for which *see* PORTUGUESE EAST AFRICA. Mozambique has been eclipsed by Lourenço Marques.

MOZARAB, a general term for persons not Arab by race who have assimilated themselves to the Arabs (Spanish *Mozárabe,* a corruption of the Arabic *Musta'rib,* coll. *Musta'riba*). It was applied by the Muslims in Spain to the Christian communities existing among them, in Cordova, Seville, Toledo and other large cities. The ancient liturgy used by the Christians of Toledo is commonly known as Mozarabic.

MOZART, WOLFGANG AMADEUS (1756–1791), Austrian composer, was born at Salzburg on Jan. 27, 1756. (In the baptismal register his name stands Joannes Chrysostomus Wolfgangus Theophilus [Lat. Amadeus, Ger. Gottlieb].)

He was educated by his father, Leopold Mozart, a composer with a high reputation as a violinist in the service of the archbishop of Salzburg. When only three years old he shared the harpsichord lessons of his sister Maria ("Nännerl"), five years his senior. A year later he played minuets and composed little pieces, some of which are still preserved. In 1762 Leopold Mozart took "Wolferl" and Nännerl on a musical tour, during the course of which they played before most of the sovereigns of Germany. The little Wolferl remained unspoilt by all the petting he received from royalty. At Vienna the emperor, Francis I., sat by his side while he played and called him his "little magician." When he slipped one day on the polished floor the archduchess Marie Antoinette, afterwards queen of France, lifted him up, whereupon he said, "You are very kind; when I grow up I will marry you."

Childhood and Youth.—In 1763 the whole family started on another tour. Wolferl now sang, composed and played on the harpsichord, the organ and the violin, winning golden opinions everywhere; but not enough money for more than bare necessities after the irreducible expenses of travel. In Paris they lodged at the Bavarian embassy, performing on a grand scale both there and at Versailles, where Wolferl's organ-playing was especially admired. Here also he published two sets of sonatas for the harpsichord and violin, having already composed several smaller pieces. In April 1764, Leopold Mozart took his family to England, where Wolferl astonished the royal family with his playing at sight and accompanied the queen in a song. He composed a symphony, published a third set of sonatas, dedicated to the queen; and wrote a tiny anthem (*Spruch*) for four voices, *God is our Refuge,* for presentation to the British Museum. (The autograph is numbered "Select Case C, 21 d.") Barrington contributed to the *Philosophical Transactions* for 1780 a paper on Mozart's prodigious talent as shown during his visit to London at eight years of age. In Sept. 1765 the family left England for the Hague, where, in March 1766, Wolferl made his first attempt at an oratorio, astonishing the Dutch as he had astonished the English, and playing with great effect, at Haarlem, on the largest organ in the world. In Sept. 1767 he paid a second visit to Vienna, and at the suggestion of the emperor, Joseph II., composed an opera buffa, *La finta semplice,* which, though acknowledged by the company for which it was written to be "an incomparable work," was suppressed by an intrigue. The archbishop of Salzburg thereupon commanded a representation of it in his palace, and gave Wolferl an honorary appointment as maestro di capella. Since this did not involve residence, Leopold Mozart took his son to Italy, in Dec. 1769, as the proper measure to complete a musician's education.

Wolfgang, now nearly 14 years old, received at Milan a commission to write an opera for the following Christmas. Arriving in Rome on the Wednesday in Holy Week, he went at once to the Sistine chapel to hear Allegri's famous *Miserere,* which afterwards he wrote down from memory, to the consternation of all who heard of the feat; for the composition was guarded as a mystery, and the singers were forbidden to transcribe it on pain of excommunication. Towards the end of June the pope made him a "cavaliere" of the order of "The Golden Spur," an honour which had some years previously been conferred on Gluck. Mozart prized it the more on that account, but soon gave up signing himself with the title, whereas the chevalier Gluck insisted on it to the end of his life. In July the Accademia Filarmonica of Bologna gave Mozart the degree of *compositore* in spite of a statute restricting this title to persons at least 20 years of age. His degree-exercise in strict counterpoint on the antiphon, *Quaerite primum,* is extant (Köchel's Catalogue, No. 86). His friendship with the learned padre, G. B. Martini (*q.v.*), was delightful to the boy and the sage, and it foreshadowed for Wolfgang what was afterwards to come to him from another spiritual father, "Papa Haydn." On Dec. 26, Wolfgang's new opera, *Mitridate Re di Ponto,* was triumphantly produced under his direction at Milan after a nerve-racking struggle with hostile intrigues. Mozart had been baulked of his hope to be allowed to set an opera by Metastasio; but the poetaster from Turin did his best; and the first rehearsal

settled all doubt as to the capacity of a German child of 14 to write an Italian opera and to control the orchestra of La Scala, the largest in Europe. The piece had a continuous run of 20 nights, a record for those times; and it established the boy as a master needing no apologies.

After this triumph, and after a concert-tour through many Italian cities, Wolfgang returned with his father to Salzburg, in March 1771, with large commissions for a dramatic serenata for the approaching marriage of the archduke Ferdinand, and an opera for La Scala, to be performed in 1773. The wedding took place at Milan on Oct. 21, and the serenata, *Ascanio in Alba,* was produced with an effect which eclipsed Hasse's new opera, *Ruggiero,* composed for the same occasion. The good Hasse prophesied: "This boy will cause us all to be forgotten." During the absence of Wolfgang and his father the good archbishop of Salzburg died; and in 1772 a successor was elected for whom nobody but the electors had a good word then or since. For his installation Wolfgang composed an opera, *Il Sogno di Scipione,* but the new prelate's interests were not intellectual; and before five years were past he made Salzburg a miserable place for musicians. The new opera for Milan, *Lucio Silla,* was produced at La Scala at Christmas, with a success equal to that of *Mitridate,* and it had a still longer run. Wolfgang was developing rapidly and beginning to create styles and forms that changed the nature of music. His opera buffa, *La Finta giardiniera,* produced Jan. 13, 1775, at Munich, tackles the action of an absurdly complicated play with unmistakable foreshadowings of the technique of *Figaro*. In March he set Metastasio's dramatic cantata, *Il re pastore.* Concertos, masses, symphonies and sonatas poured forth with a steady increase of power and resource. The *Missa brevis* in F (*see* MASS) is the last word in Neapolitan Church music, and the style of the symphonies and string-quartets of these years is full of wit and of terse formal devices. But these achievements did not earn money, and in 1777 Leopold Mozart asked the archbishop for leave of absence for a concert tour. The archbishop disapproved of "that system of begging." Wolfgang thereupon resigned his honorary appointment after furious protests from the archbishop; and on Sept. 23 started with his mother for Munich.

Manhood.—The results were not encouraging. Leopold discovered with surprise that a young musician of 21 could not make as much impression in palaces as an infant prodigy. Moreover, at Mannheim, where Stamitz (*q.v.*) had created a new standard of playing, Wolfgang not only imitated the Mannheim musicians but fell in love with Aloysia Weber, the daughter of the poorly paid prompter of the theatre. (Carl Maria von Weber, born 11 years later, was her cousin.) Leopold, dreading an improvident marriage, ordered his wife and son to start instantly for Paris, where they arrived on March 23, 1778. But in spite of the success of his Paris symphony (with its diplomatic initial *coup d'archet* and the unexpected pianissimo opening of the finale, which evoked an interruption of several minutes for applause), he found himself neglected by the aristocracy; and his mother fell seriously ill and died on July 3. After this catastrophe he left Paris in September and found Aloysia Weber cruelly changed towards him when he stopped at Mannheim. In June 1779 he returned to Salzburg and succeeded in inducing the archbishop to attach a salary of 500 florins to his "concertmeister's" appointment, with leave of absence in case he should be asked to write an opera elsewhere.

Two years later he was engaged to compose an opera for Munich for the carnival of 1781. The libretto was furnished by the abbate Varesco, the archbishop's court chaplain. On Jan. 29, 1781, the work was produced under the title of *Idomeneo, re di Creta* and made a great impression. It reveals Mozart's full powers of orchestration, vocal and choral style, accompanied recitative and nobly pathetic melody. In these respects it was incontestably the finest opera that had ever yet been placed upon the stage. Dramatically, it is not mature. Mozart, though profoundly influenced by Gluck in the accompanied recitative of the oracle-scene in the temple of Neptune, could as yet resist the temptations neither of coloratura singing nor of symmetrical form. And he had not yet learnt the art (and duty) of bullying his librettist. And now the archbishop realized that Mozart was an adornment to his servant's hall. On hearing of the success of *Idomeneo* he instantly summoned the composer to Vienna, where he was spending the season. Mozart soon found his position intolerable. Musicians of his standing were already becoming restive at being made to dine with flunkeys, but the archbishop's flunkeys copied their master's insolence. Mozart's salary was reduced from 500 to 400 florins, he had to pay his own travelling expenses, and he was forbidden to give concerts on his own account or to play anywhere but the archiepiscopal palace. Archbishop Hieronymus found himself omitted from the list of the emperor's summer guests and he quitted Vienna in disgust, sending his household to Salzburg, but leaving Mozart to find lodgings at his own expense. Thereupon Mozart resigned. The archbishop's language thereat was unprintable, but Mozart remained in Vienna in a house rented by his old friends, the Webers, vainly hoping for pupils in the dead season. One good thing we owe to the archbishop. Michael Haydn was also in his service and had been commissioned by him to write six duets for violin and viola. He fell ill after writing four and the archbishop refused to pay him unless all six were forthcoming. Mozart came to the rescue with two duets in his richest style; and Michael Haydn sent them in with his own. The archbishop showed no suspicion.

The emperor protected Mozart and commissioned him to write a German opera, *Die Entführung aus dem Serail,* which, on July 16, 1782, had great success in Vienna and afterwards at Prague. This great work was the first imperishable monument of the German *Singspiel* (or opera with spoken dialogues) as *Idomeneo* was the last living monument of the old Italian *opera seria.* Mozart had now mastered the art of bullying his librettist, whose chief characters he idealized to heroic proportions, while he himself exercised an extraordinary facility of comic rhyme and created the gigantic *buffo* character of Osmin.

On Aug. 16 Mozart married Constanze, the younger sister of Aloysia Weber, and the namesake of the heroine of *Die Entführung*. Much sour wisdom has been poured forth on this improvident marriage by biographers, who, accepting uncritically Mozart's steadfast creed of "Next after God, papa," are shocked by the fact that Constanze was not a good manager, and are disposed to see serious infidelity in the freedom of Mozart's manners with singers and actresses.

From the day of his marriage to that of his death Mozart was always in difficulties for lack of money. The happiness of Mozart's most private affairs is revealed to us by the exquisite quality of the works which he wrote especially for his wife; but of course these were the only works he could afford to leave unfinished! Life in the Mozart home could never have been comfortable, nor could its irregular hours have been good for children, such as Mozart's own, and his pupil, J. N. Hummel, who lived in his home, and who used sometimes to be roused at midnight to sing or play his master's latest piece while Frau Mozart gave him a glass of wine. But his children were devoted to his memory; and his widow afterwards married one Nissen, who spent untold efforts in collecting material for his biography and for a catalogue and canon of his works.

The court and nobility were kind, though not munificent, and Mozart had many friends. "Papa Haydn" told Papa Mozart that Wolfgang was the greatest musician he had ever seen or heard of; and that all the crowned heads of Europe would compete for his services if they could only be made to see his worth. But he had enemies also. His ability was terrifying and he was naively unconscious of the devastating sharpness of his criticisms. Salieri hated him, and laid up terrible odium for himself after Mozart's death, by having openly shown his dislike and baulking Mozart of a good appointment. Rumour accused him even of poisoning Mozart, and the slander is perpetuated in Rimsky-Korsakov's opera, *Mozart and Salieri.* Let us set against this the affection Beethoven and Schubert had for the poor old man, who sent for Moscheles in 1825 to make a death-bed statement in these words: "I did not poison Mozart."

Closing Years.—On Feb. 7, 1786, Mozart produced at Schönbrunn an exquisite little *Singspiel* in one act, *Der Schauspieldirektor,* and in less than three months followed it by *Le Nozze di*

Figaro. The emperor was afraid of Beaumarchais' subversive satire, but Mozart was able to assure his majesty that the abbé Da Ponte had made the libretto quite harmless. After an enthusiastic reception of *Figaro,* Mozart's enemies succeeded in so far spoiling his success that he declared he would never produce an opera in Vienna again. Fortunately, *Figaro,* like *Die Entführung,* was repeated with brilliant success at Prague, and Mozart there received a commission to write an opera for the next season, with a fee of 100 ducats. Da Ponte furnished a libretto, founded, not on Molière's *Festin de pierre,* but directly on Tirso de Molina's *Burlador de Sevilla* and entitled *Il Don Giovanni.* By Oct. 28, 1787, the whole was ready, except the overture, not a note of which was written. Yet the overture is the most elaborate Mozart had yet composed, and it was all written the night before the performance, while his wife kept him awake with coffee and amusing tales as he tossed page after page of the score to the copyists. The opera was produced on Oct. 29 with extraordinary effect, and the overture, though played without rehearsal, was as successful as the rest of the music. Michael Kelly, in his *Reminiscences,* has left a delightful account of the circumstances. Yet, when reproduced in Vienna, *Don Giovanni* was soon withdrawn in favour of Salieri's *Tarare*.

On returning to Vienna Mozart was appointed kammercompositor to the emperor, with a salary of 800 gulden. In April 1789 he accompanied Prince Lichnowski to Berlin, where King Frederick William II. offered him the post of kapellmeister, with a salary of 3,000 thalers (£450). Though most unwilling to quit the emperor's service, he informed him of the offer. "Are you going to desert me, then?" asked the emperor; and the good-natured Mozart remained, to starve. The emperor now commissioned Mozart to compose another Italian opera, which was produced on Jan. 26, 1790, under the title of *Così fan tutte*. The libretto, by Da Ponte, was designed to give Mozart unlimited opportunities for mock heroics. The public seem to have seen the point of Mozart's delicious three hours of parody, but the run of the opera was stopped by the emperor's death on Feb. 20. The well-meaning 19th century took *Così fan tutte* on a solemn estimate of the probability of its plot, and it did not come again into its rights until Richard Strauss produced it properly at Munich and inaugurated our better understanding of Mozart's irony.

In March, Schikaneder, the manager of a small suburban theatre, approached Mozart with a project for a fairy opera addressed cryptically to Freemasons, who were frowned upon by the empress, Marie Thérèse, and the Church, but of whose brotherhood Mozart was an enthusiastic member. As in the case of *Die Entführing,* he soon whirled Schikaneder off his feet and raised the fairy tale to sublime heights.

While he was working at *Die Zauberflöte* a stranger called on him, requesting him to compose a *Requiem* and offering to pay for it in advance. The stranger's behaviour was so mysterious that Mozart, who was already out of health, came to take him for a supernatural messenger of death. Meanwhile he received a commission to compose an opera, *La Clemenza di Tito,* for the coronation of the new emperor, Leopold II. at Prague. He carried out this work piece-meal, night and day, in travelling coaches and during rehearsals. The coronation took place on Sept. 6; the new empress called the opera "another German piggishness," but Metastasio's worst libretto had received better music than it deserved; and this was the swan song of opera seria. *Die Zauberflöte* was produced on Sept. 30 and had a splendid run. But the *Requiem* still remained unfinished; the stranger therefore made another appointment, paying a further sum in advance. Mozart put his greatest music into it, and became more and more convinced that he was writing it for his own death. When the stranger called the third time the composer was dead, and his terrified widow had induced Süssmayer to finish the score in an imitation of Mozart's handwriting. Süssmayer surely must have known how Mozart intended to carry out the *Lacrymosa,* of which he had only written seven bars. The rest of Süssmayer's work does him extraordinary credit. The mysterious messenger was afterwards found to be an emissary of a Count Walsegg, who wished to perform Mozart's *Requiem* as his own.

Mozart died Dec. 5, 1791, apparently from typhoid (which in Germany is called typhus) though he himself believed that he had been poisoned. Constanze broke down, and when she recovered and visited the churchyard his grave could not be identified.

Works.—The first period in Mozart's development must be taken seriously as beginning at the age of five and merging into the second somewhere about the age of 16 or 17. It was fortunate that the infancy of the sonata-forms (*q.v.*) coincided with the infancy of Mozart; for in no earlier or later epoch could his juvenile work have had so normal a relation to the musical world at large. The little pieces composed by Mozart in his fifth and sixth years show an unswerving progress in which every step is represented, and the same mistake is never made twice, nor is a form once mastered ever repeated mechanically. The violin sonatas, written in London and Paris at the age of seven, are full of inventiveness, and technically as competent as most contemporary works. Mozart's studies in strict counterpoint gave him the greatest mastery of choral music attained since Handel, and more than one movement of Church music, written before he was 15, deserves to take rank as a true masterpiece. There was a loss of freshness at the age of 15, especially in the numerous operas; but by this time the machine could run without effort, and the depths of the adolescent mind could mature in peace while the hand was reeling off coloratura arias. *Lucio Silla* is almost evenly divided between such automatic stuff and evidences that the boy of 17 was developing the cogency of a man. Some of its recitatives and choruses strike a solemn dramatic note hitherto undreamt of in stage music, except by Gluck. *La Finta giardiniera* contains Mozart's first concerted opera-finale and marks the beginning of his dramatic vitality, just as the masses in F and D, written in the same year, mark the close of his first period as a composer of Church music. But we must beware of trying to assign periods according to art-forms; for in every year of his life Mozart practised all art-forms at once; and his mastery depends neither on method nor on inspiration. Some early violin sonatas assigned by Köchel to his 13th year really belong (as Wyzlewa and Saint Foix have shown) to his adolescence, and are full of the romantic pathos of C. P. E. Bach and J. Schobert.

Idomeneo and Die Entführung.—*Idomeneo* is the only opera of Mozart in a form which could show the influence of Gluck. Its wonderful choruses and its mature orchestration and profound counterpoint are as far beyond Gluck's range as its formalities and hampered action are repugnant to Gluck's dramatic reforms. The problems of comic opera were far more suggestive to Mozart. In *Die Entführung* his exuberant music still needed (and to a slight extent received) pruning, but his dramatic genius, as shown in the part of Osmin, began to run away with his music instead of his music running away with the action. And his power of musical characterization was genuine, and not dependent on tagging each person with a mannerism. After *Die Entführung,* Mozart's record is a series of masterpieces, accompanied, but not interrupted by a running commentary of popular trifles, which often served him as studies. Almost every composition solves an art-problem, sometimes with the queerest materials. The répertoire of the modern organist contains, since Bach, no grander piece than the two fantasias which Mozart wrote for the barrel of a musical clock. Shortly before his death he wrote a beautiful adagio and rondo for the glass harmonica, in combination with flute, oboe, viola and violoncello, a perfect scheme which nobody else could have imagined. He wrote some effective processional music for two flutes, five trumpets and four drums; a beautiful adagio for two clarinets and three basset-horns (practically five clarinets), and a nice little sonata for bassoon and violoncello. His work in the larger instrumental forms is further discussed in the article SONATA FORMS.

Le Nozze di Figaro.—Mozart's later operas, from *Figaro* onwards, represent the nearest approach to a perfect art-form attainable in pre-Wagnerian opera. We cannot guess what he might have attained in serious opera had he lived to see the solemn triumphs of the French operatic stage in the austere sincerity of Cherubini and Méhul. We cannot doubt that he would have taught Beethoven to bully his librettist betimes, and that *Fidelio*

would not have stood in perilous and lonely splendour as an opera with a serious plot. But Mozart knew serious opera only as an Italian art form, which Gluck himself could not permanently rescue from the tyranny of singers. After *Idomeneo* he handled it only perfunctorily in *La Clemenza di Tito*. Comedy gave him full scope, and in *Figaro* he had the advantage of a libretto which was already a famous product of consummate stagecraft before it ever became an opera. Its absurdly complex intrigues do not worry the spectator, for no one attempts to follow them; but they keep every person on the stage in a state of excitement which is so idealized by the music that, while Beaumarchais' *Mariage de Figaro* has its place in literature, Mozart's *Figaro* is one of the greatest classics in all music. The subject is a social satire; but Mozart lives in Cloud-cuckoo-land. His characters are as irresponsible as fairies. Theirs is the world described by Lamb—the Utopia of gallantry, where pleasure is duty and the manners perfect freedom. The countess, however, is human. Producers destroy the purposes of Beaumarchais and of Mozart when they make her seem no longer young. It is only two or three years since she was Rosina in *Le Barbier de Séville;* the young Cherubino is in love with her; and the Count's intrigues have no excuse.

Don Giovanni.—In *Don Giovanni* Mozart rises, not only in the music of the ghostly statue, but also in that of Donna Anna and Donna Elvira, to heights that must be called sublime; the comedy of gallantry is in conflict with real human issues. Donna Anna's cadences are conventional when her grief has become a memory that stands between her and her lover; but at the first shock of her father's death her music is as tragic as Beethoven could have made it, cadences and all. Elvira, Don Giovanni's deserted wife, ought, like the Contessa in *Figaro,* to be represented as quite young. She enters in search of her vanished husband and sings Italian formulas which Wagnerian critics tell us are inadequate for the expression of her sorrows. Look at the *sforzando* in the second violins at the words *Ah se ritrovo l'empio*. Mozart is telling us that this inexperienced girl has not as yet come to any determination more serious than the wish to scratch Don Giovanni's eyes out. As soon as his character is revealed to her in Leporello's comic aria of the "catalogue," she determines that others at all events shall not suffer as she has suffered; and from that moment she becomes majestic. In the second act she weakens and Don Giovanni fools her to the top of her bent. Yet Mozart realizes better than Da Ponte a consistent development of her character. Her last confession of weakness, *Mi tradi,* was, like *Non mi dir,* inserted by Mozart afterwards. Both arias may be omitted; but at all events we need not make nonsense of Elvira's behaviour by putting *Mi tradi* into the first act as her second utterance, in immediate response to Leporello's catalogue aria! The final impression made by a well-conceived performance of *Don Giovanni* is of something grander than comedy. Da Ponte's stage directions should be respected; Don Giovanni should be carried off by little Italian pantomime devils, and the music should be allowed to rise undisturbed by the efforts of pantomime scenery to follow it. The beautiful final scene afterwards added by Mozart should be omitted, though with regret. Don Giovanni's indomitable courage should be that of a nobleman; and there should be no buffoonery in the comic figures of Leporello, Masetto and his fairylike Zerlina, whom Elvira snatches from the wicked hero's toils.

Die Zauberflöte and the Requiem.—In *Così fan tutte,* Da Ponte's wit and Mozart's irony were above the heads of musicians before Richard Strauss; but this work is now recognized as a subtle parody that constantly totters on the verge of reality. In *Die Zauberflöte* Mozart is in a masonic lodge of a degree higher than is known on earth. Though Mozart's head was in the heavens, his feet were very firmly planted on the stage, and he and Schikaneder understood each other perfectly and united to achieve something unique in opera; combining the gorgeousness of a pantomime with the solemnity of a ritual and the contemporary interest of a political satire.

From the solemnity of freemasonry there is but one step to that most pathetic of unfinished monuments, Mozart's *Requiem.* Its finished portions contain the most sublime Church music between Bach and the *Missa solemnis* of Beethoven. Süssmayer's completion is so well designed that even the slightness of his themes has the effect of a gesture of reverence and love. The return of the music of *Te decet hymnus* at the words *Lux aeterna,* which enables Süssmayer to end with ten pages of authentic Mozart is placed like a stroke of genius (though Mozart is reported to have contemplated an independent final number); while the latter part of the *Lacrimosa,* though not in Mozart's handwriting, must surely have been dictated by him. The instrumentation of Mozart's skeleton score is almost entirely ascertainable by the rules of his scheme; but that of the supplied numbers goes wrong at once. In the *Requiem,* as in some wonderful polyphonic designs before it, Mozart was forming a new style which might have transcended everything we know of him. Nevertheless, what he has left us is unique, and the intelligent love of Mozart's music is a liberal education in the meaning of art.

The Mozart Catalogue.—Mozart's extant works are catalogued by Köchel in 626 items, beginning with minuets written at the age of four and ending with the *Requiem.* In addition to these 626 there are many tantalizing fragments. Köchel's work was very necessary and, with corrections from the researches of Wyzlewa and Saint Foix, it remains necessary to-day, for no composer has had so many spurious works thrust upon him as Mozart. The famous "Twelfth Mass" and four others in Novello's edition ought never to have deceived good musicians. They were the work of one Zulehner, whose avowed compositions remain unpublished in the archives of Schott at the present day. Nor are such deceptions unknown in the 20th century. A concertante for four wind instruments went round Europe in 1905 as a long-lost work written in Paris in 1778.

On the other hand, five little divertimenti for two clarinets and bassoon were, in 1911, found to be Mozart's work in his ripest manner as soon as two spurious and hideous horn-parts were removed. A seventh violin concerto appeared in Nov. 1907 and, though inferior to the earlier ones, is in every detail exactly in keeping with Mozart's progress in 1777, its alleged date.

(D. F. T.)

MOZDOK, a town of Russia, in the North Caucasian Area in 43° 46′ N., 44° 38′ E., on the Terek river. Pop. (1926) 14,008.

MTSENSK, a town of Russia in the Orlov province in 53° 17′ N., 36° 33′ E., on the navigable Zusha river, near its confluence with the Oka. Pop. (1926) 10,045.

MTSKHET, a village in the Georgian S.S.R. in 41° 54′ N., 44° 42′ E., 13 m. N. of Tiflis, with which it is linked by rail. It stood at the outlet of the old Lake of Karthelia and was the residence of the Georgian kings in the 4th and 5th centuries. It is at the junction of the main routes from the Darial gorge through the Aragva valley and from the Caspian and Black seas through the Kura and Rion basins.

MUCH WENLOCK, market town, Wenlock municipal borough, Wrekin parliamentary division, Shropshire, England, 163 m. N.W. from London on the G.W. railway. (For history of the priory *see* WENLOCK.) It lies at the north end of Wenlock Edge, a low escarpment. There are beautiful remains of the priory church, chiefly Early English; but with a chapter-house of ornate Norman work. The prior's house, still inhabited, is a remarkable specimen of 15th-century work, adjoining and incorporating remains in earlier styles. The parish church of Holy Trinity is of mixed styles from Norman onwards. There is a picturesque half-timbered guild-hall (1589), with rich carved oak.

MUCIC ACID, a dibasic acid obtained as a crystalline powder melting at 213° C, insoluble in alcohol and sparingly soluble in water. Mucic acid, $CO_2H{\cdot}(CHOH)_4{\cdot}CO_2H$, is obtained by the oxidation of milk, sucrose, galactose, and most varieties of gums. The manufacture of mucic acid is practised at Eureka, Mont., where larch sawdust is hydrolysed with formation of galactose, this sugar being then oxidized with nitric acid, when mucic acid is isolated by concentrating the acidic solution. Mucic acid is used as a substitute for cream of tartar in baking powders and other effervescent preparations. On dry distillation mucic acid yields pyromucic or furoic acid, $C_4H_3O{\cdot}CO_2H$ (*see* FURFURANE), a solid melting at 132° C and resembling benzoic acid (*q.v.*).

MUCKERS, the nickname given to the followers of the teaching of Johann Heinrich Schönherr (1770–1826) and Johann Wilhelm Ebel (1784–1861). Shönherr was educated at the University of Königsberg, where the theological faculty was strongly rationalistic in tendency. Dissatisfied with this philosophy, Schönherr developed, with the aid of the Bible, a philosophy of his own and became the prophet of a dualistic theosophy very similar to Gnosticism. Schönherr died in 1826 but among his converts was Ebel, who was appointed pastor in Königsberg. In the pulpit Ebel was orthodox, but he taught Schönherr's doctrines privately to a select circle. In 1827 he was joined by Heinrich Diestel, also a Lutheran pastor of Königsberg. Together they became father confessors to a wide circle of fashionable people. But because of their peculiar teaching, which involved the minute regulation of the intercourse of married people, scandal was inevitable. In 1835 Count Finckenstein, an initiate, accused the pastors of immorality. The matter was placed before the consistory, whose proceedings became famous as the *Königsberger Religionsprozess* (1835–1841), which ended in the deprivation of both Ebel and Diestel.

See J. L. Mombert, *Faith Victorious* (1882); Hepworth Dixon, *Spiritual Wives* (1868); and, more especially, the article on Schönherr, by P. Tschackert, in Herzog-Hauck, *Realencyklopädie* (3rd ed., Leipzig, 1906), xvii. 676.

MUCUNA, a genus of twining plants, belonging to the family Leguminosae, and natives of the tropics. *M. pruriens* is popularly known as cowhage or cowitch, a corruption of the Hindu *Kiwach.* It is a tall annual climber with large dark purple pea-like flowers, and golden-brown velvety pods, the hairs or bristles on which often raise blisters on the skin. It is common in the tropical regions of India, Africa and America, and the hairs on the pod have long been used in medicine as a vermifuge. A variety of this plant is the Florida velvet bean, used as a fodder-plant.

MUDANIA (anc. *Apamea Myrlea*), a town of Asia Minor, on the south coast of the Sea of Marmora, and the port of Brusa. It is connected with Brusa by road and rail, and with Constantinople by steamers. Olive oil is produced. Pop. (1927) 13,838.

MUDEJAR, in architecture, the mixed style which was developed in Spain during the middle ages by the merging of Christian and Mohammedan traditions, especially applied to the style developed after the Christian conquest, by Mohammedans working under Christian supervision. The style affected particularly brick work, tile work and carpentry, in the detail treatment of which, Moorish forms and methods persisted long into the Renaissance. Good examples of the style are the tower of S. Andres at Calatayud (probably 15th century), the dome of Saragossa cathedral (*c.* 1412, present form 1500–20), the chapter room at Tordesillas (*c.* 1363) and many elaborate wooden ceilings, known as *artesonados.* For a thorough discussion *see* G. King, "Mudejar," *Bryn Mawr Notes and Monographs,* viii. 1927.

MUDFISH, a name given to several very different fishes, including the North American bowfin (*q.v.*) and the three living genera of lung-fishes (*q.v.*).

MUDIE, CHARLES EDWARD (1818–1890), English publisher and founder of Mudie's lending library, was born at Chelsea on Oct. 18, 1818, the son of a secondhand bookseller and newsagent. In 1840 he established a stationery and bookselling business in Bloomsbury, London. In 1842 he began to lend books. This department proved so successful that in 1852 he moved his "Select Library" to larger premises in New Oxford street, London. In 1860 these premises were substantially enlarged, and branches of the business established, and in 1864 "Mudie's" was converted into a limited company. Mudie himself died on Oct. 28, 1890.

MUD-PUPPY, the American name for *Necturus maculatus,* a water-breathing newt allied to Proteus (*q.v.*). *See* Amphibia.

MUFFLE FURNACE: *see* Furnaces, Metallurgical.

MUFTĪ, a consulting canon-lawyer in Islām, who, upon application, gives *fatwās* or legal opinions on points of the sacred law (*see* Islamic Law). These are asked and given in strictly impersonal form, but the cadi, or judge, then applies them to the case and decides in accordance with them. In theory, any learned man whose opinion is respected and whose advice is sought can give fatwās. But generally in a Muslim state there are muftīs specifically appointed by the government, one for each school of law in each place. In Turkey the chief muftī of Constantinople, with the title of Shaykh al-Islām, was the head of the ecclesiastical side of the state, while the grand vizier was at the head of secular matters; but his office was abolished in 1924 by the Turkish Republic. The use of the word for plain or civilian clothes worn instead of uniform is originally Anglo-Indian. It may have been suggested by the loose flowing robes of the "muftī."

Bibliography.—(Chap. v.); De Slane's trans. of Ibn Khaldūn's *Prolégomènes,* I. lxxviii. 447 *seq.;* Sir Charles Eliot, *Turkey in Europe* (chap. V.); art. "Shaikh al-Islām" in the *Encyclopaedia of Islam.*

MUG, a cylindrical drinking-vessel with or without a handle, made of earthenware or metal. The handle, also, makes it a convenient cup for small children, and a silver mug is frequently a christening gift to a child. (*See* Drinking Vessels.)

MUGGER (*Crocodylus palustris*), also called the marsh crocodile, is the best-known Indian species of crocodile. In times of drought it will undertake long migrations overland and has even been known to invade towns. (*See* Crocodile.)

MUGGLETON, LODOWICK (1609–1698), English sectarian, was born in Bishopsgate street, London. His father was a farrier, but he himself was bred to be a tailor. In 1651 he began to have revelations, and to proclaim himself and his cousin John Reeve, whose journeyman he was, as the two witnesses mentioned in Rev. xi. 3. In 1652 they put out their "commission book" under the title *The Transcendent Spirituall Treatise.* An exposition of their doctrines was published in 1656 under the title of *The Divine Looking-Glass.* Among other views (besides the doctrine of the divine mission of the authors) this work taught that the distinction of the three persons in the Trinity is merely nominal, that God has a real human body, and that He left Elijah as His vicegerent in heaven when He Himself descended to die on the cross. Muggleton's opinions gained some notable adherents, but also called forth much opposition. In 1653 he was imprisoned for blasphemy, and twice (1660 and 1670) his own followers temporarily repudiated him. His attack on the Quakers drew forth William Penn's book, *The New Witnesses proved old Heretics* (1672). In 1677 Muggleton was tried at the Old Bailey, convicted of blasphemy, and fined £500. Reeve died in 1658; Muggleton in 1698.

His collected works, including the posthumous *Acts of the Witnesses,* were published in 1756; and in 1832 some 60 Muggletonians subscribed to bring out a new edition of *The Works of J. Reeve and L. Muggleton* (3 vols.). Even as late as 1846 *The Divine Looking-Glass* was reprinted by members of the then almost extinct sect. *See* A. Jessopp, *The Coming of the Friars* (1888); G. C. Williamson, *Lodowick Muggleton* (1919).

MUGWORT, a plant name given to *Artemisia vulgaris,* found in Great Britain and widely naturalized in the United States and Canada; it is sometimes given also to *A. Absinthium* (wormwood, absinthium). In North America the name is applied to numerous herbaceous species of *Artemisia* native to the Great Plains region and westward, the shrubby species of the arid districts, as *A. tridentata,* being usually designated sage-brush. In Great Britain the crosswort (*Galium cruciatum*) is sometimes called mugwort. (*See* Galium.)

MUGWUMP, in American political slang, a name applied to any independent voter, and especially to those independents in the Republican Party who refused to support James G. Blaine, when nominated by that party for the presidency in 1884; as since adopted in England it usually means one who stays neutral and votes for no party. Originally "mugwump" (*mogkiomp*) was a North American Indian word, in the Massachusetts dialect of the Algonquian, meaning "great man" (*mogki,* great; *omp,* man); and in New England it was used of self-conceited politicians.

MUHAMMAD: *see* Mohammed.

MÜHLBERG, a town of Germany, in Prussian Saxony, on the left bank of the Elbe, 8 m. below Riesa. Pop. (1925) 3,540. It manufactures bricks, baskets and matches. Mühlberg is famous for the victory gained here, in 1547, by the emperor Charles V. over the elector of Saxony, John Frederick.

MUHLENBERG, HENRY MELCHIOR (1711–1787), German-American Lutheran clergyman, was born in Einbeck, Hanover, Sept. 6, 1711. When he was 12 years old, his father's

death forced him to assist in the family's support. Nevertheless he entered the University of Göttingen in 1735, and in 1738 he went to Halle, where he finished his theological studies and was a devoted worker in the Franckesche Stiftung, which later served as a partial model for his great-grandson's community at St. Johnland, Long Island. He was deacon at Grosshennersdorf, in Upper Lusatia, in 1739–41. In 1742, in reply to a call from the Lutheran churches of Pennsylvania, he went to America, stopping in England on the way further to qualify himself. Muhlenberg occupied himself more particularly with the congregation at New Providence (now Trappe) though he was practically overseer of all the Lutheran churches from New York to Maryland. In 1748 he organized the first Lutheran synod in America. He married in 1745 Anna Maria Weiser, daughter of J. Conrad Weiser, a well-known Indian interpreter. Throughout the Revolutionary War he and his sons were prominent patriots. He died at Trappe Oct. 7, 1787.

See W. J. Mann, *Life and Times* (Philadelphia, 1887); also various magazine articles and the biographical tale, *An Eagle of the Wilderness* (1924) by Margaret R. Seebach.

MUHLENBERG, JOHN PETER GABRIEL (1746–1807), American preacher and soldier, son of H. M. Muhlenberg (*q.v.*), was born at Trappe, Pa., on October 1, 1746. With his brothers he was educated in Germany. He entered the Lutheran ministry, had charge of churches at New Germantown and Bedminster, N.J., and after 1772 of a church in Woodstock, Va., and there in 1775 raised a German regiment, of which he was made colonel; in Feb. 1777, he became a brigadier-general in the Continental army. He took part in the battles of Brandywine, Germantown and Monmouth, and at Yorktown commanded the first brigade of light infantry. After the war he removed to Pennsylvania. He was a representative in Congress in 1789–91, in 1793–95, and in 1799–1801. In 1803 he became collector of the port of Philadelphia. He was a friend of Thomas Jefferson and of James Monroe.

See *Life* by Henry A. Muhlenburg (Philadelphia, 1849).

His brother, Frederick Augustus Conrad Muhlenberg (1750–1801), was pastor of the Christ (or Swamp) German Lutheran church of New York city from 1773 to 1776. In 1779–80 he was a member of the Continental Congress, and in 1789–97 was a member of the national House of Representatives, of which he was speaker in 1789–91 and 1793–95. On April 29, 1796, as chairman of the committee of the whole, he cast the deciding vote for the laws necessary to carry out Jay's treaty.

MUHLENBERG, WILLIAM AUGUSTUS (1796–1877), American philanthropist and Protestant Episcopal clergyman, was born in Philadelphia on Sept. 16, 1796, and graduated at the University of Pennsylvania in 1814. While at St. James's church in Lancaster, Pa., he wrote *A Plea for Christian Hymns* (1821), drew up for his own parish *Church Poetry* (1823), and was a member of the committee from the general convention which compiled an adequate collection of psalms and hymns, thus preparing the way for greater flexibility in the service. During his rectorship at St. George's, Flushing, L.I., he founded the Flushing institute in 1828, which developed after a time into St. Paul's college, and which was probably the first Protestant Episcopal school in the United States. The Church of the Holy Communion in New York city, a "free church" built in 1844–45 by his sister Mrs. Mary Rogers, he made a pioneer in the practical Christianity to which his later years were devoted. In addition to numerous parish activities he founded there the first American order of Protestant Episcopal deaconesses, the Sisterhood of the Church of the Holy Communion, which was formally organized in 1852. As a result of the work of the Sisters he established what he called his "hospital-church," St. Luke's in 1858. St. Johnland, his "church village" begun on Long Island in 1866 as an embodiment of Evangelical brotherhood, was designed to better the condition of the working class in general but particularly to provide healthy shelter for children and indigent old people. He died in New York city on April 8, 1877.

Anne Ayres, who was closely associated with him as "First Sister," described his life and work (1880); and W. W. Newton is the author of another biography (1890).

MÜHLHAUSEN, a town of Germany, in the Prussian province of Saxony, on the right bank of the Unstrut, 25 m. N.N.W. of Gotha by rail. Pop. (1925), 35,955. Mühlhausen is one of the oldest towns in Thuringia, and is said to have been fortified in 925. Its early importance is shown by the grant of privileges made to it by the German King Henry I., and by the diet held here in 1135. The Teutonic order established itself at Mühlhausen in 1200. During the Reformation period Mühlhausen became one of the chief seats of the Anabaptists. In 1802 it lost its independence and passed to Prussia, in 1807 it was attached to the kingdom of Westphalia, but in 1815 it again became Prussian. It consists of a new and an old town, and has numerous old churches and towers. The churches of St. Mary and of St. Blasius, date respectively from the 14th and the 12th century; the town hall is also a fine mediaeval structure. The chief industries are the spinning and weaving of wool and cotton. Other manufactures include machinery, soap, hosiery and furniture.

MUIR, JOHN (1810–1882), Scottish orientalist, was born on Feb. 5, 1810, in Glasgow, was a servant of the East India company from 1829 to 1853. He had a distinguished career in India. In 1862 he endowed the chair of Sanskrit in the University of Edinburgh, and was the main agent in founding the Shaw fellowship in moral philosophy. He died on March 7, 1882. Muir's most important work is his *Original Sanskrit Texts* (5 vols., 1858–70), of the utmost importance for the study of the Vedic age.

MUIR, JOHN (1838–1914), American naturalist and writer, was born at Dunbar, Scotland, April 21, 1838. His boy life there and on a backwoods farm in Wisconsin is delightfully told in his *Story of My Boyhood and Youth* (1913). Although both places increased Muir's inherent love of nature, he also had marked inventive genius and enjoyed the rush and turmoil of factory and city life. After he left the University of Wisconsin an accident which made him fear his eye was "closed for ever to all God's beauty" caused him to start on the long series of wanderings described in *A Thousand-Mile Walk to the Gulf* (1916); *My First Summer in the Sierra* (1911); *The Cruise of the Corwin* (1917) and *Steep Trails* (1918). The huge and spectacular forces of nature attracted him always—the pure air of the upper Yosemite, the majestic sequoia trees of California, the mighty glaciers of Alaska, to one of which his name was given; and in his letters and finished work he extols them in rhythmical prose. When he first started his study Muir had no intention of writing; after his marriage, April 14, 1877, to Louie Wanda Strentzel he devoted himself for a number of years to horticulture; at the end of his life he was working hard to put into shape the material he had accumulated, sufficient, he declared, for a dozen volumes. To his efforts are largely due the establishment of the Yosemite and other areas as national parks, and to a certain extent the national conservation policy. Muir died at Los Angeles (Cal.) Dec. 24, 1914.

See *Writings* (1916–24), a series which includes the *Life and Letters of John Muir* by the editor, W. F. Badé, and S. H. Young's *Alaska Days with John Muir* (1915).

MUIR, SIR WILLIAM (1819–1905), Arabic scholar, brother of the Sanskrit scholar, was born at Glasgow on April 27, 1819. He went out to India in 1837, and in 1865 became foreign secretary to the Indian Government. In 1867 he was knighted (K.C.S.I.), and in 1868 he became lieutenant-governor of the North-West Provinces. In 1874 he was appointed financial member of the Council, and retired in 1876, when he became a member of the Council of India in London. Through his help, the central college at Allahabad, known as Muir's College, was built and endowed. Muir was principal of Edinburgh University from 1885 to 1903. He died at Edinburgh on July 11, 1905.

His chief books are a *Life of Mahomet and History of Islam to the Era of the Hegira* (4 vols., 1858–61); *Annals of the Early Caliphate* (1883); *The Corân: its Composition and Teaching*; and *The Mohammedan Controversy*, a reprint of five essays published at intervals between 1885 and 1887.

See a notice by C. J. Lyall in the Royal Asiatic Society's *Journal* (1905).

MUIRHEAD, JOHN HENRY (1855–), British philosopher, was born in Glasgow, and educated at Glasgow academy and university, and at Balliol college, Oxford. He held professorships at Glasgow, London and Birmingham universities, and was then appointed Mills professor of philosophy in the University of Canada.

He has published several translations from the classics; many philosophical works, including *Philosophy and Life* (1908); *German Philosophy in Relation to the War* (1915), *Social Purpose* (with Hetherington, 1918); *Life and Philosophy of Edward Caird* (with Sir Henry Jones, 1921); and many articles. He also edited *Contemporary British Philosophy* (1924–25).

MUKADDASI[1] [the appellation of Shams ad Din Abu Abdallah Mohammed ibn Aḥmad] (*fl.* 967–985), Arabian traveller, author of a *Description of the Lands of Islam.* His descriptions rest on extensive travels through a long series of years. His first pilgrimage was made at the age of 20 (in A.H. 356=A.D. 967), but his book was not published till A.H. 375 (A.D. 985–986), when he was 40 years old.

The book became known in Europe through the copy brought from India by Sprenger, and was edited by M. J. de Goeje as the third part of his *Bibliotheca Geographorum Arabicorum* (Leiden, 1877). *See* also the English translation (unfinished) by G. S. A. Ranking and R. F. Azoo, in *Bibliotheca Indica,* New Series, Nos. 899, 952, 1001 (Bengal Asiatic Society, 1897–1901); Muḳaddasi's Syrian chapter has been separately translated and edited in English by Guy Le Strange (London, Palestine Pilgrims Text Society, 1886); in German by J. Gildemeister in *Zeitschrift des deutschen Palästina-Vereins,* vol. vii. (1884).

MUKDEN, the capital of Fengtien province, the seat of Government of the "Three Eastern Provinces," *i.e.,* Manchuria, and the ancestral capital of the Manchu Dynasty which ruled China from 1644 to 1911 (41° 51′ N. and 123° 25′ E.). It is known to the Chinese as Fengtien or Shêngking ("Abundant capital"). It is situated on the Hun-ho tributary of the Liao-ho, where the broad basin of central Manchuria contracts to a relatively narrow corridor between the east Manchurian Highlands and the Jehol hills which prolong the Mongolian Plateau almost to the coast. Mukden therefore controls the main north-south route which traverses this Liao corridor and the still narrower coastal sill giving access to the north China plain. Moreover the valley of the Upper Hun-ho, which here debouches on to the lowland, affords one of the chief routes through the east Manchurian Highlands. The strategic and focal significance of its position was realized at an early stage. In the 12th century it was the northernmost of the three capitals of the Empire of the Kin Tatars (Golden Horde), originally from the steppes of northern Manchuria. About the same period Aisiu Goro, from whom ultimately descended the Manchu dynasty, had his capital in the neighbourhood of the Chang-pai-shan mountains, north of the Korean peninsula. In the early 17th century his descendant Nurhachu, for the purpose of organizing and uniting the various Manchu tribes and with a view to the conquest of China, moved his capital down to the plain of the Liao-ho, towards the Chinese frontier. Mukden was then known as Shêngking and proved an admirable organising base for the conquest of China. In 1644 when the Manchus supplanted the Mings on the Imperial throne the capital was transferred to Peking. Shêngking, however, retained its prestige as the older capital of the reigning dynasty; the treasures of the royal house were deposited in its Palaces and the tombs of the earlier Emperors (particularly the mausoleum of Tatsung d. 1644 at Peilung, *i.e.,* North Mausoleum, about four miles from the city) are among the most famous monuments of China. In 1658 the provincial government of Fengtien was established and the city became known by its present name of Fengtien (Mukden).

In the period of struggle between Russia and Japan for dominance in Manchuria, Mukden was inevitably one of the key positions. It was for a time a Russian stronghold and was the scene of the protracted "Battle of Mukden" which lasted from February 19th to March 10th, 1905, when the city fell to the Japanese. Since the Russo-Japanese War the Japanese concession in Mukden has been one of their chief bases for the exploitation of South Manchuria, but it has also been the seat of government of the Chinese "Viceroy" of the three Manchurian provinces (Fengtien, Kirin and Heilungkiang). The relationship of this official to the Japanese on the one hand and the various parties contending for power in China Proper on the other has been for several years, and still is, one of the crucial factors in Chinese politics. During the Civil War (1924–27) Chang Tso-lin, the "Mukden War-Lord" governed Manchuria as virtually an independent country, from which he advanced, as the Manchus had done before him, to dominate the government of Peking. As a result of the advance of the Nationalist armies to the capital in 1928 and the dramatic death of Chang Tso-ling on his retreat to Mukden, the status of Manchuria has now somewhat altered. The position at the conclusion of 1928 was that the "War-Lord's" son, Chang Hsueh-liang, had given his adhesion to the Nanking Government and was one of its 16 State Councillors, but retained control over a separate sphere of administration in Manchuria.

As a focus of trade and industry Mukden reflects the remarkable economic development of Manchuria during recent years. The natural advantages of its site and its central position in relation to China on the one hand and the Japanese sphere in Korea and Kwantung on the other have made it the chief centre of the rapidly expanding railway system of South Manchuria. It is the central junction of the South Manchurian Railway where the main north-south line from Changchun (linked with the Chinese Eastern Railway) to Dairen in the Kwantung Leased Territory is connected with the Mukden-Antung-Korean system, and where too a short line runs to the Fushun coalfield. With China Proper it is connected by the Peking-Mukden (Chinese Government) Railway, recently continued north-eastwards to Hailung and ultimately to reach Kirin. Mukden lies near the junction of the rich agricultural Plain of South Manchuria with the forested highlands on the east and their resources are becoming increasingly available by the good system of communications. The chief crops of the plain are soya beans, grains, kaoliang and sugar-beet, along the S.M.R. zone, while the hills furnish forest products of various kinds, and other raw materials such as furs and hides reach Mukden from the North. In comparatively close proximity to the city are the Fushun coalfield, at present the most productive in all China, and the smaller Yentai field. Upon this varied basis of production many manufacturing industries have been developed in recent years. These include flour-mills, oil mills, tanneries, paper mills, soap factories and soy manufactures, while the expansion of the road system is making Mukden the headquarters of numerous transport companies, with good prospects for the motor industry. The railways and the Mukden Government Arsenal have created a strong demand for engineering material and Mukden has the beginnings of an important iron industry in the Ta Yeh works.

Mukden is the chief educational centre of South Manchuria, and its higher institutions include colleges established under Japanese, Chinese and missionary auspices, notably the North-Eastern University and the Mukden Medical College (Presbyterian Mission) which has done notable work in combating the bubonic plague, at times a serious menace to Manchuria.

Mukden now consists of three parts:—the old city, containing the Imperial Palaces and the Chinese Government Offices, surrounded by a brick wall about 30 feet high and four miles in circumference; the New Town or Japanese concession, which is the property of the South Manchurian Railway and laid out on a grand scale with wide macadamised roads, squares and parks; and an intermediate commercial quarter. The road system has been much improved; an electric-tram route under municipal control runs between the West Gate of the old city and the borders of the Japanese concession and a motor-omnibus service—a joint Chinese-Japanese enterprise—links the city with the South Manchurian Railway station. The Post Office estimate of the population of the Mukden administrative area (hsien) is 773,846 and the census of 1926 returned that of the native city at 245,315. (*See* MANCHURIA.)

MULA, a town of eastern Spain, in the province of Murcia; on the left bank of the Mula, a small right-hand tributary of the Segura. Pop. (1920), 12,319. The Sierra Espuña rises on the south to a height of nearly 5,200 ft. About 4 m. E. are two

[1]Al Muḳaddasi="the Jerusalemite."

groups of houses known as the Baños de Mula, with warm sulphurous springs.

MULATTO, a person one of whose parents is of a white race and the other a negro. In Latin America such half-breeds are sometimes called *mestizos* (*q.v.*).

MULBERRY, botanically *Morus* (family Moraceae), a genus of 12 species growing in the temperate regions of the northern hemisphere and in the mountains of the tropics. They are deciduous trees or shrubs with alternate, toothed, often three-lobed leaves and unisexual flowers in catkin-like inflorescences. The black mulberry (*M. nigra*), a native of western Asia, spread westwards in cultivation at an early period; it was cultivated by the Greeks and Romans, and in northern Europe by the 9th and 10th centuries. Up to the 15th century it was extensively grown in Italy for rearing silkworms, but has since been superseded by *M. alba*. It is now mainly cultivated for its oblong purplish-black fruit. The mulberry succeeds as a standard in the warmer parts of England, especially in sheltered situations, but in the north of England and the less favoured parts of Scotland it requires the assistance of a wall. The tree succeeds best in a rich, deep, and somewhat moist loam, but grows well in any good garden ground. It is usually propagated either by cuttings or layers. The mulberry may be grown in pots, and gently forwarded in an orchard house, and under these conditions the fruit acquires a richness of flavour unknown in the fruit ripened out of doors.

The white mulberry (*M. alba*), so called from its nearly white fruit, is the one mainly employed in silkworm culture. It is a native of China and has been cultivated from the earliest times in Asia and since the 12th century in Europe, especially in the Mediterranean region. There are many varieties, among which the Philippine mulberry (var. *multicaulis*) is perhaps most highly esteemed. The Indian species, *M. indica* (not to be confounded with *Morinda citrifolia*, a tree of the family Rubiaceae, sometimes also called Indian mulberry), is also cultivated for the same purpose.

The North American red mulberry (*M. rubra*) is the largest of the genus, often reaching a height of 70 ft. It produces dark red berries much inferior in flavour, however, to those of *M. nigra*. Both the white and the red mulberry have been grown in the eastern United States since colonial times and both have sparingly escaped from cultivation.

Broussonetia papyrifera, a member of a closely allied genus, is the paper mulberry, a native of Burma, China and Polynesia, and widely cultivated in Japan, where the bark is used for paper-making. The Tapa-cloth of the South Sea Islands is also made from it. The plant is a shrub or small tree with large mulberry-like lobed or entire hairy leaves. Several forms are cultivated, differing chiefly in the shape of the leaves. The paper mulberry, often planted for ornament in the south-eastern United States, has run wild in various localities from New York to Florida.

MULCAHY, RICHARD JAMES (1886–), Irish politician, was born in Waterford, and began his career in the engineering department of the Dublin General Post Office. He took part as a lieutenant in the Irish rebellion of 1916, and was afterwards interned in Frongoch. In Dec. 1918 he was returned as Sinn Fein M.P. for the Clontarf division of Dublin and retained his seat until 1922. He played a prominent part with Michael Collins in the reorganization of the Irish Volunteers, of which he had become chief-of-staff in 1918. He sat in the Dáil from 1921–23 as a member for the North-west division of Dublin, and after the treaty of 1922 became minister of defence for the Irish Free State. He succeeded Michael Collins, after the latter's death in 1922, as commander-in-chief of the Free State forces, and had the chief conduct of operations until the cease-fire order of 1923, in which year he was returned to the Dáil for Dublin city north. He resigned office in the spring of 1924 upon the executive requiring the resignation of three of his principal officers in connection with troubles arising out of demobilization and reorganizaton. In 1927 he resumed office as minister for local government.

MULE, a term sometimes applied, as equivalent to *hybrid*, to the produce of any two higher animals of different species, but in its ordinary acceptation employed to designate the offspring of the cross between the equine and asinine species. There are two kinds of mule—the *mule* proper, which is the hybrid produce of a male ass with a mare, and the *hinny*, the offspring of the stallion and female ass. The mule is the more valuable of the two, and the hinny, which is inferior in size, strength and beauty, is not deliberately bred.

In its short, thick head, long ears, thin limbs, small narrow hoofs, short mane, absence of "chestnuts" (horny growths) inside the hocks, and tail destitute of hair at the root, the mule resembles the ass, while in height and body, shape of neck and croup, uniformity of coat and in teeth it resembles the horse. It has the voice neither of the ass nor of the horse, but emits a feeble hoarse noise. The most common colour of the mule is a brown or bay-brown. It possesses the sobriety, patience, endurance and sure-footedness of the ass, and the vigour, strength and courage of the horse. As a beast of burden it is in many environments preferable to the horse, being less impatient under heavy weights, while the skin being harder and less sensitive renders it more capable of resisting sun and rain. The mule has been in use from early times; in modern times it has been largely employed for military transport.

Mules are wholly sterile both with other mules and with either parent species. Only one or two exceptions to this rule have been recorded, and even these are not usually regarded as authentic.

MÜLHAUSEN: *see* MULHOUSE.

MÜLHEIM-AM-RHEIN, a town in the Prussian Rhine province, on the right bank of the Rhine, 2 m. below Cologne, with which it was incorporated in 1914, and on the main lines of railway Cologne-Düsseldorf and Cologne-Elberfeld. Mülheim received municipal rights in 1322. Its industrial prosperity is in great part due to the influx of Protestants expelled from Cologne at the beginning of the 17th century. In 1784 the town suffered severely from an inundation caused by the rapid breaking-up of the ice on the Upper Rhine. There are important manufactures of silk, velvet, sailcloth, tobacco, vinegar, yarn and chemicals, in addition to rolling-mills, boiler works, telegraph works, breweries, tanneries and a shipbuilding yard.

MÜLHEIM-AN-DER-RUHR, a town in the Prussian Rhine province, on the Ruhr, an affluent of the Rhine, about 7 m. W.S.W. from Essen and at the intersection of several railways. Pop. (1925), 127,228. Mülheim was formerly included in the duchy of Berg, and became a town in 1508. In 1815 it passed to Prussia. It has a 12th century parish church. Its chief industry is iron-working and it has numerous blast-furnaces, rolling-mills, foundries and engine-works; it also manufactures leather, tobacco, paper and beer. Traffic is carried on in coal, and timber and colonial produce. In the neighbourhood are sandstone quarries, glassworks, and a carpet manufactory.

MULHOUSE (Mülhausen), a town of France, capital of an arrondissement in the department of Haut-Rhin, about 29 m. E.N.E. of Belfort, 56 m. S. of Strasbourg and 21 m. N.W. of Basle by rail. Pop. (1926) 96,019. It stands on the river Ill, here a part of the Rhone-Rhine canal system. Mulhouse was a free imperial city in the 14th century, and in 1648 was added to the Swiss confederation, with which it had been allied since 1466 and to which it belonged until 1798 when it joined France. From 1871 till 1918 it belonged to Germany. It is the great textile centre of Haut-Rhin and also manufactures machinery and chemicals. The *Hôtel-de-ville* (16th century) has curiously painted walls and a covered outside stairway. Here was made an interesting attempt at industrial town-planning, by Dollfus, in 1853.

MULL, the largest island of the Inner Hebrides, Argyllshire, Scotland. Pop. (1921) 3,389. It is bounded on the west and south by the Atlantic, on the north and north-east by the Sound of Mull, and on the east and south-east by the Firth of Lorne. Its greatest length is 27 m., and its greatest breadth 20 m. The coast is deeply indented, and there are several freshwater lakes. The principal mountains are Ben More (3,185 ft.), Ben Buy and Ben Creach. In the basaltic cliffs near Carsaig are numerous arches and caverns. Sheep and cattle are raised, and barley, oats and potatoes grown. Owing to the damp climate the island is better suited for grazing

than for cultivation. Granite is quarried. The fishing and shooting attract many sportsmen. There are several ancient castles, the principal being those of Duart and Aros. Close to the former is a lighthouse erected in memory of William Black, the novelist (d. 1898). About midway between Mull and Lismore is the Lady rock, visible at low water, on which, in 1523, Lachlan Maclean of Duart exposed his wife, a daughter of the second earl of Argyll, expecting that she would be drowned by the flowing tide. She was, however, saved by her clansfolk and her husband was afterwards slain by her brother. Tobermory ("the Well of Mary," so called from a spring of local celebrity), which rises from a picturesque bay, is the only town (pop. 850). Founded in 1788 as a station for fishing-boats, it has a harbour and considerable local trade. It is also a summer resort, with communication by steamer with Oban and Glasgow. Off the north-western shore of Mull, separated by a narrow strait, lie the inhabited islands of Ulva, $4\frac{3}{4}$ m. long and $2\frac{1}{2}$ m. broad, and Gometra. Little Colonsay lies about 2 m. south of Ulva. Farther west is the small group of the Treshnish Isles.

MULLAH, in Mohammedan countries a learned man, a teacher, a doctor of the law. (Arabic *maula,* a term which originally expresses the legal bond connecting a former owner with his manumitted slave.) In India the term is applied to the man who reads the Qu'ran and also to a Muslim schoolmaster. In countries like Afghanistan the mullahs exert an influence over the populace which sometimes rivals that of the amir himself.

In the Indian frontier risings of 1897–98 the "mad mullah" of Swat led the attack upon the Malakand, while the Hadda mullah was largely responsible for the risings amongst the Mohmands, Afridis, and Orakzais. The leader of the risings in Somaliland in 1899–1910 was similarly known as the "mad mullah."

MULLEIN (*Verbascum Thapsus*), a densely woolly, biennial herb of the figwort family (Scrophulariaceae), native to Europe and Asia, common in the British Isles and extensively naturalized in North America. It grows erect, 2 to 7 ft. high, with stout unbranched stems, conspicuously winged by the decurrent bases of the large, thick, oblong, slightly-toothed, pointed leaves, sometimes a foot long. The bright yellow flowers, about an inch broad, appearing from June to September, are closely crowded in a long, dense spike. In some districts the mullein is a troublesome weed.

BY COURTESY OF THE WILD FLOWER PRESERVATION SOCIETY

THE GREAT MULLEIN (VERBASCUM THAPSUS), FOUND IN EUROPE, ASIA AND NORTH AMERICA

MÜLLER, FERDINAND VON, Baron (1825–1896), German botanist and explorer, was born at Rostock on June 30, 1825, and was educated in Schleswig. In 1847 he emigrated to South Australia and five years later, was appointed government botanist for Victoria. As phytographic naturalist, he joined the expedition sent out under Augustus Gregory by the duke of Newcastle, secretary of state for the colonies. From 1857 to 1873 he was director of the Botanical Gardens, Melbourne, and not only introduced many plants into Victoria, but made the excellent qualities of the blue gum tree (*Eucalyptus globulus*) known all over the world, and succeeded in introducing it into the south of Europe, North and South Africa, California and the extra-tropical portions of South America. For these services he was decorated by many foreign countries, and was created baron of the kingdom of Württemberg in 1871. He died at Melbourne on Oct. 9, 1896.

His publications include *Fragmenta phytographica Australiae* (11 vols., 1862–81); *Plants of Victoria* (2 vols., 1860–65) and works on the Eucalyptus, Myoporeceae, Acacias and Salsolaceae.

MÜLLER, FRIEDRICH (1749–1825), German poet, dramatist and painter, usually known as Maler (*i.e.,* painter). Müller, was born at Kreuznach on Jan. 13, 1749, and became (1777) court painter at Mannheim. Next year he left for Italy, where the rest of his life was spent. He died in Rome on April 23, 1825. Müller abandoned painting soon after his arrival in Italy. His principal works are *Fausts Leben dramatisiert* (1778); *Golo und Genoveva* (begun in 1776, but not published till 1811); and the idylls, *Die Schafschur* (1775) and *Das Nusskernen* (1811).

See the selection, *Ausgewählte Dichtungen* (ed. H. Hettner 2 vols. 1868); monographs by Seuffert (1877), Luntowski (1908) and *Bibliographie* by Fr. Meyer (1912).

MÜLLER, GEORGE (1805–1898), English preacher and philanthropist, was born near Halberstadt, Germany, on Sept. 27, 1805, the son of an exciseman. In 1830 he became minister of a small congregation at Teignmouth, Devonshire. He contended that the temporal as well as the spiritual needs of life could be supplied by prayer, and on this principle abolished pew rents and refused to take a fixed salary. After two years at Teignmouth, Müller removed to Bristol, where he spent the rest of his life. He devoted himself particularly to the care of orphan children. He began by taking a few under his charge, but in course of time their number increased to 2,000, settled in five large houses erected for the purpose at Ashley Down, near Bristol. The money required for the carrying on of this work was voluntarily contributed, mainly as a result of the wide circulation of Müller's narrative *The Lord's Dealings with George Müller.* When he was over 70 he started on a preaching mission, which lasted nearly 17 years and included Europe, America, India, Australia and China. He died at Bristol on March 10, 1898.

See A. T. Pierson, *George Müller of Bristol* (1899).

MÜLLER, HERMANN (1876–), German politician, was born May 18, 1876 at Mannheim. From 1899 to 1906 he was editor of the Socialist newspaper the *Görlitzer Volkszeitung,* and from 1906 onwards was a member of the directing board of the German Social Democratic party. From 1916 to 1918 he was a member of the *Reichstag.* On Aug. 1, 1914, he went to Paris with the object of finding out whether international action by the Socialists of France and Germany could be initiated in order to avert the World War. His mission was unsuccessful, and he had great difficulty in making his way back to Germany through the French lines. His report did much to determine the attitude of the German Social Democrats in voting in the *Reichstag* for the first war credit. On June 21, 1919, he was appointed Minister for Foreign Affairs—under the chancellorship of Gustav Bauer—and in this capacity went to Versailles and with the Colonial Minister, Dr. Bell, signed the Peace Treaty for Germany on June 28, 1919. After the resignation of the Bauer Ministry, which followed upon the Kapp Putsch (March 1920), Müller was appointed Chancellor of the *Reich,* an office which he held till the following June, when the result of the general elections for the *Reichstag* necessitated the formation of a Coalition Ministry with Fehrenbach of the Catholic Centre party as Chancellor. Thereafter Müller continued to play a leading part in the affairs of the Social-Democratic party, whose chairman in the *Reichstag* he was. After the general election of May 1928, which brought a general swing to the Left, he was asked by the President to form the new Government. After wearisome negotiations with the different parties concerned, he succeeded in forming a "Cabinet of Personalities," based on the idea of the Great Coalition including all parties from the Social Democrats to the German People's party; he himself was Chancellor.

MÜLLER, JOHANNES PETER (1801–1858), German physiologist and comparative anatomist, was born in Coblenz on July 14, 1801. He studied at Bonn university, where he taught from 1824 until 1833, when he received the chair of anatomy and physiology at Berlin. He died on April 28, 1858. The appearance of his *Handbuch der Physiologie des Menschen,* 1833–40 (Eng. trans., Dr. William Baly, London, 1842) marked the beginning of a new period in the study of physiology, by showing its dependence on the other sciences. The most important part of the

work deals with the physiology of the nerves and the senses. Here Müller first declared that the kind of sensation following stimulation of a sensory nerve depends not on the mode of stimulation, but upon the nature of the sense-organ which transmits it to other nerve-terminals, and expounded the mechanism of voice, speech and hearing. Müller is also noted for his early investigations of specific nerve energies, his discoveries of the foetal Müllerian duct (1825) and of the lymph-hearts in the frog (1832), his work on tumours (1838) and his description of the parasitic disease, psorospermosis (1841). In the later part of his life he devoted himself to the study of ocean fauna and comparative anatomy.

In addition to his *Handbuch der Physiologie,* Müller published *Zur vergleichenden Physiologie des Gesichtssinns* (1826); *Ueber die phantastischen Gesichtserscheinungen* (1826); *Bildungsgeschichte der Genitalien* (1830); *De glandularum secernentium structura* (1830); *Vergleichende Anatomie der Myxinoiden* (1834–43); *Systematische Beschreibung der Plagiostomen* (1841) with F. G. J. Henle; *System der Asteriden* (1842) and *Horae ichthyologicae* (1845–49) with F. H. Troschel.

MÜLLER, JOHANNES VON (1752–1809), Swiss historian, was born on Jan. 3, 1752, at Neunkirch, near Schaffhausen, where his father was pastor. From 1774 to 1780 he lived at Geneva where he produced his *Allgemeine Geschichte,* a brilliant study of universal history (not published till 1810). In 1780 he completed the first volume of his *Geschichten der Schweizer,* bearing the imprint of Boston, U.S.A., on account of difficulties with the Swiss censor. His *Reisen der Päpste* appeared in 1782.

In 1786 he became librarian to the elector-archbishop of Mainz, who obtained his elevation to nobility from the emperor in 1791. In June 1786 he issued vol. i. (reaching to 1412) and two years later vol. ii. (to 1436) of the definitive form of his Swiss history.

After the capture of Mainz by the French (1792), he entered the service of the emperor Leopold as an imperial aulic councillor. At Vienna he became chief librarian of the imperial library in 1800, and in 1795 he issued vol. iii. (to 1443) of his Swiss history. In 1804 he became historiographer, war councillor and member of the Academy at Berlin. In 1805 vol. iv. (to 1475) appeared. But in 1806 he became strongly inclined towards Napoleon, from whom he accepted (end of 1807) the office of secretary of State for the kingdom of Westphalia. At the end of 1808 he published vol. v. (to 1489) of his great work. He died at Cassel on May 29, 1809. His *Swiss History,* based largely on the chronicles of Tschudi (*q.v.*), now possesses a literary value only, but it remarkably stimulated Swiss patriotism.

Müller's *Werke* were published at Tübingen, in 27 vols. (1810–19), and re-issued, in 40 vols., at Stuttgart (1831–35). The *Swiss History* was re-issued at Leipzig and Zürich, in 15 vols. (1824–53), with continuations by other hands. A French translation of the German edition appeared, in 18 vols., at Paris and Geneva (1837–51). His *Universal History* was translated into English by J. C. Prichard (1818).

See A. H. L. Heeren, *J. von Müller der Historiker* (1809); J. M. H. Döring, *Leben* (1835); C. Monnard, *Biographie* (1839); H. W. J. Thiersch, *Über J. von Müller und seinen handschriftlichen Nachlass* (1881); C. Henking, *J. von Müller* (1909 and 1928). F. Schwarz's pamphlet *J. von Müller und seine Schweizergeschichte* (Bâle, 1884) traces the genesis of the *History*. *See* also: *J. Müller's Briefe,* edit. J. H. Füsslin (Zürich, 1812); and those to Ch. Bonnet, etc. (Stuttgart, 1835); *Briefe,* edit. Maurer-Constant, 6 vols. (Schaffhausen 1839–40); *Der Briefwechsel der Brüder J. G. Müller und J. von Müller,* 2 vols. (1893).

MÜLLER, KARL OTFRIED (1797–1840), German scholar, was born at Brieg in Silesia on Aug. 28, 1797. He was educated partly in Breslau, partly in Berlin, and his first book, *Aegineticorum liber,* was published in 1817. In 1819 he became professor of ancient literature at Göttingen, but in 1839 political disturbances led him to travel. After investigating Athens and other places, he started excavations at Delphi. He died of intermittent fever at Athens on Aug. 1, 1840. His aim was to form a conception of Greek life as a whole, and his work marks an epoch in Hellenic study.

Among his historical works the foremost place belongs to his *Geschichte hellenischer Stämme und Städte: Orchomenos und die Minyer* (1820), and *Die Dorier* (1824; Eng. trans. by H. Tufnell and Cornewall Lewis, 1830). He introduced a new standard of accuracy in the cartography of ancient Greece. In 1828 he published *Die Etrusker,* a treatise on Etruscan antiquities. His *Prolegomena zu einer wissenschaftlichen Mythologie* (1825; Eng. trans., J. Leitch, 1844) prepared the way for the scientific investigation of myths; while the study of ancient art was promoted by his *Handbuch der Archäologie der Kunst* (1830; Eng. trans., J. Leitch, 1847), and *Denkmäler der alten Kunst* (1832), which he wrote in association with C. Osterley. In 1840 appeared in England his *History of the Literature of Ancient Greece* (published in Germany, 1841).

See memoir of his life by his brother Eduard, prefixed to the posthumous edition of K. O. Müller's *Kleine deutsche Schriften* (1847). A biography composed from his letters was published by O and E. Kern, *K. O. Müller, Lebensbild in Briefen an seine Eltern* (1908).

MÜLLER, LUCIAN (1836–1898), German scholar, was born at Merseburg in Prussian Saxony on March 17, 1836, and died at St. Petersburg (Leningrad), where he was professor of Latin, on April 24, 1898. He lived for five years in Holland, and wrote *Geschichte der klassischen Philologie in den Niederlanden* (1869). His *De re metrica poetarum latinorum* (1861) marks an epoch in the study of Roman metre.

MÜLLER, MAX [Friedrich Maximilian] (1823–1900), Anglo-German Orientalist and comparative philologist, was born at Dessau on the 6th of December 1823, being the son of Wilhelm Müller (1794–1827), the German poet, celebrated for his phil-Hellenic lyrics, who was ducal librarian at Dessau. Mendelssohn, who was Max Müller's godfather, dissuaded him from indulging his natural bent to the study of music; Professor Brockhaus of the University of Leipzig, where Max Müller matriculated in 1841, induced him to take up Sanskrit; Bopp, at Berlin (1844), made the Sanskrit student a scientific comparative philologist; Schelling at the same university, inspired him with a love for metaphysical speculation, though failing to attract him to his own philosophy; Burnouf, at Paris in the following year, by teaching him Zend, started him on the track of inquiry into the science of comparative religion, and impelled him to edit the *Rig Veda;* and when, in 1846, Max Müller came to England upon this errand, Bunsen, in conjunction with Professor H. H. Wilson, prevailed upon the East India Company to undertake the expense of publication. Bunsen gave him introductions to Queen Victoria and the prince consort, and to Oxford university. In 1848 the printing of his *Rig Veda* at the University Press obliged him to settle in Oxford. Max Müller was appointed deputy Taylorian professor of modern languages in 1850, and became an honorary fellow of Christ Church and a fellow of All Souls. He published during this period the essays subsequently collected as *Chips from a German Workshop,* and his *History of Ancient Sanskrit Literature* (1859).

When at last the chair of Sanskrit fell vacant in 1860, Max Müller failed to secure election on account of his foreign birth and his liberal connections, and the choice fell on Monier-Williams. It was the one great disappointment of Max Müller's life, and made a lasting impression upon him. Directly, Sanskrit philology received little more from him, except in connection with his later undertaking of *The Sacred Books of the East;* but indirectly, by emphasizing its importance, as he did in his *Science of Language,* two courses of lectures delivered at the Royal Institution in 1861 and 1863, he rendered great service. Prichard had proved the Aryan affinities of the Celtic languages by the methods of comparative philology so long before as 1831; Winning's *Manual of Comparative Philology* had been published in 1838; the discoveries of Bopp and Pott and Pictet had been recognized in brilliant articles in the *Quarterly Review,* and had guided the researches of Rawlinson. Max Müller popularized the subject. He was on less sure ground in another department of the study of language—the problem of its origin. He wrote upon it as a disciple of Kant, whose *Critique of Pure Reason* he translated. His essays on mythology are among the most delightful of his writings, but their value is somewhat impaired by a too uncompromising adherence to the seductive generalization of the solar myth.

Max Müller's studies in mythology led him to the comparative

science of religions. His *Introduction to the Science of Religion* (1873: the same year in which he lectured on the subject, at Dean Stanley's invitation, in Westminster Abbey, this being the only occasion on which a layman had given an address there) marks an epoch. It was followed by the four volumes of Gifford lectures, delivered between 1888 and 1892; but the most tangible result of the impulse he had given was the publication under his editorship, from 1875 onwards, of *The Sacred Books of the East,* in fifty-one volumes, including indexes, all but three of which appeared under his superintendence during his lifetime. These comprise translations by the most competent scholars of all the really important non-Christian scriptures of Oriental nations. Max Müller also wrote on Indian philosophy in his later years, and he stimulated the search for Oriental manuscripts and inscriptions which resulted in discoveries of early Buddhist scriptures, in their Indian form, made in Japan. He was on friendly terms with Japanese scholars, and after his death his library was purchased by the University of Tōkyō.

In 1868 Max Müller had been indemnified for his disappointment over the Sanskrit professorship by the establishment of a chair of comparative philology to be filled by him. He ceased to lecture in 1875, when entering upon the editorship of *The Sacred Books of the East.* He was a curator of the Bodleian Library, and a delegate of the University Press. His hospitality was ample, especially to visitors from India, where he was far better known than any other European Orientalist. His distinctions, conferred by foreign governments and learned societies, were innumerable. He became a naturalized Englishman, was in high favour at court, and was sworn of the privy council. He died at Oxford on Oct. 28, 1900.

Max Müller's *Collected Works* were published in 1903.

(R. G.; X.)

MÜLLER, WILHELM (1794–1827), German lyric poet, was born at Dessau on Oct. 7, 1794, and died there on Sept. 30, 1827. His reputation was made by the *Gedichte aus den hinterlassenen Papieren eines reisenden Waldhornisten* (2 vols., 1821–1824), and the *Lieder der Griechen* (1821–1824), a collection inspired by the Greek war of independence. Two volumes of *Neugriechische Volkslieder,* and *Lyrische Reisen und epigrammatische Spaziergänge,* followed in 1825 and 1827. Müller also translated Marlowe's *Faustus,* and edited a *Bibliothek der Dichtungen des 17. Jahrhunderts* (1822–1827; 10 vols.). Schubert set many of his lyrics to music, among others "Die Schöne Müllerin" and "Winterreise."

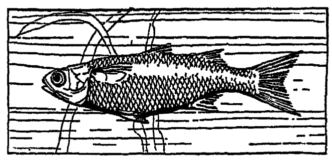
Wilhelm Müller's *Gedichte* were first collected in 1837 (4th ed., 1858); edited by his son, F. Max Müller (1868); there are also numerous more recent editions, notably one in Reclam's *Universalbibliothek* (1894); critical edition by J. T. Hatfield (1906). Müller's *Vermischte Schriften* were edited with a biography by G. Schwab (3 vols., 1830).

MÜLLER, WILLIAM JAMES (1812–1845), English landscape and figure painter, was born at Bristol on June 28, 1812, his father, a Prussian, being curator of the museum. He studied painting under J. B. Pyne. His early subjects deal mainly with the scenery of Gloucestershire and Wales. In 1833 he figured for the first time in the Royal Academy with his "Destruction of Old London Bridge—Morning," and next year he made a tour through France, Switzerland and Italy. Four years later he visited Athens, extending his travels to Egypt, and in the sketches executed during this period and the paintings produced from them his power and individuality are apparent. After his return he settled in London, where he exhibited regularly. In 1840 he again visited France, where he executed a series of sketches of Renaissance architecture, twenty-five of which were lithographed and published in 1841, in a folio entitled *The Age of Francis I. of France.* In 1843 he accompanied Mr. (afterwards Sir) Charles Fellows to Lycia, where he made a number of masterly sketches. He died at Bristol on Sept. 8, 1845. The print room of the British Museum and the Tate Gallery possess rich collections of Müller's works.

A biography by N. Neal Solly was published in 1875.

MULLET, the name of two different kinds of fishes, distinguished as red mullets and grey mullets.

Red mullets (genus *Mullus*) are marine fishes, with two short dorsal fins, the first composed of feeble spines, the second of branched rays. The body is covered with large thin scales. The anterior profile of the head slopes downwards to the small mouth, which has small, feeble teeth. There are two sensitive barbels on the lower jaw, generally laid back in a groove, but capable of erection when needed. About 40 species are known, chiefly from the tropical and subtropical parts of the Indo-Pacific ocean. In European waters two species occur (*Mullus surmuletus* and *M. barbatus*). The former, in addition to the general red colour,



BY COURTESY OF THE NEW YORK ZOOLOGICAL SOCIETY

THE COMMON MULLET

has three to five bright yellow bands along the sides from head to tail; these are absent in the other form. The striped form is usually found on the coasts of England, while in the Mediterranean both kinds occur.

The largest red mullets weigh only two or three pounds. They are ground-feeders, using their barbels in discovering their food, which consists of crustacea, worms, and, in the larger species, of small fishes. Their brilliant colours are simple and evanescent; in many, red prevails. All the species are esteemed as food, but none equals the European species. During winter the fish retire into deep water, late in spring and during summer they approach the coasts and enter even brackish water, but they do not come towards the shore to breed. At Naples they spawn from May to August; their ova are buoyant and transparent.

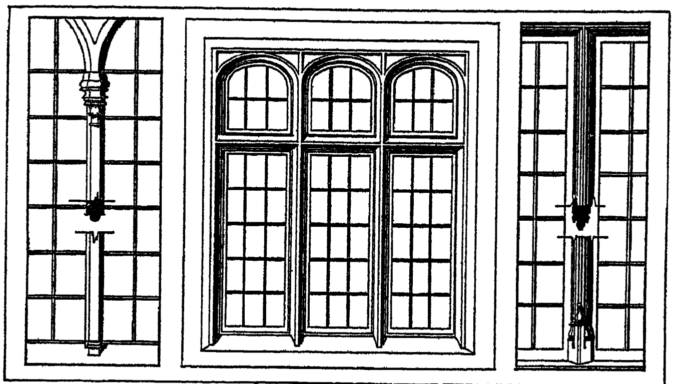
The grey mullets form a very distinct family, *Mugilidae.* They enter brackish water, live always close to the shore, and some of the tropical forms inhabit the fresh water without, however, penetrating far inland. Their body is elegantly formed, wedge-shaped, and covered with scales of moderate size. The anterior of the two short dorsal fins is composed of four stiff spines. The caudal fin is strong and bilobed. The mouth is narrow, transverse in the true *Mugil,* and without, or with but feeble, teeth. About 70 different species are known, from most parts of the temperate and tropical zones; they swim in small schools and are abundant wherever they occur. The commonest British species is *Mugil cephalus;* found also on both coasts of North America and elsewhere. Some of the fresh-water grey mullets of the tropics have been formed into a separate genus, *Agonostoma.*

Grey mullets may grow to a weight of 10 or 12 pounds. Those in which distinct teeth are developed feed on small aquatic animals, while the diet of those without teeth consists of animalcules, confervae, or minute organic débris mixed with the mud and sand, which they swallow in large quantities. To prevent the gills from being clogged by sand or mud, each branchial arch is provided with a series of closely set gill-rakers, each series fitting into the series of the adjoining arch; they constitute a sieve permitting the passage of the water, while retaining other substances. Grey mullets are plainly coloured, generally greenish on the upper parts and more or less silvery on the side. They are wholesome food. Grey mullets are cultivated in fish farms in Italy.

MULLINGAR, county town of co. Westmeath, Ireland, near the River Brosna and on the Royal canal, 50 m. W. by N. of Dublin. Pop. (1926) 5,293. It is a junction on the Great Southern railway. Here is the Roman Catholic cathedral for the diocese of Meath. Tanning, brewing and the manufacture of coarse woollens are carried on, and the town is an agricultural centre. Mullingar was one of the ancient palatinate towns. It possessed an Augustine convent (1227) and a Dominican convent (1239), but both were dissolved by Elizabeth. The town was the headquarters of William III. before the siege of Athlone. It is a centre for trout-fishing in Loughs Ennell and Owel.

MULLION, in architecture, a slender, vertical division between adjacent lights or sub-divisions in a window, or between adjacent windows in a group. Mullions appear with the invention of tracery (*q.v.*), and are particularly characteristic of Gothic architecture throughout, and early Renaissance in north and west Europe. In traceried windows, mullions are frequently chamfered or bevelled on the edges, and sometimes decorated, in addition, with a colonnette; but in late Gothic work, more

elaborate mouldings are common. In the rectangular window groups common in late Gothic and early Renaissance secular work, the face of the mullion is usually set back from the face of the wall so that one moulding or series of mouldings runs unbroken round the entire group. The mullion itself is usually moulded or chamfered and this moulding or chamfer is continued around the top and sides of each light. In windows whose



MULLION. LEFT AND RIGHT, LATE FRENCH GOTHIC; CENTRE, ENGLISH TUDOR

tracery sub-divides the whole into more than three lights, mullions may be of different sections, with certain mullions increased in size, or may carry an additional moulding. The entire group is systematized into sub-divisions of two or three lights each, the larger mullions enclosing each sub-division.

MULLITE (named from the island of Mull, where it was first recognized as a rock mineral), a mineral of the composition $3Al_2O_3{\cdot}2SiO_2$ crystallizing in the rhombic system. The mineral shows an extraordinary similarity in its physical properties to sillimanite (*q.v.*) as is indicated by the following data:

	Mullite	Sillimanite
Prism angle 110, 110	89° 13′	88° 15′
Cleavage	010	010
Refractive indices	α 1·642 γ 1·654	α 1·657 γ 1·677
Optic axial angle	45°–50°	25°–30°

The refractive indices of artificial mullite rise with a content of Fe_2O_3 and TiO_2; with 0·86% Fe_2O_3+1·12% TiO_2 the values become α=1·651, γ=1·668 thus approaching those of natural sillimanite. Such iron- and titanium-containing mullites are pleochroic in pink and violet tints. Laboratory investigations show that mullite is the only compound of alumina and silica stable at high temperatures. Mullite itself melts incongruently at 1810° C with separation of corundum while sillimanite is essentially different in its thermal behaviour, dissociating at 1545° C (the eutectic temperature of mullite and cristobalite) into mullite and a silica-rich liquid. The two other compounds of alumina and silica, viz. andalusite and kyanite, similarly break up into mullite and silica on heating, but at lower temperatures, decomposition beginning in andalusite at about 1400° C and in kyanite between 1100° C and 1200° C. Natural mullite has so far been recognized only in buchites or fused argillaceous enclosures in intrusive igneous rocks. In the island of Mull, it occurs together with cordierite, corundum, spinel and anorthite, forming xenoliths in Tertiary tholeiite intrusions. In normal contact aureoles the place of mullite is taken by andalusite and sillimanite. Its presence in any assemblage may be taken as evidence of exceptionally high temperatures. Between mullite and sillimanite there is no evidence of any transition in composition, no solid solutions being recognized in laboratory experiments. It may be mentioned that mullite is regarded by W. Eitel and his co-workers as $2Al_2SiO_5+Al_2O_3$, that is, extremely fine or disperse corundum in fibrous sillimanite, but these conclusions are unconfirmed. Examined in fine powder by X-ray methods mullite and sillimanite give identical spectra.

Mullite is an important constituent of ceramic wares and forms practically the sole constituent of Marquardt porcelain. The mullite of these wares was previously regarded as sillimanite. The importance of the recognition of the compound $3Al_2O_3{\cdot}2SiO_2$ is clear when the refractory character of various $Al_2O_3-SiO_2$ mixtures is considered. Mixtures of the composition $3Al_2O_3{\cdot}2SiO_2$ and those still richer in alumina begin to melt only at 1810° C, whereas the slightest excess of silica over the $3Al_2O_3{\cdot}2SiO_2$ ratio suffices to cause an initial melting at 1545° C, the eutectic temperature. (C. E. T.)

MULOCK, SIR WILLIAM (1843–), Canadian statesman and jurist, was born at Bond Head, Ontario, on Jan. 19, 1843, the son of T. H. Mulock, M.D. From 1882 to 1905 he was a prominent member of the Liberal party in the Federal house; postmaster-general from 1896 to 1905, and minister of labour from 1900 to 1905. He introduced many improvements into the Canadian postal service, and in 1898 in face of much opposition induced the Inter-Imperial Postal Conference to adopt the principle of penny postage within the British Empire. In 1905 he resigned office, and was appointed chief justice of the exchequer division of the High Court of the province of Ontario (1905–23). In 1923 he was made chief justice of Ontario. From 1881 to 1900 he was vice-chancellor of the university of Toronto, and chancellor since 1924, and was largely responsible for the federation between that body and the Victoria university (Methodist).

MULREADY, WILLIAM (1786–1863), Irish subject painter, was born at Ennis, Co. Clare, on April 30, 1786. When he was about five years old his father, a leather-breeches maker by trade, removed to London. In 1800 he was admitted a student of the Academy, and two years later he gained the silver palette of the Society of Arts. He was associated with John Varley, the eccentric water-colour painter and drawing-master, whom he assisted in the tuition of his pupils, who included Cox, Fielding, Linnell, William Hunt, and Turner of Oxford. At 18 he married a sister of Varley's, and at 24 he was the father of four sons. The marriage was unhappy, and the pair separated before many years. He "tried his hand at everything," as he said, "from a miniature to a panorama." He painted portraits, taught drawing, and up till 1809 designed illustrations to a series of children's penny books.

Mulready had a special aptitude for genre-painting, and in 1809 produced the "Carpenter's Shop," and in 1811 the "Barber's Shop," pictures influenced by the example of Wilkie and the Dutch painters. In 1813 he exhibited his "Punch," a more original and spontaneous work, and two years later his "Idle Boys" procured his election as A.R.A. Next year he became R.A., and showed his "Fight Interrupted." It was followed by the "Wolf and the Lamb" (1820), the "Convalescent" (1822), "Interior of an English Cottage" (1828), "Dogs of Two Minds" (1830), the "Seven Ages" (1838), and in 1839 and 1840 by the "Sonnet and First Love," two of the most perfect and poetical of the artist's works. In 1840 he designed an allegorically covered postal envelope (the "Mulready envelope," soon discontinued) for Rowland Hill, and a set of illustrations to *The Vicar of Wakefield*, which were succeeded by his paintings of the "Whistonian Controversy" (1844), "Choosing the Wedding Gown" (1846), and "Sophia and Burchell Haymaking" (1849). He died on July 7, 1863.

MULTAN or **MOOLTAN**, a city, district and division of British India, in the Punjab. The city is 4 m. from the left bank of the Chenab, near the ancient confluence of the Ravi with that river. Pop. (1921), 84,806. The city is enclosed on three sides by a wall, but large and irregular suburbs have grown up outside the wall. The principal buildings in the Fort include the shrines of two Mohammedan saints and an ancient Hindu temple. The cantonments form the headquarters of a brigade. Multan has manufactures of carpets, silk and cotton goods, shoes, glazed pottery and enamel work, and an annual horse fair. It is moreover one of the most important trade-centres in the Punjab.

The District of Multan occupies the lower angle of the Bari Doab, or tract between the Sutlej and the Chenab, with an extension across the Ravi. Area, 5,939 sq.m. The population in 1921 was 890,264. The principal crops are wheat, millets, pulse, oil-seeds, cotton and indigo. There are factories for ginning and pressing cotton. Indigo is made only by native processes. Irriga-

tion was till recently conducted only by inundation channels from the boundary rivers, but there is now a large area irrigated from the lower Bari Doab permanent canal. The heat of Multan is notorious.

The early Arab geographers mention Multan as forming part of the kingdom of Sind, which was conquered for the caliphate by Mohammed bin Kasim in the middle of the 8th century. On the dismemberment of the Mogul Empire in the middle of the 18th century, Multan fell to the Afghans, who held it with difficulty against the Sikhs. At length, in 1818, Ranjit Singh, after a long siege carried the capital by storm; and in 1821 he made over the administration of Multan with five neighbouring districts to Sawan Mal, who raised the province to a state of prosperity by excavating canals and inducing new inhabitants to settle. After the establishment of the council of regency of Lahore, difficulties arose between Mulraj, son and successor of Sawan Mal, and the British officials, which led to his rebellion, and culminated in the second Sikh war and the annexation of the whole of the Punjab. The city of Multan, after a stubborn defence, was captured in January 1849. The district at once passed under direct British rule, and order was not disturbed even during the Mutiny.

MULTIGRAPH: *see* Office Appliances.

MULTIPLEPOINDING, in Scots law, the technical term for a form of action by which conflicting claims to the same fund or property are determined. The action is brought either by the holder of the fund as pursuer and real raiser on the allegation that he is called on to make double payment, or by a claimant on the fund who brings the action in the name of the holder as pursuer and nominal raiser, calling himself a defender and real raiser. All who have any claims in the fund or property in question are ordered to appear and give in their claims; the court then prefers them according to their respective rights, and the holder of the fund or property in dispute on payment or delivery is absolved from any further claim in regard to it. It corresponds to the process of *inter-pleader* in English law.

MULTIPLE SHOPS: *see* Chain Stores.

MULTITUBERCULATA, an order of extinct mammals. Their relationships to other groups are best considered by giving a brief outline of the Mesozoic mammals.

Although the Cenozoic Era is popularly known as the age of mammals, about two-thirds of mammalian evolution took place during the Mesozoic. The remains of Mesozoic mammals are among the rarest, most fragmentary and most valuable of all fossils. These earliest mammals were very small, averaging about the size of a rat. It is clear that they were locally abundant and included insectivorous, carnivorous and herbivorous types.

The oldest known mammals are from the late Triassic (or possibly earliest Jurassic) of England, Germany and South Africa. These belong to two quite distinct groups both referred to the Allotheria (*see* below). Both are very aberrant, however, and the true ancestral Triassic types of mammals are still unknown.

The Jurassic mammals are much better known, and are divided into four orders, all extinct. Characteristic of the whole Mesozoic and also of the oldest Cenozoic (Paleocene) were the Allotheria or Multituberculata, ranging from the upper Triassic into the true Eocene and known to have occurred in Europe, Africa, Asia and North America. They had a single pair of enlarged incisors below and two or three pairs, of which only one was enlarged, above. The cusps of the molars were arranged in two or three straight longitudinal rows. In the Jurassic each molar had only five or six cusps, but in some of the later types as many as 30 cusps occurred on a single tooth—whence the name. The upper premolars were generally composed of conical cusps, less regularly arranged than those of the molars, and, except in a few aberrant forms, the lower premolars were developed into large, compressed, sharp-edged shearing teeth. They appear to have been vegetarians. Some show a superficial resemblance to the living rat-kangaroos of Australia, but recent work indicates that the multituberculates constituted an entirely separate subclass, not ancestral to any later mammals and related to the latter only through common ancestry in the Triassic or even earlier.

In the second Jurassic order, the Triconodonta, the molar teeth have three cusps each, arranged in a straight longitudinal line. Although small, these mammals were predaceous carnivores. They were confined to the Jurassic and probably represent another aberrant offshoot of the earliest mammalian stock.

A third Jurassic order, the Symmetrodonta, includes mammals long classed with the Triconodonta, although recent work indicates they are a distinct order related rather to the Pantotheria than to the Triconodonta. Confined to the upper Jurassic, so far as known, they are characterized by triangular teeth, typically with three cusps.

The last order of Jurassic mammals, the Pantotheria, was the most important phylogenetically. The dentition, while more primitive and different in details, has a broad resemblance to that of the most generalized insectivores and marsupials. The typical dental formula was $I\frac{4}{4}$; $C\frac{1}{1}$; $P\frac{4}{4}$; $M\frac{7}{8}$, although various genera show marked modifications from this, chiefly by reduction. The upper molars were triangular with a large internal cusp and usually one main external cusp and several lesser ones. The lower molars typically had four main cusps arranged in an asymmetrical triangle, followed by a heel, or talonid, with one cusp. The pantotheres apparently represent the stock which gave rise early in the Cretaceous to the marsupials and placentals. The earliest and most primitive pantothere was *Amphitherium* from the English middle Jurassic (Stonesfield).

Lower Cretaceous mammals are known only from a few poorly preserved teeth from the English Wealden, of slight importance, but the upper Cretaceous mammals are relatively well known. The multituberculates continue as more advanced forms referred to the family Ptilodontidae, with more numerous molar cusps. The other Jurassic forms, however, have disappeared and are replaced by the earliest members of the Insectivora and Marsupialia (*qq.v.*).

The Cretaceous marsupials, known at present only from North (and possibly South) America, are all closely related to the living opossums, but are much more varied in size and other characters. They probably represent a widespread complex of primitive marsupials from which the later and more specialized South American and Australian forms were derived.

Of the upper Cretaceous Insectivora, only a single genus, *Gypsonictops,* is known with certainty from North America, but in Asia the expeditions of the American Museum of Natural History have brought to light eight skulls. These are very close to the ancestral stock from which the majority of placental mammals were derived. *Zalambdalestes,* a peculiar long-snouted form, and *Deltatheridium,* a very primitive and generalized type, are the most important.

The following is an outline classification of the major groups of the Mammalia:

Class Mammalia
- *Subclass Allotheria*
  - Order Multituberculata
- *Subclass Prototheria*
  - Order Monotremata (*q.v.*)
- *Subclass Theria*
  - Infraclass Pantotheria
    - Order Symmetrodonta
    - Order Pantotheria, *sensu stricto*
  - Infraclass Metatheria
    - Order Marsupialia (*q.v.*)
  - Infraclass Eutheria
  - *Incertae sedis:* Order Triconodonta.

See Mammalia, Palaeontology; also G. G. Simpson, *Catalogue of the Mesozoic Mammalia in the Geological Department of the British Museum* (1928). (G. G. Si.)

MUMMERS, bands of men and women in mediaeval and later England and elsewhere, who, during periods of public festivity, particularly at Christmas, dressed in fantastic clothes and wearing masks or disguised as animals, serenaded the people outside their houses or joined in the revels within. The term is also applied to the actors in the old English rural folk-plays of St. George, etc.; and "mumming" thus becomes a contemptuous synonym for any form of stage-playing.

The verb "to mum" means both to mutter and to be silent, and "mummer" apparently comes from one or both of these

senses. Mumming seems to have been a survival of the Roman custom of masquerading during the annual orgies of the Saturnalia. Mumming led to such outrages in England in the 16th century that Henry VIII. issued a proclamation declaring the wearing of a mask or disguise a misdemeanour. Stow gives an account of an elaborate mummery held in 1377 by the London citizens to amuse the son of the Black Prince, then living at Kennington (*Survey*, 1603, p. 97). In Scotland, where mumming long survived at Christmas, Hogmanay, New Year's Day and Handsel Monday, mummers were called "guisards." They usually presented on these four nights a crude drama called *Galatian*, which, in various versions, was common throughout the Lowlands of Scotland (*see* Chambers's *Popular Rhymes*, p. 170).

MUMMIUS, LUCIUS (2nd century B.C.), surnamed Achaïcus, Roman statesman and general. Consul in 146 B.C. Mummius was appointed to take command of the Achaean War. On capturing Corinth he massacred the inhabitants, removed all the works of art to Rome and destroyed the city. This is explained by Mommsen as due to the interference of the commercial party in the Senate. In 142 he was censor with the younger Scipio Africanus. Mummius was the first *novus homo* of plebeian origin who received a distinctive cognomen for military services. His indifference to works of art and ignorance of their value is shown by his well-known remark to those who contracted for the shipment of the treasures of Corinth to Rome, that "if they lost or damaged them, they would have to replace them."

MUMMY, a dead body preserved by the ancient Egyptian or other method of embalming (Persian *mumiai*, wax; later meaning pitch or asphalt).

Origin of Mummification.—In Egypt, in prehistoric times, the dead were buried, sometimes loosely wrapped in mats or skins, in shallow graves, the body being placed in a flexed position. The hot, dry, desert sand came into direct contact with the skin and often so completely arrested the process of decay that the hair, skin and soft parts are entirely preserved. This phenomenon of natural preservation was probably made known to the Egyptians through the ravages of grave-robbers whose depredations exposed the bodies to view. The discovery that the corpses of the dead did not suffer corruption undoubtedly strengthened, perhaps originated, the belief in the physical survival of the dead, which underlies the practice of mummification throughout the historic period, and prompted the ampler provision of food, utensils and other objects necessary to physical life which were buried with the dead. As the number of objects placed in the grave increased, the grave itself had to be more spacious in order to accommodate these larger supplies. But the burial of the dead in roomier graves or in constructed tombs in which the corpse, no longer embedded in desiccating sand, was in a space filled with air which assisted decomposition, defeated the very object that had inspired the more lavish equipment. The body decayed, and the dead man did not survive to enjoy the objects with which he was surrounded. Thus arose the attempt to achieve by art the preservation of the body which unaided nature could no longer accomplish in the larger tombs.

Development of Mummification.—It is probable that attempts at mummification were being made at the time of the 1st dynasty, but the earliest evidence of such attempts is afforded by a mummy of the 2nd dynasty, which was lying in a coffin in a flexed position, and was wrapped in a complex series of bandages, the innermost of which were corroded by the action of some preservative (probably crude natron) that had been applied to the skin (*Report, British Association*, Dundee, 1912, p. 612). Similarly treated bodies belonging to the 3rd and 4th dynasties have been discovered. By the time of the 5th dynasty considerable advances had been made. The body was now laid in the extended position and the internal organs were removed through an incision in the left flank, the vacant cavity being filled with linen and resin. The outer wrappings were saturated with resin and the form of the body was then moulded into shape, the details of the features being carefully modelled and emphasized by means of paint (*Journ. of Egyptian Archaeology*, i., 1914, p. 192). During the Middle Kingdom, the art of embalming deteriorated somewhat, for, owing to the less lavish use of resin and to imperfect desiccation, the mummies of this period are usually very fragile and ill-preserved. There is definite evidence that at this period the custom of macerating the body in a salt-bath had been introduced, but no attempt had as yet been made to remove the brain.

In the New Kingdom (18th–20th dynasties) numerous improvements in method were introduced. The brain was removed by forcing a passage into the skull, a better method of desiccation was used which preserved the tissues, and greater skill had been acquired in the preparation and application of the resinous preservative material with which the body was treated. Mummies of many of the kings and other members of the royal family of this period have survived, and although they have all been mutilated by tomb-robbers, many of them are excellent specimens of the embalmer's art (G. Elliot Smith, *The Royal Mummies*, 1912).

The order of events in the process of making a mummy was this. The corpse was taken to a specially erected tent or kiosk, where the operator first extracted the brain, and opened the body by an incision in the left flank. Through this incision all the viscera were removed with the exception of the heart, which was carefully left *in situ*. The body-cavity having been washed out, the corpse was doubled into the smallest possible compass and placed in a large jar filled with a solution of salt or natron that reached to the level of the neck. In this jar the body remained for several weeks, during which time the fatty matter was dissolved away, and the whole of the epidermis peeled off, except from the head which was not immersed, and from the fingers and toes where the skin had been previously cut so as to form natural finger-stalls or thimbles of skin in order to retain the nails. Threads or wires were wound round the digits, or metal sheaths placed upon them in order to prevent the nails from becoming detached and lost. The body was then taken out of the jar, washed, straightened and desiccated. The final stages in the process involved the packing of the body-cavity and skull with preservatives, plastering the body all over with a paste made of resin and fat, and wrapping it in a complex series of bandages. The internal organs were separately treated and placed in four vases known as the "Canopic Jars." The whole process occupied 70 days (*Journ. of Egyptian Archaeology*, xiii., 1927, pp. 40–49).

During the 21st and 22nd dynasties the art of mummification reached its highest pitch of perfection. In order to make the body more life-like, an elaborate system of introducing packing material *under* the skin was devised. A schematic series of incisions was made in various parts of the body, and through these sand, mud, or other material was forced into the space between the skin and the underlying muscular tissue. The material was distributed and moulded into shape, and the shrunken contours of the body were thus plumped out into the form they had assumed during life. The use of canopic jars was discontinued, and the viscera were made into linen parcels and replaced in the body. The mummy was painted all over with red-ochre, the lips and cheeks were rouged, artificial eyes were inserted, and, in short, every care was taken not only to preserve the body but to make it complete and life-like. This distinctive method of embalming was first described by Prof. Elliot Smith from the examination of 44 mummies of the period (*Contribution to the Study of Mummification*, 1906). Since then numerous other specimens of the same kind have been examined. After this period the art declined and, although well made mummies of the later periods are occasionally found, the embalmer's craft had become superficial and slipshod, and less care was devoted to the body than to the arrangement of the superficial bandages so as to give the mummy a presentable exterior. In the Ptolemaic period, the body was usually merely treated with molten resin, which destroyed the tissues: the resulting mummy was a mere cast of the contours of the body. During the 26th dynasty and after, mummies were sometimes eviscerated *per anum* instead of by the usual flank-incision. Mummification survived the advent of Christianity by several centuries. The bodies of this period were not eviscerated or treated with resin but packed in large quantities of common salt, and are usually well preserved (*Archaeological Survey of Nubia, Report for 1907–08*, vol. ii., pp. 194–220, 1910).

Objects of Mummification.—Throughout the period of more than 30 centuries during which mummification was practised in Egypt, the embalmers had two definite objects in view: first, the preservation of the body from decay; and, secondly, the perpetuation of the personal identity of the deceased. During the Pyramid Age the features of the mummy were painted on the outer wrappings, and in some cases a thin layer of plaster was applied to the head and the features painted upon it. In the 11th dynasty, the face and wig were modelled in cartonage, and this head-piece was placed upon the head of the mummy. The use of cartonage masks lasted until Ptolemaic times, but out of it was early evolved the anthropoid coffin, on which the features, dress and ornaments of the mummy were elaborately detailed. In Roman times, painted portrait-panels were employed (Petrie, *The Hawara Portfolio,* 1913). All these measures had one object—the preservation of the dead man's personal identity. That the idea underlying mummification was physical survival is further indicated by the magical ceremonies to which the finished mummy was subjected. These ceremonies, which are usually known as "Opening the Mouth," had for their object the reanimation of the mummy by restoring to it the faculties of which death had deprived it. By means of magical instruments and the recitation of formulae, the eyes, mouth and ears of the dead man were opened in order that he might once more see, speak, eat and hear. The use of his limbs was restored that he might move and walk, and amulets were used to stimulate the functions of the heart, the spine and the blood. Moisture and warmth were restored to the mummy by the ceremonial use of incense and libations. The funerary banquet which followed was envisaged, not as spiritual food for the soul, but materialistically as physical sustenance to be consumed by the mummy with its restored faculties.

Just as many of the drugs used in ancient Egyptian medicine, even when wholesome and rational, were originally introduced into the pharmacopoeia for purely magical reasons, so the use of natron, salt and resin, all of which are excellent preservatives, was probably first employed in mummification because these substances were credited with life-giving or life-preserving properties. Natron was used in the daily ceremonies for the rebirth of the sun-god, the life-giving power of salt was a tradition which survived till Classical times (*cf.* Plutarch, *Symposiacs,* v. 10), and resin was believed to be the blood or some other bodily emanation of Osiris. When therefore the necessity for artificial preservation of the dead first became apparent, it was natural that the attempt to confer or prolong life should have taken the form of applying to the corpse substances which were believed to possess divine or magical potency to that end. Bitumen was not used by the Egyptians for embalming. The staple material in all periods was resin, and the fact that resin often has a lustrous pitch-like appearance probably gave rise to the assertion expressed by Strabo (xvi., ii., 45) and repeated by modern writers that the Egyptians used bitumen for their mummies. Modern chemical analysis has failed to discover any trace of bitumen in hundreds of samples of various periods (A. Lucas, *Preservative Materials used by the Ancient Egyptians,* 1911). Neither Herodotus (ii., 85–88) nor Diodorus Siculus (i., 91), in their well known accounts of Egyptian embalming, makes any reference to bitumen. Their accounts of mummification are on the whole correct although seriously wrong in certain details.

Mummified Animals.—In relatively late periods the Egyptians mummified various sacred animals. Large quantities of mummified cats and dogs have been found, but especially elaborate was the ritual employed in embalming the Apis bulls (*Zeitschrift f. äg. Sprache,* lvi., 1920, pp. 1–33), and their tombs and gigantic sarcophagi are familiar to visitors to Egypt. Amongst the birds, the ibis, falcon, owl and others have been found, likewise the preserved remains of various reptiles (especially crocodiles) and of fishes. Joints of meat and trussed poultry were mummified and provided with wooden coffins shaped to fit them. The systematic study of the technique of animal mummification has yet to be made.

Geographical Distribution.—Mummification in various forms has had a wide geographical distribution. In some areas, the custom has long been extinct and only tradition remains to attest its former practice, but in others it survived until more recent times, or still persists in a debased form. In studying the technique of mummification in countries from which actual mummies have been obtained, it is interesting to find that many of the arbitrary details of Egyptian procedure are revealed. The examination of specimens from the Canary Islands, for instance, has revealed the fact that the Guanches employed certain methods which are distinctive of the Egyptian technique of the 21st dynasty (*see* p. 954). They made incisions for packing material under the skin, the sites of these incisions closely corresponding with those of the 21st dynasty Egyptian mummies, and there is a similar distribution of sandy mud in the tissues. In some cases at least, the viscera, which were always removed through a flank-incision, were made into parcels and returned to the body. The epidermis was removed from the whole body, but carefully retained on the fingers and toes, the nails being tied on in the characteristic Egyptian fashion (*Proc. Royal Society of Medicine,* xx., pp. 832–842, 851–854, 1927). Again, in the Islands of Torres Straits, mummification was practised until recent years. The viscera were removed through a flank-incision, or by the perineum, the brain was extracted, the body painted with red-ochre and provided with artificial eyes. The thimbles of skin on the fingers and toes were cut, but they were pulled off, and thus stultified the object for which the Egyptians devised them (*Annals of Archaeology and Anthropology,* xi., pp. 87–94, 1924). In Australia, mummification has survived in a debased form. The bodies are flexed and are often painted with red-ochre, and in some cases the epidermis is carefully removed from the body even when it is destined for cremation immediately afterwards. In North, Central and South America mummies have been found in various localities but the most numerous are those of the Inca civilization from Venezuela, Colombia, Ecuador, Bolivia and Peru. It has generally been asserted that the preservation of these Inca mummies is due to natural properties of the soil and climate, and not to artificial measures. Whilst the natural conditions in many localities certainly favour preservation, the circumstances in which many of the mummies have been discovered, closely wrapped in dense coverings and tightly corded, show that they must have been artificially desiccated before burial. The wrappings prevent contact of the body with the desiccating influence of the soil, and the coverings moreover closely embrace the shrunken contours of the corpse. In many instances mummies have been found which prove to have been eviscerated *per anum* or by an incision in the trunk, and others again are thickly coated with preservative material. Further, Inca mummies are often painted red, and specimens have been examined in which the epidermis had been removed from the whole body except the fingers and toes. The occurrence of such arbitrary details of Egyptian technique, especially as they often serve no useful purpose, in mummies from widely separated countries, supports the hypothesis that mummification, of Egyptian origin, spread with various other cultural elements from Egypt. (*Journ. Royal Anthropological Inst.* lviii., Pt. 1, 1928.)

Mummy as a Drug.—The belief that Egyptian mummies were prepared with bitumen or asphalt led to the virtues of that substance being transferred to bodies that had been mummified. Throughout the Middle Ages, and until the 18th century, mummies were exported to Europe for sale in the apothecaries' shops, and the material obtained by pounding them was reputed to have great medicinal virtue. In course of time it was forgotten that the supposed value of mummy was due to asphalt, and the virtue was transferred to bodies themselves. This led to the manufacture of spurious "mummy" from the bodies of felons and suicides, and the term was finally applied to medicated flesh in general. In spite of the denunciation of such eminent physicians as Paré, the traffic in mummy was continued until the 18th century, and the substance is frequently mentioned in the "dispensatories" of the period. In the East, mummy is still sold in the drug-bazaars (*Proc. Royal Society of Medicine,* xxi., pp. 34–39, 1927).

MUMPS (syn. *Cynanche parotidaea, parotitis;* also, "the branks"), a specific infectious disease caused by a filter-passing virus (*q.v.*), characterized by inflammatory swelling of the parotid and other salivary glands, frequently occurring as an epidemic, and affecting mostly young persons. The disease generally sets in with symptoms of a slightly febrile cold; soon followed by swelling and stiffening in the region of the parotid gland in front of the ear. The swelling speedily increases and spreads towards the neck and under the jaw, involving the numerous glands in that locality. The condition is often bilateral. Pain is seldom severe, nor is there much redness or any tendency to suppuration. There is, however, great interference with mastication and swallowing. After four or five days the parts return to their normal condition. During convalescence there occasionally occur swelling and tenderness in other glands, such as the testicles in males (*orchitis*), and the mammae or ovaries (*oöphritis*) in females, and possibly involvement of the pancreas, but these are of short duration and usually of no serious significance. Mumps is in general a mild disease, and requires no special treatment.

MUN, ADRIEN ALBERT MARIE DE, COUNT (1841–1914), French politician, was born at Lumigny (Seine-et-Marne), on Feb. 28, 1841. He entered the army, saw much service in Algeria (1862), and took part in the fighting around Metz in 1870. A fervent Roman Catholic, he advocated a type of Christian Socialism. His eloquence made him the most prominent member of the Cercles Catholiques d'Ouvriers. He resigned his commission (Nov. 1875), and in the following February stood as Royalist and Catholic candidate for Pontivy which he represented from 1876 to 1910. He was for many years the most conspicuous leader of the anti-Republican party. "We form," he said on one occasion, "the irreconcilable Counter-Revolution." It was chiefly through his influence that the support of the Royalist party was given to General Boulanger. But as a faithful Catholic he obeyed the encyclical of 1892, and declared his readiness to rally to a Republican Government, provided that it respected religion. In 1897 he succeeded Jules Simon as a member of the French Academy. He died at Bordeaux on Oct. 6, 1914.

He wrote *La loi des suspects* (1901); *Contre la séparation* (1905); *La guerre de 1914* (1915); *Discours* (1888–1904, 7 vols.). *See* Giraud, *Un grand Français: Adrien de Mun* (1918).

MUN, THOMAS (1571–1641), English writer on economics, was the third son of John Mun, mercer, of London. As a member of the committee of the East India company, and of the standing commission on trade, appointed in 1622, he was a prominent figure in mercantile circles, and well qualified to discuss current economic problems. In 1621 he published *A Discourse of Trade from England unto the East Indies,* in which he defended the East India company from the attacks made by Thomas Malynes, who in the vein of the early mercantilists asserted that the export of bullion was harmful to English trade. Mun argued that so long as exports exceeded imports, the drain of specie from a country had no significance, an argument which he further developed in his *Discourse on England's Treasure by Forraigne Trade,* published posthumously in 1664. In this most important work, Mun gave the first clear and vigorous statement of the theory of the balance of trade.

MUNCH, EDWARD (1863–), Norwegian painter, was born on Dec. 12, 1863, at Löten, Hedemark. He went to Christiania (Oslo) at an early age and studied at the royal school of drawing under Krohg who introduced him to the naturalistic school of painting. The genius of Munch, however, reacted against this teaching. He was more inclined to express feelings inspired by a troubled mind than impressions engendered by reality. The most famous work of this early period is "Spring" (1899), one of the gems of the National Gallery at Oslo. In the beginning of the 'nineties, the undercurrent of mental agitation broke through in all its power, and in a number of works (mostly in the Oslo National Gallery), Munch revealed an extraordinary sensitiveness, displayed alike in the subjects of his pictures and the artistic method of execution which he employed. From the beginning of the 20th century Munch's art assumed a more realistic character. This is particularly evident from his landscapes of this period, the outstanding features of which are vigorous plainness and impressive colouring. In 1913 Munch completed the fresco decorations of the University Festival Hall at Oslo.

See G. Schliefler, *Das graphische Werk E. Munchs* (1907); C. Glaser, *Edward Munch* (1922).

MUNCHAUSEN, BARON. This name is famous in literary history on account of the amusingly mendacious stories known as the *Adventures of Baron Munchausen.* In 1785 a shilling book of 49 pages was published in London, called *Baron Munchausen's Narrative of his Marvellous Travels and Campaigns in Russia.* No copy is known to exist, but a second edition (apparently identical) was printed at Oxford early in 1786. The publisher was a certain Smith, and he then sold it to another bookseller named Kearsley, who brought out in 1786 an enlarged edition, with illustrations under the title of *Gulliver Reviv'd: the Singular Travels, Campaigns, Voyages and Sporting Adventures of Baron Munnikhouson, commonly pronounced Munchausen; as he relates them over a bottle when surrounded by his friends.* Four editions rapidly succeeded, and a free German translation by the poet Gottfried August Bürger, from the fifth edition, was printed at Göttingen in 1786. The seventh English edition (1793), is the usual text. In 1792 a *Sequel* appeared, dedicated to James Bruce, the African traveller, whose *Travels to Discover the Nile* (1790) had led to incredulity and ridicule. Munchausen increased in popularity and was translated into many languages. Continuations were published, and new illustrations provided (*e.g.,* by T. Rowlandson, 1809; A. Crowquill, 1859; A. Cruikshank, 1869; the French artist Richard, 1878; Gustave Doré, 1862, W. Strang and J. B. Clark, 1895).

The original author was Rudolf Erich Raspe (*q.v.*). Raspe had apparently become acquainted at Göttingen with Hieronymus Karl Friedrich, Freiherr von Münchausen, of Bodenwerder in Hanover. This Freiherr von Münchausen (1720–97) had been in the Russian service and served against the Turks, and on retiring in 1760 to his estates used to amuse himself by relating extraordinary instances of his prowess as soldier and sportsman. His stories became a byword among his circle, and Raspe, when hard up for a living in London, utilized the suggestion for his little brochure. Raspe can only be held responsible for the nucleus of the book; the additions were made by bookseller's hacks, suggestions being taken from Baron de Tott's Memoirs (Eng. trans. 1785), the aeronautical feats of Montgolfier and Blanchard and any topical "sensations" of the moment, such as Bruce's explorations in Africa. Munchausen, as we have it, is therefore a medley of material of all ages, from Lucian's *Vera Historia* and Renaissance *facetiae* to contemporary travels, real and imaginary.

See the introduction by T. Seccombe to Lawrence and Bullen's edition of 1895. Carl Muller-Fraureuth's *Die deutschen Lügendichtungen auf Münchausen* (1881) and Griesbach's edition of Bürger's translation (1890).

MÜNCH-BELLINGHAUSEN, ELIGIUS FRANZ JOSEPH, FREIHERR VON (1806–1871), Austrian poet and dramatist (who wrote under the pseudonym "Friedrich Halm"), was born at Cracow on April 2, 1806, the son of a district judge. In 1840 he became Regierungsrat, in 1845 Hofrat and custodian of the royal library, in 1861 life member of the Austrian Herrenhaus (upper chamber), and from 1869 to 1871 was intendant of the two court theatres in Vienna. He died at Hütteldorf near Vienna on May 22, 1871. Münch-Bellinghausen's dramas, among

them notably *Griseldis* (1835; publ. 1837; 11th ed., 1896), *Der Adept* (1836; publ. 1838), *Camoens* (1838), *Der Sohn der Wildnis* (1842; 10th ed., 1896), and *Der Fechter von Ravenna* (1854; publ. 1857; 6th ed., 1894), are well written and cleverly constructed, and were popular in their day.

See F. Pachler, *Jugend und Lehrjahre des Dichters F. Halm* (1877).

MUNCIE, a city of eastern Indiana, U.S.A., 54 m. N.E. of Indianapolis, on the White river, at an altitude of 950 ft.; the county seat of Delaware county. It has a municipal airport 1½ m. from the business district, and is served by the Big Four, the Chesapeake and Ohio, the Nickel Plate, the Pennsylvania, and three belt-line railways, and by numerous interurban trolleys and motor-bus lines. The population was 36,524 in 1920 (92% native white) and was 46,548 in 1930 by the Federal census. It is a well built city, occupying 7 sq.m. of level ground, with an assessed valuation for 1927 of $59,980,220. The residential sections are beautiful with trees and wide lawns; zoning regulations are in force; and a boulevard along the river is under construction (1928). The Ball Teachers' college in the western part of the city (named after the Ball brothers, manufacturers of Muncie, who since 1918 have given about $500,000 to the institution) is the eastern division of the State Normal school. It has a plant valued at $2,000,000 and an enrolment of about 1,250. Muncie has a wide trading territory, embracing 22 counties of eastern Indiana and western Ohio. Its manufacturing industries are many and varied, with an output in 1927 valued at $52,381,207. The principal products are automobile parts, tops, bodies, hoods and castings; storage batteries, glass fruit jars and jelly glasses, insulators and bottles; and steel wire and cable and articles made from them. The combined resources of the banks amounted in 1927 to $15,000,000. Muncie was founded about 1833, incorporated as a town in 1847 and as a city in 1865. Its name (originally Munseytown, but changed by the state legislature in 1845) commemorates the Munsees, a division of the Delaware Indians, who formerly lived along the White river.

MUNDA, BATTLE OF (45 B.C.). Whilst Caesar was campaigning in Africa, Pompey's cause was revived in Spain by his sons Gnaeus and Sextus who had recruited a large army. From Africa Caesar returned to Rome, and towards the end of 46 B.C. once again proceeded to Spain where he suffered a reverse on the river Baetis; but, worsting Gnaeus Pompey at Soricaria, that general retired southwards towards Carteia; Caesar, however, headed him off and forced him to retrace his steps to Munda.

The site of Munda is undecided; some historians consider that it is the same as modern Monda, but the description of the battle renders this unlikely. It was probably north of the river Singulis in the neighbourhood of Montilla.

The town of Munda was situated on a hill, and under its walls Cn. Pompey camped on March 15, 45 B.C. The next day, Caesar arrived and entrenched a camp near a small stream some five miles away. On the 17th, learning that Gn. Pompey had been standing in battle array for some time he ordered his standards to be raised. The two camps were separated by an undulating plain traversed by a stream, and on this plain and behind the stream Caesar marshalled his army, hoping that Gn. Pompey would come down from the hill of Munda and fight him in the open. Gn. Pompey was in command of some 50,000 men, his position was exceptionally strong, for any attack on him would have to be made up-hill and over marshy ground.

Caesar's army numbered some 40,000, and as Gn. Pompey refused to come down from the hill he advanced towards him. On reaching the stream he halted his line, and pointed out to his officers the disadvantage of attacking up-hill. This becoming known to the men, considerable insubordination was displayed, as they felt certain of victory. Caesar thereupon ordered the advance to be continued. This halt, however, had induced Pompey to believe that Caesar had hesitated through fear, which was the case, and plucking up courage he moved his line down the hill, but not so far from Munda that he could not retire to it if defeated.

When the lines met the greatest enthusiasm was shown on both sides. Caesar's legions charging up the hill with great gallantry were met by a storm of *pila* (javelins). Pompey's men, remembering the terrible slaughter at Thapsus, fought with determination and fury. The flight of javelins was followed by a charge which struck Caesar's front "like a ram" and staggered his line. The clinch then took place, and little by little Caesar's cohorts were pushed back. The situation now became extremely critical for Caesar was some five miles from his camp, and should his line break, annihilation must follow. Seizing a sword and a shield he rushed forward in the front rank before the ensigns, and by his personal example stimulated the *moral* of his men.

As evening approached both sides had exhausted their reserves, the auxiliaries had left the field, there was no chance of manoeuvring except by cavalry, and though both sides had a considerable number of horsemen, apparently no such manoeuvre was made—very few Roman generals ever understood the use of this arm. At length, as the situation became still more critical, Caesar turned to his veteran Xth legion and cried: "Are you not ashamed to deliver your general into the hands of boys?" Stung by this taunt the Xth legion once again charged forward driving back Pompey's left, and compelling him to draw on his right in order to reinforce it. Caesar's cavalry then fell upon the weakened right wing, which was badly shaken. This apparently stimulated Caesar's Numidian cavalry into action, for they moved round Pompey's right wing towards his camp. Labienus, who commanded this wing, despatched five cohorts to head them off; this rearwards movement was mistaken by the Pompeian army as a general withdrawal. Thereupon the line broke and fell back on Munda in confusion. At last Caesar's 8,000 horsemen were launched, and 30,000 of the enemy were slaughtered. Caesar's losses were 1,000 killed and 500 wounded.

See PHARSALUS. (J. F. C. F.)

MUNDĀS. The Mundā (*Muṇḍā*) family is the least numerous of the linguistic families of India. It comprises several dialects spoken in the two Chota Nagpur plateaux, the adjoining districts of Madras and the Central Provinces, and in the Mahadeo hills. Santālī, Mundārī, Bhumij, Birhâr, Kōḍā, Hō, Tūrī, Asurī and Korwā are only slightly differing forms of one and the same language, which can be called Kherwārī, a name borrowed from Santālī tradition. Kherwārī is the principal Mundā language, and quite 88% of all the speakers of Mundā tongues belong to it. The Korwā dialect, spoken in the western part of Chota Nagpur, connects Kherwārī with the remaining Mundā languages. Of these it is most closely related to the Kūrkū language of the Mahadeo hills in the Central Provinces. Kūrkū, in its turn, in important points agrees with Khariā and Juāng, and Khariā leads over to Savara and Gadabā. The two last-mentioned forms of speech, which are spoken in the north-east of the Madras Presidency, have been much influenced by Dravidian languages.

The Mundā dialects are, as a rule, only found in the hills and jungles, while the plains and valleys are inhabited by people speaking some Aryan language. When brought into close contact with Aryan tongues Mundā forms of speech have been partly superseded by Aryan dialects. Thus some Aryanized tribes in northern India have formerly belonged to the Mundā stock. Such are the Cheros of Behar and Chota Nagpur, the Kherwars, who are found in the same localities, in Mirzapur and elsewhere, the Savaras, who formerly extended as far north as Shahabad, and others. An old Mundā element is present in some Tibeto-Burman dialects spoken in the Himalayas from Bashahr eastwards.

They are short, dark skinned, broad nosed, with curly hair, with medium to long heads—features possessed by the jungle tribes of southern India, the Veddas, Sakai, etc.

The Mundā family of languages in India proper belongs to the Austro-Asiatic division of the Austric family. They must have been settled in India from a very early period. The Sabaras, the ancestors of the Savaras, are already mentioned in old Vedic literature.

The Mundā languages abound in vowels, and also possess a richly developed system of consonants. They avoid beginning a word with more than one consonant. They shorten short consonants at the end of words. The usual stopped consonants—viz., *k*, *c* (*i.e.*, English *ch*), *t* and *p*—are formed by stopping the current of

breath at different points in the mouth, and then letting it pass out with a kind of explosion. In the Mundā language this operation can be abruptly checked half-way, so that the breath does not touch the organs of speech in passing out. The result is a sound that makes an abrupt impression on the ear, and has been described as an abrupt tone. Such sounds are common in the Mundā languages. They are usually written *k'*, *c'*, *t'* and *p'*. Similar sounds are also found in the Mōn-Khmēr languages and in Indo-Chinese.

The vowels of consecutive syllables to a certain extent approach each other in sound. Thus in Khērwārī the open sounds *å* (nearly English *a* in all) and *ä* (the *a* in care) agree with each other and not with the corresponding close sounds *o* (the *o* in pole) and *e* (the *e* in pen). The Santālī passive suffix *ok'* accordingly becomes *åk'* after *ä* or *å*; compare *sän-åk'*, go, but *dal-ok'*, to be struck.

Words are formed from monosyllabic bases by means of various additions, suffixes (such as are added after the base), prefixes (which precede the base) and infixes (which are inserted into the base itself). Suffixes play a great rôle in the inflexion of words, while prefixes and infixes are of greater importance as formative additions. Compare Kurku *k-ōn*, Savara *ōn*, son; Kharia *ro-mong*, Kherwārī *mū*, nose; Santālī *bor*, to fear; *bo-to-r*, fear; *dal*, to strike; *da-pa-l*, to strike each other.

The various classes of words are not clearly distinguished. The same base can often be used as a noun, an adjective or a verb. The words simply denote some being, object, quality, action or the like, but they do not tell us how they are conceived.

Inflexion is effected by means of additions to the unchanged base. There is no grammatical distinction of gender. Nouns can be divided into two classes, viz., those that denote animate beings and those that denote inanimate objects respectively. There are three numbers—the singular, the dual and the plural. There are no real cases, at least in the most typical Mundā languages. The direct and the indirect object are indicated by means of additions to the verb. Relations in time and space are indicated by means of suffixes. The genitive, which can be considered as an adjective preceding the governing word, is often derived from such forms denoting locality. Compare Santālī *hår-rä*, in a man; *hår-rän*, of a man. Higher numbers are counted in twenties. The pronouns have double sets of the dual and the plural of the pronoun of the first person, one including and the other excluding the person addressed. There are also short forms, used as suffixes and infixes, which denote a direct object, an indirect object, or a genitive. The pronoun "that" in Santālī has different forms to denote a living being, an inanimate object, something seen, something heard, and so on. There is no relative pronoun, the want being supplied by the use of indefinite forms of the verbal bases, which can in this connection be called relative participles.

Every independent word can perform the function of a verb, and every verbal form can, in its turn, be used as a noun or an adjective. The bases of the different tenses can therefore be described as indifferent words which can be used as a noun, as an adjective, and as a verb, but which are in reality none of them. Each denotes simply the root meaning as modified by time. Thus in Santālī the base *dāl-ket'*, struck, which is formed from the base *dal*, by adding the suffix *ket'* of the active past, can be used as a noun (compare *dal-ket'-ko*, strikers, those that struck), as an adjective (compare *dal-ket'-hår*, struck man, the man that struck), and as a verb. In the last case it is necessary to add an *a* if the action really takes place; thus, *dal-ket'-a*, somebody struck.

The pronominal affixes to indicate direct and indirect object are inserted before the assertive particle *a*. Thus the affix denoting a direct object of the third person singular is *e*, and by inserting it in *dal-ket'-a* we arrive at a form *dal-ked-e-a*, somebody struck him. Similar affixes can be added to denote that the object or subject of an action belongs to somebody. Thus Santālī *håpån-iñ-e dal-ket'-tako-tiñ-a*, son-my-he struck-theirs-mine, my son who belongs to me struck theirs.

A single verbal form often corresponds to a whole sentence or a series of sentences in other languages. The most developed Mundā languages possess different bases for the active, the middle and the passive; there are different causal, intensive and reciprocal bases, which are conjugated throughout, and the person of the subject is often indicated in the verb, which is, however, quite regular throughout.

See *Linguistic Survey of India*, vol. iv., p. i. and vol. i., 1927.

MUNDAY (or MONDAY), **ANTHONY** (*c.* 1553–1633), English dramatist and miscellaneous writer, son of Christopher Monday, a London draper, was born in 1553–1554. He had already appeared on the stage when in 1576 he bound himself apprentice for eight years to John Allde, the stationer, but in 1578 he was in Rome. In spite of the opening lines of his *English Romayne Lyfe* (1582), he must be regarded, if not as a spy at least as a journalist whose copy was the designs of the English Catholics in France and Italy. He says that in Paris, under a false name, as the son of a well-known English Catholic, Munday gained recommendations which secured his reception at the English College in Rome. He gives a detailed account of the routine of the place, of the dispute between the English and Welsh students, of the carnival at Rome, and finally of the martyrdom of Richard Atkins (? 1559–1581). He returned to England in 1578–1579, and became an actor again, being a member of the Earl of Oxford's company between 1579 and 1584. He brought back material for five anti-popish pamphlets, among them the tract entitled *A Discoverie of Edmund Campion and his Confederates*, the first part of which was read aloud from the scaffold at Campion's death in December 1581. The tract *A True Report of . . . M. Campion* (1581), which says that he "played extempore" and was hissed off the stage, is a reply. His political services against the Catholics were rewarded in 1584 by the post of messenger to her Majesty's chamber, and from this time he seems to have ceased to appear on the stage. In 1598–1599, when he travelled with the earl of Pembroke's men in the Low Countries, it was in the capacity of playwright to furbish up old plays. He devoted himself to writing for the booksellers and the theatres, compiling religious works, translating *Amadis de Gaule* and other French romances, and putting words to popular airs. He was the chief pageant-writer for the City from 1605 to 1616, and it has been conjectured that he supplied most of the pageants between 1592 and 1605. It is by these entertainments of his, which rivalled in success those of Ben Jonson and Middleton, that he won his greatest fame. He was buried in St. Stephen's, Coleman street, on Aug. 10, 1633.

Of the eighteen plays between the dates of 1584 and 1602 which are assigned to Munday in collaboration with Henry Chettle, Michael Drayton, Thomas Dekker and other dramatists, only four are extant.

The completest account of Anthony Munday is T. Seccombe's article in the *Dict. Nat. Biog.* A life and bibliography are prefixed to the Shakespeare Society's reprint of his *John a Kent and John a Cumber* (ed. J. P. Collier, 1851). His two "Robin Hood" plays were edited by J. P. Collier in *Old Plays* (1828), and his *English Romayne Lyfe* was printed in the *Harleian Miscellany*, vii. 136 *seq.* (ed. Park, 1811). For an account of his city pageants *see* F. W. Fairholt, *Lord Mayor's Pageants* (Percy Soc., No. 38, 1843). *See* also *Modern Language Review*, 1909, 1913, 1920; M. St. C Byrne, *Anthony Munday and his Books* (1921); E. K. Chambers, *The Elizabethan Stage* (vol. iii., 1923); C. R. Hayes, *Anthony Munday's Romances of Chivalry* (1925).

MUNDELEIN, GEORGE WILLIAM (1872–), American cardinal, was born in New York city on July 2, 1872. He received his education at Manhattan college and St. Vincent seminary, Beatty, Pa., subsequently proceeding to Rome and studying theology at the Urban College of the Propaganda in that city. He was ordained priest on June 8, 1895, at Rome, and became secretary to Bishop McDonnell of Brooklyn, N.Y., and pastor of the Lithuanian Church, being made chancellor of the diocese in 1897. He was appointed auxiliary bishop of Brooklyn, with the titular see of Loryma, on Sept. 2, 1909, and founded and became president of the Seminary of the Immaculate Conception in 1913. He became archbishop of Chicago on November 30, 1915, and was created a cardinal by Pope Pius XI. on March 24, 1924. He was a prominent figure at the Eucharistic Congress held in Chicago in June, 1926.

See J. J. Walsh, *Our American Cardinals* (1926).

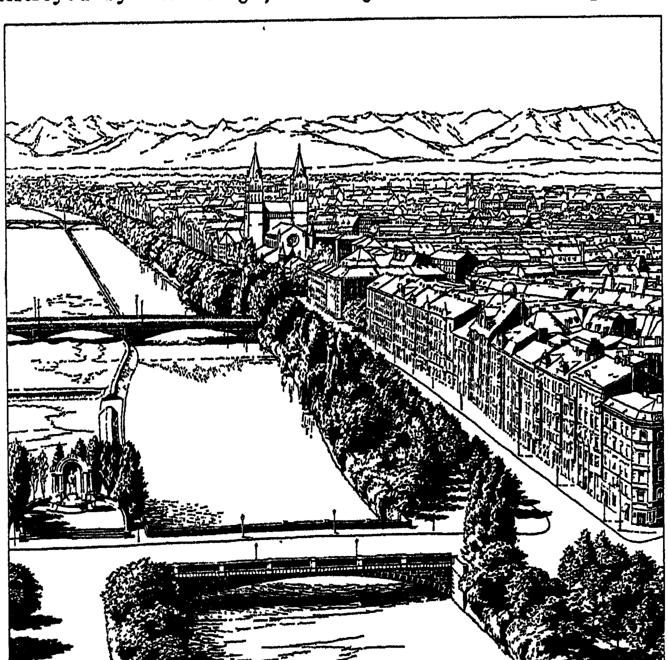
MÜNDEN, a town of Germany, in the Prussian province of Hanover, situated at the confluence of the Fulda and the Werra, 21 m. N.E. of Cassel by rail. Pop. (1925) 11,983. Münden, often called "Hannoversch-Münden" (*i.e.*, Hanoverian Münden), to

distinguish it from Prussian Minden, was founded by the landgraves of Thuringia, and passed in 1247, when it received municipal rights, to the house of Brunswick. A few ruins of its former walls still survive. The churches include that of St. Blasius (14th–15th centuries) and the 13th-century Church of St. Aegidius. The town hall (1619), and the ducal castle, built about 1570, and rebuilt in 1898, are the principal secular buildings. The manufactures include rubber, leather, and lead piping with trade in timber.

MUNHALL, a borough of Allegheny county, Pennsylvania, U.S.A., on the Monongahela river, eight m. S.E. of Pittsburgh, adjoining Homestead (*q.v.*). It is served by the Pennsylvania Railroad, and for freight by the Pittsburgh and Lake Erie and the Union. Pop. (1920) 6,418 (29% foreign-born white); 12,995 in 1930 by the Federal census. It is an integral part of the Homestead district, the steel mills lying largely within its limits. The borough was incorporated in 1901.

MUNICH, capital of the republic of Bavaria, and the fourth largest town in the German Republic, stands on the river Isar, 25 m. N. of the foot-hills of the Alps, about midway between Strasbourg and Vienna. Pop. (1925) 680,704. Owing to its lofty site (1,700 ft.), the climate is changeable, and its temperature ranges from a January average of 27° F to a July average of 63° F. The annual rainfall is 35 in. Munich is the centre of an important network of railways connecting it directly with Strasbourg (for Paris), Cologne, Leipzig, Berlin, Rosenheim (for Vienna) and Innsbruck (for Italy via the Brenner pass).

The Villa Munichen or *Forum ad monachos,* so called from the monkish owners of the ground, was the site of a mint in 1158 and an emporium for salt coming from Hallein and Reichenhall. In 1255 Duke Louis made it his capital, having previously surrounded it with walls and a moat. The town was almost entirely destroyed by fire in 1327. In 1632 Munich was occupied by Gustavus Adolphus, and in 1705, and again in 1742, it was in possession of the Austrians.



BY COURTESY OF THE GERMAN STATE RAILWAYS
VIEW OF MUNICH FROM THE OBSERVATION TOWER OF THE GERMAN MUSEUM, SHOWING MOUNTAIN PEAKS AND THE BANKS OF THE RIVER ISAR

The old town forms a semicircle with its diameter towards the left bank of the river, while round its periphery has sprung up the greater part of modern Munich. The walls with which Munich was surrounded were pulled down in 1791, but some of the gates have been left. The most interesting is the Isartor and the Karlstor, restored in 1835 and adorned with frescoes.

The chief buildings were built in the 19th century and most of them have been erected after celebrated prototypes of other countries and eras. The architectural style which has been principally followed in the later public buildings is the Italian and French Rococo, or Renaissance, adapted to the traditions of Munich architecture in the 17th and 18th centuries. A large proportion of the most notable buildings in Munich are in two streets, the Ludwigstrasse and the Maximilianstrasse. At one end the former is terminated by the Siegestor, while at the other is the Feldherrenhalle (or hall of the marshals), a copy of the Loggia dei Lanzi at Florence. Adjacent is the church of the Theatines, containing the royal burial vault. The Maximilianstrasse extends from Haidhausen on the right bank of the Isar to the Max-Joseph Platz. At the east end it is closed by the Maximilianeum, adorned externally with large sculptural groups and internally with huge paintings representing scenes of world-history. Towards the west are the old buildings of the Bavarian national museum, the government buildings and the mint. On the north side of the Max-Joseph Platz lies the former royal palace. The Allerheiligen-Hofkirche, or court-church, is in the Byzantine style, with a Romanesque façade.

On the Frauenplatz in the centre of the old town stands the Frauenkirche, the cathedral church of the archbishop of Munich-Freising. It is imposing from its size, and interesting as one of the few examples of indigenous Munich art. On the adjacent Marienplatz are the 14th century town hall (restored in 1865), and the new town hall, a modern Gothic erection.

Among the other churches are St. Boniface, a copy of an early Christian basilica; the parish church of Au, in the Early Gothic style; and the church of St. John in Haidhausen, another fine Gothic structure. St. Michael's in the Renaissance style, erected for the Jesuits in 1583–95, contains the monument of Eugène Beauharnais by Thorwaldsen. St. Peter's is interesting as the oldest church in Munich (12th century).

The old Pinakothek, erected in 1826–36, contains a valuable collection of pictures by the earlier masters, the chief treasures being the early German and Flemish works and the unusually numerous examples of Rubens. Opposite stands the new Pinakothek, built 1846–53, devoted to works by painters of the last century. The Glyptothek, a building in the Ionic style, contains a valuable series of sculptures, extending from Assyrian and Egyptian monuments down to works by Thorwaldsen and other modern masters. The celebrated Aeginetan marbles are preserved here. The Schack Gallery is rich in works by modern German masters, and the Lotzbeck collection contains sculptures and paintings. Munich is associated with a school of German artists among whom may be mentioned von Klenze (1784–1864), the architect; Cornelius (1783–1867) and von Kaulbach (1804–74), the painters; and Schwanthaler, the sculptor.

The Bavarian national museum contains an ethnographical museum, and collections of fossils, minerals, physical and optical instruments and coins. The art union is the oldest and most extensive in Germany, while the observatory is equipped with instruments by Josef Fraunhofer.

The university, founded at Ingolstadt in 1472 and removed to Landshut in 1800, was transferred thence to Munich in 1826. On the Theresienwiese is situated the Ruhmeshalle or hall of fame, a Doric colonnade containing busts of eminent Bavarians.

Munich is the seat of the archbishop of Munich-Freising as well as of the general Protestant consistory for Bavaria. The town has long been celebrated for its artistic handicrafts, such as bronze-founding, glass-staining, silversmith's work, and wood-carving, while the astronomical instruments of Fraunhofer and the mathematical instruments of Traugott Lieberecht von Ertel (1778–1858) are also widely known. Lithography, invented at Munich at the end of the 18th century, is extensively practised. Other industrial products include wall-paper, railway plant, machinery, gloves, rubber, margarine, chemicals, various motors, pianos and artificial flowers.

There is an English book on Munich by H. R. Wadleigh (1910).

MUNICIPAL HOUSING: *see* TOWN AND CITY PLANNING and HOUSING.

MUNICIPALITY, a modern term now used both for a city or town which is organized for self-government under a municipal corporation, and also for the governing body itself. Such a corporation in Great Britain consists of a head as a mayor or provost, and of superior members, as aldermen and councillors, together with the simple corporators, who are represented by the governing body; it acts as a person by its common seal, and has a perpetual succession, with power to hold lands subject to the restrictions of the Mortmain laws; and it can sue or be sued. Where necessary for its primary objects, every corporation has power to make bylaws and to enforce them by penalties, provided they are not unjust or unreasonable or otherwise inconsistent with the objects of the charter or other instrument of foundation.

See BOROUGH, COMMUNE, CORPORATION, LOCAL GOVERNMENT, and, for the functions of the municipal government, the sections under the general headings of the different countries.

MUNICIPAL TRADING. Trading, either monopolist or in competition with private enterprise, *e.g.*, municipal authorities, is not properly defined as a branch of Socialism though the Socialist Parties alone have advocated it as part of a general policy. Certain of the most remarkable experiments have been undertaken under anti-Socialist direction, as in Blackpool where municipal enterprise caters for amusement, and Birmingham, which has a municipal bank.

Great Britain.—It is not possible to fix with certainty limits to the field of municipal trading. Industries of national extent, such as railways or coal mining, may be ruled out by nature, but the restricted field of municipal enterprise in Great Britain is largely due to the legal position. A Local Authorities Enabling Bill has been sponsored by the Labour Party but at present (1929) local authorities have powers only to undertake such enterprises as are specifically permitted to them by legislation, and any further developments require a special act of parliament, which is difficult to get. These acts almost always carry stipulations as to prices chargeable, utilization of profit and repayment of loans, which are more onerous than the usual practice of private industry, nor are they granted as a matter of course. For example, that municipal banking has not been undertaken outside Birmingham is due, not to any ill-success of the Birmingham city bank, but to the fact that the political complexion of Parliament was for years unfavourable to any solicitations for similar permissions elsewhere. A survey of the present field of municipal enterprise is given by the Ministry of Health *Report* of 1926 which divided the outstanding municipal loan debt (England and Wales) as follows:

	£
Housing and town planning	199,451,481
Water works	144,772,500
Highways and bridges	73,580,481
Electric light supply undertakings	58,699,552
Sewer and sewage disposal	46,211,403
Tramways and light railways	36,801,408
Elementary education	33,396,438
Gas works	24,728,978
Small holdings and allotments	19,738,815
Parks, pleasure grounds and open spaces	10,983,058

Roads, education, police (not given above) and park services are perhaps not to be classed as municipal trading.

The *water supply*, according to the *Municipal year book 1928*, is in the hands of about two-thirds of the country boroughs of England and Wales, of nearly all the non-county boroughs and of about half the urban districts. In the metropolitan area it is also in the hands of a public authority, the metropolitan water board. The following table gives the position of certain of the main undertakings according to the *Labour Year Book 1927*.

	Total capital expenditure from loans and other sources		Total capital repaid or in sinking fund, or provided by revenue	Total loans outstanding
	Up to end of 1923–24	During 1924–25		
	£	£	£	£
Birmingham	8,808,912	85,861	1,245,078	7,654,673
Bradford	5,572,135	41,363	550,258	1,443,117
Glasgow	5,188,634	56,729	2,695,924	2,574,824
Leeds	4,628,270	123,555	1,698,486	3,237,374
Liverpool	6,892,412	73,276	2,129,193	4,878,734
Manchester	10,179,664	374,995	3,216,360	7,331,698

Over 170 *tramway* undertakings in Great Britain are owned by municipal authorities. The following figures are given according to the *Return of Tramways, etc., Undertakings 1925–26.*

Capital expenditure	£76,761,999
Gross receipts	£23,918,662
Working expenses	£19,009,122
Net receipts	£ 5,269,042
Passengers carried	4,065,268,307
Car miles run	323,391,979

Nearly all these are run under special acts. The problems of intermunicipal co-ordination and the general problems arising out of trams will be found discussed under TRAMWAYS. Permission for municipal motor bus services has been less freely granted: only 66 towns had in 1927 a motor bus service of their own.

The shortage of *houses* after the World War caused the passing of measures which enabled municipal authorities to embark on housebuilding, with the encouragement of a subsidy from the Government. Under C. Addison's act of 1919 174,583 houses had been built by the beginning of 1928 and 39,186 under his Private Builders' Act. Of the 315,749 houses built under N. Chamberlain's 1923 act, the majority were provided by private enterprise; of the 161,363 built under J. Wheatley's 1924 act the majority were supplied by local authorities. This building was undertaken very largely with the advice and under the direction of Joint Town Planning Committees, of which there were 53 in England and Wales. For further details *see* HOUSING.

Under the item *Parks* notice should be taken of the increase in municipal golf courses (municipal tennis courts and other playing fields are almost universal). These are maintained by Birmingham (4 courses), Bournemouth (2), Brighton, Leeds, Leicester, Llandudno, London City Corporation, London County Council, Manchester, Margate, Nottingham (2), Portsmouth, Sheffield, Southend, Southport, Wallasey, Yarmouth and others.

In Scotland there are even more: Alloa, Arbroath, Berwick, Campbelltown, Carnoustie, Dornock, Edinburgh, Glasgow (3), Gourock, Greenock, Kilmarnock, Kinghorn, Kirkcaldy, Montrose (6), Musselburgh, Rothesay, St. Andrews (4), Troon (3) and others.

The following figures, selected from the *Municipal Year Book 1928*, refer to 4 of the most important municipal *gas* undertakings.

	Belfast	Birmingham	Edinburgh	Manchester
Date of origin	1874	1875	1888	1843
Total capital expenditure:				
(a) up to end of 1925–26	£1,856,944	£3,318,433	£2,509,621	£5,175,522
(b) in 1926–27	16,446	670,466	34,906	440,963
Total capital repaid or in sinking fund	1,010,579	2,027,613	1,544,796	3,267,146
Loans outstanding	1,079,056	2,698,381	999,731	2,309,186
Income 1926–27	838,914	999,658	792,297	1,792,164
Charges	3/4 cu.ft.	3/2–3/2 less 5% discount	3/6–4/6 cu.ft.	10d. per term within city: 10·67d. without

The position of municipal *electricity* has been complicated by the appointment of the national Electricity Commissioners and

the Central Electricity Board (*qq.v.*): under whose direction the electrical industry as a whole is to be systematised. At the end of March 1927, out of 623 authorized undertakings in Great Britain, 374 were those of local authorities. The provision of *markets and slaughterhouses* has rapidly increased since it was first legalized by the act of 1875. The reasons adduced are: excessive profits by private concerns, insanitary and dangerous conditions, cruelty to animals. The following figures (quoted in the *Labour Year Book, 1927*) indicate the position of 6 of the largest enterprises.

	Birmingham	Bradford	Glasgow	Leeds	Liverpool	Manchester
1. Date of acquisition or inauguration	1824	1866	1845	1842	1892	1846
Total capital expenditure from loans and other sources:						
2. Up to end of 1923–24	£453,510	£343,636	£452,600	£474,358	£302,083	£894,705
3. During 1924–25	13,045	6,167	2,751	4,295	..	..
4. Total capital repaid or in sinking fund or provided by revenue	370,451	227,703	228,839	237,733	276,519	600,076

UNITED STATES

Complete official reports are not available as to the extent of municipal trading in the United States. From unofficial but more or less dependable sources, however, the following table has been compiled, showing the state of the movement in the year 1928:—

Municipal Enterprises in the United States

Kind	No. of municipalities owning	Value of properties in about 200 of the largest cities
Water works	6,900[1]	$1,745,245,581[2]
Electric light and power	2,581[3]	137,910,381[2]
Gas plants	109[4]	..
Street railways	16[5]	68,626,475[5]
Markets	112[6]	43,592,143[2]
Ice plants, ferries, toll bridges, land, harbour services and farms[7]	..	684,144,697[2]
Total for the 200 cities given in official reports	..	$2,610,892,804[2]
Total—estimated	7,000	$3,000,000,000

[1]Estimated by the American Water Works Association, reported by C. W. Steffler in *Commerce and Finance* (Aug. 4, 1926); [2]U.S. Census, *Financial Statistics of Cities*, Table 19, p. 398 (1925); [3]U.S. Census, *Central Electric Light and Power Stations* (1922); [4]Brown's *Directory of American Gas Companies;* [5]U.S. Census, *Electric Railways*, pp. 236, 238 (1922); [6]U.S. Census, *Financial Statistics of Cities*, pp. 398 *seq.* (1925); [7]the Census report, *Financial Statistics*, p. 398 (1925) under the heading, "All other," lumps the receipts from several municipal service enterprises. On p. 48 of the same report there is an explanation that these receipts are principally from "ferries, toll bridges, harbour tollage and pilotage, land development, ice plants and farms." Of the large amount for New York city, $3,741,920 was received from ferry tolls and $328,273 from bridge tolls.

The only official figures available on municipal enterprises in the United States are those of the U.S. Census, and they cover only 247 cities. This includes only the larger cities—those having 30,000 population and over. As there are, in all, 15,692 cities, towns, villages and incorporated places in the United States, it is obvious that the census reports give a very incomplete picture of the situation. And especially so as several thousands of these smaller cities own and operate municipal waterworks, while the great majority of the 2,581 municipal light and power plants officially reported are in cities and towns of much less than 30,000 population. The total number of cities owning and operating municipal enterprises has been therefore estimated as 7,000, and the total aggregate value or investment at $3,000,000,000. The official figures do give some interesting data with reference to the municipal enterprises of the larger cities of the country, which are presented in the following table:—

Municipal Enterprises in the United States in 247 Cities of 30,000 Population and Over

Kind of utility	Number of plants	Value	Outstanding indebtedness	Outlays
Waterworks	206[1] (Out of 6,900)	$1,745,245,581[1]	$ 679,975,768[2]	$116,665,610[3]
Electric light, power and gas enterprises	28[1] (Out of 2,581)	137,910,383[1]	77,988,320[2]	18,568,854[3]
Markets	31[1]	43,592,143[1]	13,830,211[2]	3,925,537[3]
Street railways	16[4]	68,894,398[4]	37,881,600[4]	..
Ferries, bridges, harbours, ice plants and farms[5] (not segregated)	108[5]	684,144,698[1]	351,597,829[2]	62,313,364[3]
Total	247	$2,677,787,203[6]	$1,131,587,455[7]	$201,473,365

[1]U.S. Census, *Financial Statistics of Cities*, pp. 398 *seq.* (1925); [2]*ibid.* p. 430; [3]*ibid.* p. 366; [4]U.S. Census, Electric Railways, pp. 236–239 (1922); [5]Census lumps all these under heading "All other" as previously explained; [6]this includes $60,920,633, given in the report as value of "municipal service enterprises" not included in items in this table; [7]this includes $8,195,317 given in report as indebtedness of "municipal service enterprises" not included in this table.

The table on next page shows the "revenues, receipts," expenditures or "government cost payments for expenses" and net earnings or "excess of receipts over expenditures" of public service enterprises carried on by 247 of the largest cities in the United States.

Revenues, Expenditures and Net Earnings of Public Service Enterprises in 247 of the Largest Municipalities in the United States

Kind of utility	Revenues [1]	Expenditures "cost payments"	Excess of receipts over expenditures [4]
Waterworks	$157,898,606	$ 76,251,133 [2]	$81,647,473
Electric light and power	31,178,574	20,671,789 [2]	10,506,785
Street railways	35,745,013	27,880,868 [2]	7,864,145
Sewers and sewage disposal	..	19,855,414 [3]	−19,855,414
Garbage disposal	..	39,832,778 [3]	−39,832,778
Docks and wharves	13,505,453	5,888,516 [2]	7,616,937
Gas plants	7,143,504	4,363,785 [2]	2,779,719
Markets	3,451,849	1,964,520 [2]	1,487,329
Street construction, maintenance and lighting	118,606,532	133,214,039 [3]	−14,607,507
Cemeteries and crematories	1,926,541	2,443,950 [2]	− 517,409
Subways for pipes and wires	494,284	63,360 [2]	430,924
Scales	70,334	80,801 [2]	− 10,467
Ferries, toll bridges, harbours, lands, ice plants and farms	5,577,421	5,969,217 [2]	− 391,796
Public convenience stations	..	823,827 [3]	− 823,827
Halls	..	1,024,600 [2]	− 1,024,600
Total	$375,598,111	$340,328,597	$35,269,514

[1] All of the figures in the column on revenues are from the U.S. Census report, *Financial Statistics of Cities*, pp. 246, 230; [2] *ibid.* p. 342; [3] *ibid.* p. 286; [4] this column and totals our own.

Municipal Waterworks.—By far the most extensive field of "municipal trading" in the United States is that of public waterworks. The figures given above give only a very partial view of the situation. They cover only 247 out of nearly 7,000 municipalities that own and operate water-supply systems. The American Water Works Association estimates that over 90% of the urban population in the United States is served by public plants. We give below a table showing the financial operations of the four largest municipal water-supply systems:—

*Four Largest Water Systems**

	New York	Chicago	Philadelphia	Detroit
Value	$415,021,347	$91,908,955	$75,659,319	$45,362,806
Liabilities	196,000,000†	8,209,969	38,486,672	19,286,114
Revenues	20,281,284	10,162,361	6,835,521	5,323,295
Expenses	7,318,712	5,434,060	2,660,715	1,607,835
Gross surplus	12,962,572	4,728,301	4,174,806	3,715,460

*Compiled from U.S. Census report, *Financial Statistics of Cities*, pp. 246, 342, 398, 420; †Cornelius Sheehan, "Municipal Waterworks of New York," in *Public Ownership*, p. 39 *seq.* (March, 1926).

Municipal Light and Power Plants.—There are 2,581 municipally-owned light and power plants in the United States. The majority of these are in the smaller cities, towns and villages, but a number of the larger cities have very successful projects. Cleveland, O., was one of the first of the larger cities to establish a municipal plant, and has the distinction of being the first and only city to offer a maximum rate for domestic service of 3 cents per kilowatt hour. Los Angeles now has the largest of the municipal systems, with Seattle following closely. Tacoma has a complete monopoly of the power business. The table at the foot of the preceding column shows the financial operations of these four largest municipal plants.

Financial Operations of the Four Largest Municipal Electric Light and Power Plants in the United States

	Los Angeles*	Cleveland†	Seattle‡	Tacoma¶
Total assets	$64,104,668	$13,359,974	$40,963,740	$16,205,766
Liabilities	..	7,388,000	31,971,658	8,640,902
Revenues	12,658,994	3,377,132	37,142,955	1,758,202
Expenditures	6,504,885	1,690,637	17,504,057	561,268
Gross income before interest and depreciation	6,154,108	1,687,494	19,638,898	1,217,651
Interest and depreciation	2,895,620	365,970	11,472,845	623,315
Net income	3,258,488	1,320,524	8,166,052	594,336

*Audit by Price, Waterhouse and Co. (Los Angeles, 1927); †resumé of the 1927 reports of the Cleveland Lighting Plant, by F. W. Ballard; ‡*Annual Report*, Dept. of Lighting (Seattle, Dec. 1927); ¶Llewellyn Evans, superintendent, Light Division, Tacoma, Wash.

Street Railways.—As compared to England, there are but few municipally-owned street railways in the United States—only 16 in all. However, the city of San Francisco has had a long and quite satisfactory experience with its municipal railways; Seattle is working out its problems gradually; and Detroit now owns and operates the largest publicly-owned system in America, if not in the world. The following table will show the financial operations of the three largest municipal systems:—

The Three Largest Municipal Railway Systems in the United States

	Detroit*	San Francisco†	Seattle‡
Assets	$60,612,707	$11,080,168	$14,285,763
Liabilities	60,567,462	4,018,724	14,823,326
Revenues	23,787,435	3,466,715	5,758,291
Expense	18,535,903	2,879,905	5,491,770
Net income before capital charges	5,251,531	586,810	266,520
Interest and depreciation	1,897,178	415,130	168,073
Net income	2,805,361	171,679	156,590

**Financial Statement*, Detroit Street Railways (Aug. 31, 1928); †*Financial Report*, Municipal Railways of San Francisco (June 30, 1927); ‡Seattle Municipal Street Railways' *Annual Report* (Dec. 31, 1927).

(C. D. T.)

MUNICIPIUM, the term applied primarily to a *status*, a certain relation between individuals or communities and the Roman state (Lat. *munus*, a duty or privilege); subsequently to a community standing in such a relation to Rome.

Early History.—The status had its origin in the conferment of citizenship upon Tusculum in 381 B.C., and was widely extended in the settlement made by Rome at the close of the Latin War in 338 B.C. (*see* ROME: *History*). Italian towns were then divided into three classes: (1) *Coloniae civium Romanorum*, the members of which had all the rights of citizenship; (2) *municipia*, which received partial citizenship; (3) *foederatae civitates*, separate from Rome, and in relations with her separately arranged for each state by treaty (*foedus*). The *municipia* stood in very different degrees of dependence on Rome. Some, such as Fundi, enjoyed a local self-government only limited in the matter of jurisdiction; others, such as Anagnia, were governed directly from Rome. But all had certain features in common. Their citizens were called upon to pay the same dues and perform the same service in the legions as full Roman citizens, but had not the right of voting in the Comitia (*ius suffragii*) or of holding Roman magistracies (*ius honorum*). Jurisdiction was entrusted in every *municipium* to *praefecti iuri dicundo* sent out from Rome to represent the praetor urbanus. *Municipium* must therefore have been more a burden than a privilege. But after the Second Punic War, when Rome had become the chief power in the Mediterranean, we can trace a tendency among the Italian cities to regard citizenship of this great state as a privilege and to claim complete citizenship as a reward of their services in helping to build up the Roman power. During the 2nd century B.C. the *ius suffragii* and *ius honorum* were conferred upon numerous *municipia*. They can have exercised their public rights but seldom, owing to their distance from Rome.

Later Republic and Empire.—The result of the social war (*see* ROME: *History*) was the establishment of a new uniform municipality throughout Italy. By the Lex Iulia of 90 B.C. and the Lex Plautia Papiria of 89 B.C., every town in Italy which made application in due form received the complete citizenship. The term *municipium* was no longer confined to a particular class of Italian towns but included all urban communities of Roman citizens in Italy. The organization of a municipal system, which should regulate the governments of all these towns on a uniform

basis and define their relation to the Roman government, was probably the work of Sulla. Julius Caesar extended the sphere of the system by his enfranchisement of Cisalpine Gaul and the inclusion of all the towns of that region in the category of *municipia.* Augustus and his successors granted to existing towns in the provinces either the full citizenship or a partial *civitas* known as the *ius Latii,* and the distinction survived for some time in the provinces between *coloniae, municipia iuris Romani,* and *municipia iuris Latini.* But the uniform administration gradually adopted in all three classes rendered the distinction unimportant, and the general term *municipium* is used of all alike.

Internal Constitution.—Of the internal life of the *municipia* very little is known before the Empire, when a series of municipal laws gives us a detailed knowledge of the constitution imposed on the *municipia,* and a host of private inscriptions gives particulars of their social life.

The municipal constitution of the 1st century is based upon a type common to Greece and Rome from earliest times. The government of each town consists of magistrates, senate, and assembly, and is independent of the Roman government except in cases of higher civil jurisdiction, which come under the cognizance of the praetor urbanus at Rome (*see* PRAETOR). Each community is bound to perform certain services to the Imperial government, such as the contribution of men and horses for military service, the maintenance of the imperial post, and the entertainment of Roman officials or billeting of soldiers. The citizens were of two classes: (1) *cives,* whether by birth, naturalization, or emancipation, (2) *incolae,* who enjoyed a partial citizenship based on domicile for a certain period. Both classes were liable to civic burdens, but the *incolae* had a limited right of voting. The citizens were grouped in tribes or *curiae,* and accordingly the *comitia* sometimes bore the name of *tributa,* sometimes that of *comitia curiata.* The theoretical powers of these *comitia* were extensive, but the growing influence of the municipal senates gradually made popular election a mere form.

Social Organisation Under the Empire.—The *municipia* of the empire may be treated under three heads: (1) as centres of local self-government, (2) as religious centres, (3) as industrial centres. (1) The chief feature of the local government is the activity of the authorities in improving the conditions of life in the town. Provision was made out of the public funds for feeding the poor and providing corn which could be bought by ordinary citizens at a moderate price. In Pliny's time there existed in many towns schools controlled by the municipal authorities. Pliny promoted another kind of school at Como, where the leading townspeople subscribed for the maintenance of the school and the control remained in the hands of the subscribers. Physicians seem to have been maintained at the public expense. The water-supply was provided out of the municipal budget and controlled by magistrates. To enable it to bear the expense involved in all these undertakings, the local treasury was assisted by benefactions from individual citizens; but direct taxation was hardly ever resorted to. The treasury was filled out of the proceeds of the landed possessions of the community, especially mines and quarries, and out of import and export duties.

(2) The chief feature in the religious life of the towns was the position they occupied as centres for the cult of the emperor. Caesar-worship developed spontaneously in many provincial towns during the reign of Augustus, and was fostered by him and his successors as a means of promoting a strong loyalty to Rome and the emperor, which was one of the firmest supports of the latter's power.

(3) The development of this free industrial class is the chief feature of the *municipia* considered as centres of industry and handicraft. The rise of the equestrian order had to some extent modified the old Roman principle that commerce was beneath the dignity of the governing class; but the aristocratic notion survived in Rome that industry and handicrafts were fitted only for slaves. In the provincial towns, however, this idea rapidly disappeared, and even in Italy the inscriptions give evidence of the existence of a flourishing free industrial class. The members of this class show a strong tendency to bind themselves together in gilds (*collegia, sodalitates*). These societies were viewed with suspicion by the emperors as politically dangerous; but in spite of opposition the gilds in the provincial towns grew and flourished. The ostensible objects of such *collegia* were the worship of some god and provision for the funerary rites of their members.

The policy of encouraging the independence and civic patriotism of the towns was superseded in the 3rd and 4th centuries A.D. by a deliberate effort to use the towns as instruments of the imperial government, under the control of representatives of the emperor in the provinces. This policy was accompanied by a decay of civic feeling and municipal enterprise, which showed itself in the unwillingness of the townsmen to become candidates for local magistracies. Popular control of the towns was ceasing to be a reality by the end of the 1st century. Two centuries later local government was a mere form.

MUNISING (mū′nĭ-sĭng), a city of the Upper Peninsula of Michigan, U.S.A., on the south shore of Lake Superior; the county seat of Alger county. It is served by the Lake Superior and Ishpeming railroad. The population was 5,037 in 1920 (88% native white) and was 3,956 in 1930 by the Federal census. It has lumber, saw, paper, stave, shingle and veneer mills, and is a summer resort of many and varied attractions. The city is built around a semi-circular bay, protected by wooded headlands, and faces Grand island, a private game preserve, kept in primaeval beauty. Munising was founded in 1897 and incorporated as a city in 1913. It has a commission form of government.

MUNITIONS, MINISTRY OF. The Ministry of Munitions of the United Kingdom was created by act of parliament in May 1915 on the formation of the first Coalition Government.

The events which preceded its formation belong to the political history of that period, but, in effect, the creation of the Ministry resulted from the fact that the early months of the World War had shown that former methods of obtaining army supplies from a limited number of firms were inadequate to meet the needs of an army of unprecedented size and whose requirements were far beyond any previously contemplated, even for so large a force.

Its first obvious task was to make good the serious shortage revealed of guns and gun ammunition, but events moved so rapidly that during the formulation, in concert with the War Office, of the first detailed programme of requirements the demands became expanded beyond those first contemplated even in that programme. From that time onwards programme succeeded programme, each larger than its predecessor, in order to keep pace with the sustained bombardments at the front and with the introduction of new apparatus and methods of war.

With regard to the supplies that entered into the first programme, the subsequent increases specially affected the number and weight of guns and of their ammunition, as well as the numbers of machine guns; but the first of many successive programmes of trench warfare munitions soon followed, and the trench warfare department came to be responsible for the provision not only of grenades, bombs and mortars, but of steel helmets, chemicals and a great variety of special devices.

In the year 1916 the first considerable programmes of tanks and of aeroplanes were added, and the manufacture of agricultural implements, railway material and other supplies became the duty of the Ministry about the same time. In the end the Ministry became responsible for the complete mobilization of the whole of the British metal, engineering and heavy chemical trades, as well as of many related industries, and its powers were added to accordingly in successive acts of parliament.

The Plan of Operations.—The plan of the Ministry's operations was worked out during the summer of 1915, and, although it underwent enlargements and adjustments as new tasks were assumed, it remained unaltered in essentials. An understanding of these methods may be gained by reference to the procedures found to be necessary in the first year of the Ministry's activity.

It was necessary to enlist the aid, on some organized plan, of

the whole of the engineering and allied industries. There was a universal willingness to help, but in order to make that help available the widespread supply of designs and models, gauges and precise specifications was a first essential. This work involved the co-operation of many skilled trades, such as jewellers, scientific instrument makers, and others who were not obviously allied to munitions manufacture. Next, the variety in the equipment and capacity of the workshops, both in men and machinery, necessitated the improvisation of an elaborate machinery of association whereby it could be arranged that each should make such parts as they were suited for. These circumstances led the Ministry to become responsible for the supply of materials or parts, to claim priority of execution and to supply or move machinery or labour. In these cases, therefore, as well as where the firms were already suited to munitions manufacture, a class of "controlled establishments" was created, wherein the powers of the Ministry in regard to manufacture, materials and labour conditions were paramount. The number of these controlled establishments was constantly being added to as the work increased.

In order, locally, to marshal the help so freely available, a district, or "area organization" was set up under the superintendence in each area of a "munitions committee." These committees were usually staffed by experienced men in the locality, and they arranged, particularly, for the mobilisation and assistance of firms that had not previously been concerned with this type of work. The district offices of the Ministry also became the headquarters of its own officers who had direct responsibility for manufacture, inspection, materials and labour supply, costs and other duties.

Apart from the widespread assistance secured by the foregoing measures, the volume of contracts arranged directly by the ministry increased very rapidly as works extensions and the concentration of manufacture enabled many firms to undertake greater orders. The execution of the first programme, however, made it evident that the requirements would exceed all that could be provided by all such methods, and a number of "national factories," under the direct ownership of the Ministry, were provided. Some of these factories were of vast capacity, and they came to furnish an increasing proportion of the output. The national factories varied considerably in type; some were under the direct management of the local munitions committees, and were chiefly named after the towns in which they were situated, but these factories were not often large; others, sometimes of great size, for guns, machine guns, trench warfare and chemical supplies, for tanks or for aeroplanes, were erected by the Ministry but managed on an agency basis by experienced firms; others, and finally, the largest factories, were directly owned by the Ministry itself and managed by men appointed by it. The great explosive factories at Gretna, Queensferry and elsewhere, most of the filling factories, many special trench warfare and chemical factories, as well as some larger gun and shell factories, belonged to this group.

The widespread activities of the Ministry necessarily led to the institution of many novel methods of working and extensions of State activity, and a review of some of them is required for an understanding of the scope of the gigantic enterprise.

Intelligence and Improved Methods.—A central department was charged with the duty of transmuting into terms of machinery, materials and labour requirements the successive programmes supplied by the War Office. As a corollary of this work it was necessary, for example, to take the census of existing machinery in order to ascertain the new machinery requirements, and a special executive department was made responsible for the supply of all the machine tools and machinery shown to be required. Similar relations existed between the intelligence department and the other executive supply departments.

In the course of time the collection and analysis of progress reports, in comparison with the time-programme that had been worked out, led to the provision of "weekly reports" in such a form that the minister and the chief officers could readily keep in touch with events. In order also to facilitate the united exploration of deficiencies and difficulties a "fortnightly conference" was held of the minister and the chief heads of the departments; and the chief of the intelligence services was responsible for supplying the minister with a synopsis and criticism of the progress reports for that purpose.

The pooling of information as to progress and methods enabled the Ministry to have knowledge of the relative efficiency of different firms and processes and to use the knowledge thus obtained in promoting improvements. There was in consequence a rapid advance in many industrial methods.

Allied in aim to the intelligence service a valuable system sprang up in the executive departments, whereby there were regular conferences with works managers as to the value and results of different processes, and the recommendations were made available directly to the different firms as well as through the district officers of the Ministry.

On parallel lines a munitions inventions department was set up to receive and examine the numberless suggestions that were forthcoming from the humblest workers to trained experts, and many of the most fruitful new processes of the war period were obtained in this way. There was, of course, much that was useless in the mass of the material submitted to the different scientific and expert committees, but some thousands of suggestions were approved and ultimately adopted through the agency of this department.

Costs and Cost Accounting.—Owing to the fact that the requirements often involved the total producing capacity of the country competitive tenders were inapplicable, and the Ministry came to base prices upon an examination of the costs of production in typical cases after making adequate allowances for other charges and profits. The different national and co-operative factories afforded excellent facilities for these investigations although many of the more enterprising firms readily co-operated. The powers of the Ministry in this respect were added to in the first Munitions of War Amendment Act, but, after a short time, the powers to investigate costs compulsorily were not widely exercised. For the most part, prices became based upon an examination of the costs as found by the Ministry and by the different firms, although an independent special examination was often undertaken by the Ministry with the concurrence of the firms before a final agreement was arrived at. The first and most dramatic result of the use of these powers occurred in Feb. 1916 after it had been found that, making generous allowance for repayment of factory costs, many types of shell cases were being obtained at a little more than half former contract prices in the national factories and elsewhere. The prices for the principal shell cases were reduced as follows:

Shell Cases	*Previous Price*	*Reduced Price*
18 pounders	20s. to 23s.	12s.6d.
4·5″	47s. to 65s.	34s.
60 pounders	60s. to 82s.4d.	52s.6d.
6″	80s. to 90s.	70s.6d.
8″	240s.	157s.6d.
9·2″	262s. to 305s.	227s.6d.

As a part of the agreement entered into when these reductions were obtained, future prices became subject to periodic adjustment on the basis of the costs of materials and labour-rates over which the firms themselves had little control. The reductions in prices, as compared with earlier contracts, were also materially assisted by the great size of the contracts that were entered into, as well as by the economies that were subsequently secured, in the reduction in the amounts used of costly materials, or in the substitution for them of less costly ones. Nevertheless the savings effected by the examination and control of costs were of a prodigious character. The first cut in shell prices resulted in a saving of £400,000 a week on the 1916 gun ammunition programme, if the prices had been the same as those of 1915. Wages rose steadily throughout the war, but the economies effected in other directions made further reductions in the level of shell prices possible, notwithstanding the additional labour rates.

Supply of Materials, Priority and Allocation.—The first programme, when resolved into material requirements, showed that, in some cases, all, or more than all, of the available supplies would be needed. The scarcity also was leading to soaring prices, and in some instances the Ministry had to protect itself against

cornering. The result was that in successive "orders" the Ministry made itself the nominal holder of supplies as well as responsible for overseas purchases and shipments. The existing machineries of importation and distribution were used so far as possible and the different firms acted as agents on an agreed basis. In this way stability of price was secured and control over distribution. Apart, however, from the demands of the Ministry and other war departments, it was necessary to satisfy, so far as possible, the requirements of a multitude of private industries that were ministering to the essential needs of the community. For these reasons an increasingly elaborate system of priority and allocation came to be established, and the scarcity of the later years of the war became so acute that the priority organization became subject to a special cabinet committee. This cabinet tribunal, or its officers, was responsible for the adjudication of the conflicting claims of the different war departments on the one side, and of private industries on the other, but each war ministry was responsible for the allocation within itself of its own supplies. In order to secure an orderly presentation of the needs of private industry the Ministry of Munitions inaugurated a system, during 1916, whereby the industries were grouped, in order to present their requirements collectively, and, later on, these industrial organizations were mainly responsible for the administration of their own priorities and allocations.

The ever-tightening grip of the Ministry upon many materials affected the life of the nation in numberless intimate and, seemingly, indirect ways, and became itself responsible for the Ministry having to undertake the provision of some supplies of a non-munitions character. For example, the explosives programme so completely absorbed the output of gas plants, coke ovens and the chemical trade, that the Ministry had to become responsible for the supply of fertilizers to the agricultural industry. The demands for glycerine necessitated a pooling of all the industries dealing with oils and fats, and of their raw materials, with the result that the Ministry was compelled to regulate and assume responsibility for the supplies of cattle-cake and other products. Similarly the requirements for alcohol involved control of the whole distilling industry, and indirectly of the supply of yeast for bread-making.

Economy of Materials and Increased Production.—The restriction of overseas supplies that accompanied the submarine campaign of 1917 was mitigated to some extent by a great development in the economy of metals and in the improvement of salvage and scrap collection and utilization.

The successes of the materials economy department were dependent upon the initiation and conduct of research and experiment on an extensive scale and by the embodiment of their results in the modifications of design, as well as in minimizing the waste in many manufacturing methods. In a similar way the work of salvage and the collection and utilization of scrap from works was entrusted to special departments, and a number of factories were set up to convert or re-form the supplied materials. On the other hand the scarcity of some materials greatly stimulated home production where the necessary ores were obtainable and the Ministry was responsible for many extensions of steel works, recovery plants, chemical works, mining operations and so on. With regard to the non-ferrous metals the guidance and inspiration of this work was under the superintendence of a mineral resources development department.

Labour.—Just as the supply of materials involved the Ministry in many unforseen undertakings, so did the supply of labour, only in this case the difficulties were much greater owing to the intimate human interests that were involved. When the Ministry was established the demands of the fighting services for men had already begun to affect, not only the volume of available labour, but its quality, because so many highly-skilled craftsmen had already joined the colours. This double scarcity of volume and quality was the determining cause of the devices that came to be adopted.

Prior to the establishment of the Ministry, an agreement had been entered into with the trades unions of the engineering and allied trades (the "Treasury agreement"), an important ingredient of which was that future modifications of conditions of employment should not be accompanied by a reduction of rates paid for piece-work, and a pledge was given for the post-war restitution of pre-war conditions. (A similar pledge accompanied subsequent agreements.) The arrangement as to piece-rates, although just in itself, was the cause of much subsequent difficulty, because, as a result of training new labour and of the growing scarcity of skilled men, it became more and more necessary to remove skilled men from repetition work and use them for the more expert processes, which, by their nature, could only be paid by time rates. The consequence was that skilled men often found themselves receiving less pay than the unskilled workers introduced in the process of "dilution" whom they themselves had often trained for the work.

In order to assist the Ministry with the vexed questions that arose daily a joint committee (the "munitions labour supply committee"), of representative employers and trades unionists was set up and rendered invaluable service. This committee marked the beginning of a system of joint consultative bodies that worked both centrally and in the different districts and shops, in helping to deal with the multitudes of points that arose as to classification, wages, work conditions, hours and the rest.

Various devices were adopted to promote the augmentation of labour supplies. The War Munition volunteers was a body consisting of skilled men who were prepared to go wherever required, and they were often used in starting new factories or workshops, as well as in helping to speed up supplies that were urgently required.

The Army Reserve Munition workers was another body that came into being later on, and consisted of men who, owing to their skill, or for other reasons, had been brought back from the colours, or were not fit to rejoin them, and who were used somewhat similarly to the war munition workers.

Dilution of Labour.—But by far the greatest augmentation of labour was obtained by training men and women who were drawn from all manner of other occupations. The technical schools, colleges and universities were participants in the training schemes, but the greatest schools for training of the less expert crafts were in the works themselves. This process of "dilution" was signally successful. Its introduction and conduct were naturally attended by innumerable difficulties, and it is probably not too much to say that it could not have been successfully carried out except by the goodwill of the workmen and employers' representatives throughout the country. In one form or another dilution was responsible for the serious strikes that took place in the Clyde area, at Barrow and elsewhere, and these disturbances led to the creation of a special body of dilution commissioners who were set apart to superintend the introduction of new workers and to adjust disputes.

The breach with old industrial methods, and the utilization of vast numbers of new workers, especially of women workers, compelled the Ministry to take powers to regulate hours, wages and conditions of employment generally. This first introduction of women on a great scale into what had hitherto been regarded as the sphere of men's work, as well as other devices adopted at that time, are clearly destined to have an enduring social importance. A body of experts was set aside to study the conditions affecting the health and industrial capacity of munition workers (the "health of munition workers committee"). The work of this committee was sometimes of a striking, if of transitory importance, as in the elimination of T.N.T. poisoning in the explosive factories, but their inquiries into physique, into the effect of hours, posture, food supplies and methods, upon health and industrial output, are of permanent value. This work led to the establishment of the industrial fatigue research board, which is now attached to the national council of medical research under the Privy Council. Concurrently a close study of industrial welfare developed, and one branch of it was concerned with the provision of canteens in the different works and factories; but in many ways it has led to modifications in the conduct and standards of employment.

In order to safeguard essential labour from indiscriminate enlistment, the Ministry was made responsible for the issue of

exemption badges to skilled workers, and, later on, was required to issue badges on behalf of other war departments. The accompanying, but more difficult, work of de-badging that arose as the demands of the army for men became more urgent, was attached to the Ministry, and some serious industrial disputes arose over questions of exemption, or of alleged, improper recruitment, notably the disputes in Sheffield and in Lancashire, but, for the most part, such disputes, through the agency of the different local consultative committees, were capable of ready adjustment.

The Output of Munitions.—A brief summary will suffice to indicate, in terms of output, the results of this progressive mobilization of the resources of the nation in machinery, materials, science and invention, as well as in men and women so far as they were available.

The manufacture of explosives of different kinds at the commencement of the Ministry amounted to about 400 tons per week, and subsequently it exceeded 7,000 tons. The undertaking involved the unified direction of the chemical industries, gas works, distilleries, oils and fats trades and many allied industries. The filling of the shells, bombs, etc., involved the creation of vast filling factories, of assembly stations and transport arrangements, so that the weekly tonnage of filled ammunition sent across the English Channel came to exceed 53,000 tons per week.

During the progress of the war, the proportion of shells of the heavier natures was constantly increased, but the rise in the numbers of shells delivered as "completed rounds" is indicated in the following table:—

	Completed rounds per week
June 1915	200,000
June 1916	1,000,000
March 1917	2,000,000

The increase in the output of guns and machine guns was on similar lines, except that the number of machine guns per unit increased even more greatly towards the end of the war than that of guns. The trench warfare department became responsible for an increased volume of supplies, entirely comparable to that of shells, together with the materials for chemical warfare, both for offensive and defensive purposes. A committee of experts from the Royal Society and other learned bodies acted jointly for the Ministry and the War Office in this branch of supply, of which the character could only be described as increasingly ghastly as the war proceeded.

The provision of tanks in the first instance arose out of the work of a band of experts on mechanical warfare that had been set up by Winston Churchill at the Admiralty. Subsequently this organization was transferred to the Ministry of Munitions, which became responsible for experimentation with and for the supply of tanks. The supply of aircraft devolved from the air board upon the Ministry towards the end of 1916, and in this respect the Ministry acted as the supply department to the Ministry of Air, as it did in other respects for the War Office. Here, as in other cases, the elimination of a needless multiplicity of type and the standardization of production, together with scientific research, was attended with signal success.

The Ministers of Munitions.—The successive ministers were:—D. Lloyd George (from the commencement to June 1916), E. Montagu (June to Dec. 1916), Christopher Addison (under-secretary from commencement; minister Dec. 1916 to July 1917), Winston Churchill (from July 1917 to the end of the war).

Cole, "Trade Unionism and Munitions" and "Workshop Organization" (both 1923) in *Economic and Social History of the Great War, British Series;* Christopher Addison, *Politics from Within* (1924); D. Carnegie, *History of Munitions Supply in Canada* (1925).

(C. A.)

MUNKAČEVO, a town of Ruthenia, Czechoslovakia, situated on the left bank of the Latorica where it leaves the East Beskid highlands. Traditionally believed to be near the point where the Magyar entered the plain, the old fort on a hill in the vicinity has played an important part in Hungarian history as a defence and later as a prison. The town acts as a market and centre of contact for the hill and plain peoples and has several distilleries, breweries and small tobacco and flour-milling interests. Pop. (1923), 20,865, including 4,936 Ruthenians, 4,864 Magyars and 8,394 Jews.

MUNKACSY, MICHAEL VON (1844–1900), Hungarian painter, whose real name was MICHAEL (Miska) LEO LIEB, was born at Munkács, Hungary, on Feb. 20, 1844. He was apprenticed to a carpenter in 1855, but shortly afterwards made the acquaintance of the painters Fischer and Szamossy, whom he accompanied to Arad in 1858. About the end of 1867 he was working at Düsseldorf, where he painted (1868–69) "The Last Day of a Condemned Prisoner," exhibited in the Paris Salon in 1870. He had already paid a short visit to Paris in 1867, but in 1872 he settled there permanently. Munkacsy's other chief pictures are "Milton dictating *Paradise Lost* to his Daughters" (Paris Exhibition, 1878), "Christ before Pilate" (1881), "Golgotha" (1883), "The Death of Mozart" (1884), "Arpad, chief of the Magyars, taking possession of Hungary," exhibited at the Salon in 1893, and "Ecce Homo." He died on April 30, 1900, at Endenich, near Bonn.

See F. Walther Ilges, "M. von Munkacsy," *Künstler Monographien* (1899); C. Sedelmeyer, *Christ before Pilate* (1886).

MÜNNICH, BURKHARD CHRISTOPH, COUNT (1683–1767), Russian soldier and statesman, was born at Neuenhuntorf, in Oldenburg, in 1683, and was in the French, Hesse-Darmstadt and the Saxon services before, and with the rank of general-in-chief and the title of count, he joined the army of Peter II. of Russia. In 1732 he became field-marshal and president of the council of war. In 1734 he took Danzig, and with 1736 began the Turkish campaigns which made Münnich's reputation as a soldier. Working along the shores of the Black Sea from the Crimea, he took Ochakov in 1737, and in 1739 won the battle of Stavutschina, and took Khotin (or Choczim), and established himself firmly in Moldavia. Marshal Münnich now entered on political rivalry with Biron, duke of Courland. During the revolution of 1741 he was condemned to death, reprieved, and sent to Siberia, where he remained until 1762, when he was released. Catherine II. employed the old field-marshal as director-general of the Baltic ports. He died in 1767. As a statesman he is regarded as the founder of Russian Philhellenism.

He wrote an *Ébauche pour donner une idée de la forme de l'empire de Russie* (Leipzig, 1774), and voluminous diaries, of value for the history of the period, have appeared in various publications—Herrmann, *Beiträge zur Geschichte des russischen Reichs* (Leipzig, 1843). *See* Hempel, *Leben Münnichs* (Bremen, 1742); Halem, *Geschichte des F. M. Grafen Münnich* (Oldenburg, 1803; 2nd ed., 1838); Kostomarov, *Feldmarschall Münnich* (*Russische Geschichte in Biographien,* v. 2).

MUNRO, HUGH ANDREW JOHNSTONE (1819–1885), British scholar, was born at Elgin on Oct. 19, 1819, and died at Rome on March 30, 1885. He was educated at Shrewsbury and Trinity college, Cambridge, and was professor of Latin at Cambridge. His main editions are: Lucretius, his greatest work (text, 1 vol., 1860; text, commentary and translation, 2 vols., 1864); *Aetna* (1867); Horace (1868); *Criticisms and Elucidations of Catullus* (1878).

See *Memoir* by J. D. Duff, prefixed to a re-issue of the trans. of Lucretius in "Bohn's Classical Library" (1908).

MUNRO, MONRO or **MONROE, ROBERT** (d. *c.* 1680), Scots general. He served in the Scottish rebellion against Charles I., and in 1644 was appointed to command the parliamentary forces in Ireland. For disobedience to orders he was superseded by Monk in 1648. He was in part the original of Dugald Dalgetty in Sir Walter Scott's *Legend of Montrose.*

See J. T. Gilbert, *Contemporary History of Affairs in Ireland 1641–1652* (3 vols., Dublin, 1879–80).

MUNSEY, FRANK ANDREW (1854–1925), American publisher and newspaper proprietor, was born at Mercer, Me., on Aug. 21, 1854. Educated in public schools, he began business in a country store, and became manager of the Western Union Telegraph office in Augusta, Maine. In 1882 he went to New York city and in the face of great obstacles established the *Golden Argosy,* a magazine for children, later changing this to the *Argosy,* a magazine for adult readers. In 1889 he founded *Munsey's Week-*

ly, replaced two years later by *Munsey's Magazine*, the first monthly of its class to sell for 10 cents. He also founded the *All-Story Weekly* (1904) and the *Railroad Man's Magazine* (1906), and published various other magazines. In 1891 he purchased the New York *Star*, changing its name to the *Daily Continent* and making it a pioneer attempt to give the news in tabloid form. Among his outstanding newspaper purchases were the *Baltimore News* (1908), the *New York Press* (1912) and the *New York Sun*, both morning and evening issues (1916). He merged the *Press* in the *Sun*. In 1920 he bought from the executors of James Gordon Bennett's estate the New York *Evening Telegram* and the *New York Herald*, together with its Paris issue. He combined the *Herald* and the morning *Sun* as *The Sun and the New York Herald*, but in Oct. 1920, changed the name to the *New York Herald*, at the same time continuing the evening paper as the *Sun*. He died in New York city Dec. 22, 1925. By his will, after providing for relatives, he left the residue of his estate, estimated at $40,000,000, to the Metropolitan Museum of Art, New York. His financial success was due to unremitting labour and great shrewdness. He was the author of several books for boys.

Villard in *Some Newspapers and Newspaper Men* (1926). Some personal material is available in Munsey's introduction to *A Munsey-Hopkins Genealogy* (1920) and *The Story of the Founding and Development of the Munsey Publishing House* (1907).

MÜNSTER, SEBASTIAN (1489–1552), German geographer, mathematician and Hebraist, was born at Ingelheim in the Palatinate. He entered the Franciscan order, but adopted Lutheranism about 1529, and was appointed court preacher at Heidelberg. From 1536 he taught at Basle, where he published his *Cosmographia universalis* in 1544, and where he died of the plague on May 23, 1552. He was the first German to edit the Hebrew Bible (2 vols., fol., Basle, 1534–35). His most important work was his *Cosmographia*, which also appeared in German as a *Beschreibung aller Länder*, the first detailed, scientific and popular description of the world in German. In this Münster was assisted by more than 120 collaborators. The most valued edition of the *Cosmographia* or *Beschreibung* is that of 1550, especially prized for its portraits and its city and costume pictures. Besides the works mentioned above we may notice Münster's *Germaniae descriptio* of 1530, his *Novus orbis* of 1532, his *Mappa Europae* of 1536, his *Rhaetia* of 1538, his editions of Solinus, Mela and Ptolemy in 1538–40; his *Horologiographia* (1531) on dialling (*see* DIAL), his *Organum uranicum* of 1536 on the planetary motions, and his *Rudimenta mathematica* of 1551.

See V. Hantzsch, *Sebastian Münster* (1898), in vol. xviii. of the *Publications of the Royal Society of Sciences of Saxony* (*Historical-Philological Section*).

MUNSTER, a town in the department of Haut-Rhin, France, 16 m. from Colmar by rail, and at the foot of the Vosges mountains at the junction of two arms of the Fecht. Pop. (1926) 3,742. Its principal industries are spinning, weaving, bleaching and cheese-making. The town owes its origin to a Benedictine abbey, which was founded in the 7th century, and at one time it was a free city of the empire. The *hôtel de ville* is 16th century, and part of the abbot's palace remains. The town was much bombarded by the French during the war of 1914–18.

MÜNSTER, a town of Germany, capital of the province of Westphalia, lies in a sandy plain on the Dortmund-Ems canal, at the junction of several railways, 107 m. S.W. of Bremen on the line to Cologne. Pop. (1925) 105,889. Münster is first mentioned about the year 800, when Charlemagne made it the residence of Ludger, bishop of the Saxons. Owing to its distance from any available river or important highway, the growth of the settlement round the *monasterium* was slow, and it was not until after 1186 that it received a charter, the name Münster having supplanted the original name of Mimegardevoord about a century earlier. During the 13th and 14th centuries the town was one of the most prominent members of the Hanseatic League. At the time of the Reformation, the armed intervention of the bishop suppressed all divergence from the older faith. The authority of the bishops, who usually resided at Ahans, has been limited, but in 1661 the bishop built a citadel, and deprived the citizens of many privileges. The bishopric of Münster, embracing about 2,500 sq.m., contained about 350,000 inhabitants, and its bishops were princes of the empire. The bishopric was secularized in 1803.

The town preserves its mediaeval character, especially in the "Prinzipal-Markt" and other squares, with their gabled houses and arcades. The fortifications were dismantled during the 18th century. The cathedral was rebuilt in the 13th and 14th centuries, and combines Romanesque and Gothic forms; its chapter-house is specially fine. The Gothic church of St. Lambert (14th century) was largely rebuilt after 1868; on its tower hang three iron cages in which the bodies of John of Leiden and two of his followers were exposed in 1536. The church of St. Ludger, erected in the Romanesque style about 1170, was extended in the Gothic style about 200 years later. The church of St. Maurice, founded about 1070, was rebuilt during the 19th century, and the Gothic church of Our Lady dates from the 14th century.

Other noteworthy buildings are the town-hall, a Gothic building of the 14th century, and the Stadtkeller, which contains a collection of early German paintings. The room in the town-hall called the Friedens Saal, in which the peace of Westphalia was signed in Oct. 1648, contains portraits of many ambassadors and princes who were present at the ceremony. The Schloss, built in 1767, was formerly the residence of bishops of Münster. The private houses are admirable examples of German domestic architecture in the 16th, 17th and 18th centuries. The University of Münster, founded after the Seven Years' War and closed at the beginning of the 19th century, was reopened as an academy in 1818, and again attained the rank of a university in 1902. Münster is the seat of a Roman Catholic bishop and is a garrison town. Industries include weaving, dyeing, brewing and printing, and the manufacture of furniture, pianos, chocolates, surgical instruments, ropes, soap, cement and machines.

MUNSTER (*Mumha*) was one of the traditional five provinces or "Fifths" of Ireland which appear about A.D. 300, its capital being Cashel and its dynasty bearing the name "Eoghanachta," or descendants of Eoghan Mór (*floruit c.* A.D. 270). From these sprang the MacCarthys of Desmond (Des Mumha) or south Munster, while from a kindred stock came the Dalcassian kings of Thomond or north Munster (*Tuadh-Mumha*). Under Brian Boru (940–1014) the latter attained and kept the throne of Cashel. The Norman Conquest led to the O'Briens being reduced to the modern county Clare and the MacCarthys to west Cork and south Kerry. Munster was shired into Cork, Limerick, Kerry, Tipperary, Waterford and Thomond (Clare). The real sovereignty of Munster, however, passed to the Fitzgeralds, who from 1329 held the earldom of Desmond, and the Butlers, who similarly held the earldom of Ormond, both palatinates under the Crown. The Lord Deputy Sidney in 1576 added Clare (*q.v.*) to Connaught, but it reverted to Munster at the Restoration. Sidney also made Munster a presidency and in 1583, the Desmond rebellion was suppressed.

MÜNSTERBERG, HUGO (1863–1916), German-American psychologist and philosopher, was born in Danzig on June 1, 1863, and died in his lecture-room at Radcliffe college on Dec. 16, 1916. He was educated at Danzig *Gymnasium*, at Geneva and at the universities of Leipzig (Ph.D., 1885) and Heidelberg (M.D., 1887). At Freiburg, where he began his teaching, he had a psychological laboratory in his house. Through the influence of William James he went to Harvard university in charge of the psychological laboratory in 1892–95. Later, he was chairman of the department of philosophy. He was Harvard exchange professor at the University of Berlin in 1910–11. He did much to promote the new science, not only through his college teaching, but through his contacts with industrial firms. His numerous writings include *Beiträge zur experimentellen Psychologie* (Freiburg, 1889–92), *Grundzüge der Psychologie* (Leipzig, 1900), *Die Amerikaner* (1903) and *Grundzüge der Psychotechnik* (1914). In English he published text-books and lighter essays, including *American Traits* (1901); *Psychology and the Teacher* (1909); *American Problems* (1910); *Psychology and Industrial Efficiency*

(1913); and *Psychology: General and Applied* (1914), as well as his books on the great conflict *The War and America* (1914) and *The Peace and America* (1915). His system of philosophy, the consummation of his previous effort, he presented, however, in both German and English as *Philosophie der Werte* (1908) and *The Eternal Values* (1909).

MUNTJAC, a small deer, of the genus *Cervulus*, only found in south-eastern Asia (*see* DEER). They have long bodies and short limbs and necks. The antlers of the buck are short, simple and supported on very long processes of the frontal bones, the front edges of which are continued downwards as ridges on to the face. The upper canine teeth of the male form long tusks, loosely implanted in their sockets. The presence of both tusks and antlers in the same species is very unusual. Solitary in habit, the muntjacs haunt hilly forests, living in the dense thickets and only emerging at dawn and dusk to graze. They are remarkable for the facility with which they creep through tangled undergrowth. Their alarm cry is a short, shrill bark. The Indian muntjac is *C. muntjac;* other species inhabit Tibet, Tenasserim, and south-eastern China.

MUNTZ METAL, a variety of brass, invented by G. F. Muntz in 1832, is also known as "yellow metal" because the large zinc content gives it a very yellow colour. The alloy is composed of 60% copper and 40% zinc. It can be forged, and is employed for machine parts, exposed to corrosion. (*See* ALLOYS; BRASS.)

MÜNZER, THOMAS (*c.* 1489–1525), German anabaptist, was born at Stolberg in the Harz, and educated at Leipzig and Frankfort, graduating in theology. In 1520 he became a preacher at the church of St. Mary, Zwickau, and his rude eloquence, together with his attacks on the monks, soon raised him to influence. Aided by Nicholas Storch, he formed a society on principles akin to those of the Taborites, and claimed that he was under the direct influence of the Holy Spirit. Driven out of Zwickau he went to Prague, where he won numerous adherents, but his violent language brought about his expulsion from this city also. At Easter 1523 Münzer came to Allstedt and began to preach at the church of St. John. His preaching and his denunciation of Luther's teaching soon produced an uproar in Allstedt, and he left the town for Mühlhausen, where Heinrich Pfeiffer was already preaching doctrines similar to his own. The union of Münzer and Pfeiffer caused a disturbance in this city and both were expelled. Münzer went to Nuremberg, where he issued a writing against Luther. He now denounced established governments, and advocated community of goods. After a tour in south Germany he returned to Mühlhausen, overthrew the governing body of the city, and established a communistic theocracy. The Peasants' War had already broken out in various parts of Germany; and Münzer collected a body of men, and established his camp at Frankenhausen. On May 15, 1525, the peasants were dispersed by Philip, landgrave of Hesse. Münzer was executed on the 27th at Mühlhausen.

His *Aussgetrückte Emplössung des falschen Glaubens* was ed. by R. Jordan (Mühlhausen, 1901), and a life of Münzer, *Die Histori von Thome Müntzer des Anfengers der döringischen Uffrur*, has been attributed to Philip Melanchthon (Hagenau, 1525). *See* O. Merx, *Thomas Münzer und Heinrich Pfeiffer* (Göttingen, 1889); J. Zimmermann, *Thomas Münzer* (1925). The Saxon Historical Commission had (1928) in hand an edition of his letters.

MURAD I., surnamed Khudavendighiar (1319–1389), Ottoman sultan, was the son of Orkhan and the Greek princess Nilofer, and succeeded his father in 1359. He was the first Turkish monarch to obtain a definite footing in Europe and his main object throughout his career was to extend the European dominions of Turkey. The revolts of the prince of Caramania interfered with this plan, and the trouble continued until the decisive battle of Konia (1387), when the power of the prince was broken. The state of Europe facilitated Murad's projects; the feudal system was at its last gasp, and the Balkan states were divided by jealousies. The capture of Adrianople and other conquests led to a coalition under Hungary against Murad, but his able lieutenant Lalashahin, the first *beylerbey* of Rumelia defeated the allies at the battle of Maritsa in 1363. In 1366 the king of Servia was defeated at Samakov and forced to pay tribute. Kustendil, Philippopolis and Nish fell into the hands of the Turks; a renewal of the war in 1381 led to the capture of Sofia two years later. Europe was now aroused; Lazar, king of Servia, formed an alliance with the Albanians, the Hungarians and the Moldavians against the Turks.

Murad hastened back to Europe and met his enemies on the field of Kossovo (1389). Victory finally inclined to the side of the Turks. When it was complete, a Servian named Milosh Kabilovich penetrated to Murad's tent on pretence of communicating a secret and stabbed the conqueror. Murad was of independent character and remarkable intelligence. He was fond of pleasure and luxury, cruel and cunning. Long relegated to the command of a distant province in Asia, while his brother Suleiman occupied an enviable post in Europe, he became revengeful; thus he exercised great cruelty in the repression of the rebellion of his son Prince Sauji, the first instance of a sultan's son taking arms against his father. Murad transferred the Ottoman capital from Brusa to Adrianople. The feudal system of *timars* and *ziamets* and its extension to Europe were largely his work.

MURAD II. (1403–1451), Ottoman sultan, succeeded his father Mahommed I. in 1421. The attempt of his uncle Prince Mustafa to usurp the throne, supported as it was by the Greeks, gave trouble at the outset of his reign, and led to the unsuccessful siege of Constantinople in 1422. Murad maintained a long struggle against the Bosnians and Hungarians, in the course of which Turkey sustained many severe reverses through the valour of Janos Hunyadi. Accordingly in 1444 he concluded a treaty at Szegedin for ten years, by which he renounced all claim to Servia and recognized George Brancovich as its king. Shortly after this, being deeply affected by the death of his eldest son Prince Ala-ud-din, he abdicated in favour of Mahommed, his second son, then fourteen years of age. But the treacherous attack, in violation of treaty, by the Christian powers, imposing too hard a task on the inexperienced young sovereign, Murad returned from his retirement at Magnesia, crushed his faithless enemies at the battle of Varna (November 10, 1444), and again withdrew to Magnesia. A revolt of the janissaries induced him to return to power, and he spent the remaining six years of his life in warfare in Europe, defeating Hunyadi at Kossovo (October 17–19, 1448). He died at Adrianople in 1451.

MURAD III. (1546–1595), Ottoman sultan, was the eldest son of Selim II., and succeeded his father in 1574. His accession marks the definite beginning of the decline of the Ottoman power, which had only been maintained under Selim II. by the genius of the all-powerful grand vizier Mahommed Sokolli. For, though Sokolli remained in office until his assassination in October 1578, his authority was undermined by the harem influences, which with Murad III. were supreme. Of these the most powerful was that of the sultan's chief wife, named Safié (the pure), a beautiful Venetian of the noble family of Baffo, whose father had been governor of Corfu, and who had been captured as a child by Turkish corsairs and sold into the harem. This lady ruled over him to the last.

His one attempt at reform, the order forbidding the sale of intoxicants to the janissaries, broke down on the opposition of the soldiery. He was the first sultan to profit by the corrupt sale of offices. This corruption was fatally apparent in the army, the feudal basis of which was sapped by the confiscation of fiefs for the benefit of nominees of favourites of the harem, and by the intrusion, through the same influences of foreigners and rayahs into the corps of janissaries, of which the discipline became more and more relaxed and the temper increasingly turbulent. In view of this general demoralization not even the victorious outcome of the campaigns in Georgia, the Crimea, Daghestan, Yemen and Persia (1578–1590) could prevent the decay of the Ottoman power; indeed, by weakening the Mussulman states, they hastened the process, since they facilitated the advance of Russia to the Black Sea and the Caspian.

Murad, who had welcomed the Persian War as a good opportunity for ridding himself of the presence of the janissaries, whom he dreaded, had soon cause to fear their triumphant return. Incensed by the debasing of the coinage, which robbed them of part of their pay, they invaded the Divan clamouring for the heads of the sultan's favourite, the *beylerbey* of Rumélia, and of the *defterdar* (finance minister), which were thrown to them

(April 3, 1589). This was the first time that the janissaries had invaded the palace: a precedent to be too often followed. The outbreak of another European war in 1592 gave the sultan an opportunity of ridding himself of their presence. Murad died in 1595, leaving to his successor a legacy of war and anarchy.

It was under Murad III. that England's relations with the Porte began. Negotiations were opened in 1579 with Queen Elizabeth through certain British merchants; in 1580 the first capitulations with England were signed; in 1583 William Harebone, the first British ambassador to the Porte, arrived at Constantinople, and in 1593 commercial capitulations were signed with England. (*See* CAPITULATIONS.)

MURAD IV. (1611–1640), Ottoman sultan, was the son of Sultan Ahmed I., and succeeded his uncle Mustafa I. in 1623. For the first nine years of his reign his youth prevented him from taking more than an observer's part in affairs. But the lessons thus learnt were sufficiently striking to mould his whole character and policy. In 1631 the spahis of Asia Minor rose in revolt, in protest against the deposition of the grand vizier Khosrev; their representatives crowded to Constantinople, stoned the new grand vizier, Hafiz, in the court of the palace, and pursued the sultan himself into the inner apartments, clamouring for seventeen heads of his advisers and favourites, on penalty of his own deposition. Hafiz was surrendered, a voluntary martyr; other ministers were deposed; Mustafa Pasha, aga of the janissaries, was saved by his own troops. But Murad was now beginning to assert himself. Khosrev was executed in Asia Minor by his orders; a plot of the spahis to depose him was frustrated by the loyalty of Koes Mahommed, aga of the janissaries, and of the spahi Rum Mahommed (Mahommed the Greek); and on May 29, 1632, by a successful personal appeal to the loyalty of the janissaries, Murad crushed the rebels, whom he surrounded in the Hippodrome. At the age of twenty he found himself possessed of effective autocratic power.

His severity has remained legendary. Death was the penalty for the least offence, and no past services—as Koes Mahommed was to find to his cost—were admitted in extenuation. The use of tobacco, coffee, opium and wine were forbidden on pain of death; eighteen persons are said to have been put to death in a single day for infringing this rule. The tale of his victims is said to have exceeded 100,000.

Murad's great physical strength was maintained by constant physical exercises. He was also fond of hunting, and for this reason usually lived at Adrianople. He broke through the alleged tradition, bequeathed by Suleiman the Magnificent to his successors, that the sultan should not command the troops in person, and took command in the Persian war which led to the capture of Baghdad (1638) and the conclusion of an honourable peace (May 7, 1639). Early in 1640 he died, barely twenty-nine years of age. The cause of his death was acute gout brought on by excessive drinking. In spite of his drunkenness, however, Murad was a bigoted Sunni, and the main cause of his campaign against Persia was his desire to extirpate the Shia heresy. He amused his entourage by feats of strength, and by verses, some of which were published under the pseudonym of Muradi.

See, for details of the lives of the above, J. von Hammer-Purgstall, *Geschichte des osmanischen Reiches* (Pest, 1840), where further authorities are cited.

MURAD V. (1840–1904), Ottoman sultan, eldest son of Sultan Abd-ul-Mejid, was born on Sept. 21, 1840. On the accession of his uncle Abd-ul-Aziz, Prince Mahommed Murad Effendi—as he was then called—was deprived of all share in public affairs and imprisoned, owing to his opposition to the sultan's plan for altering the order of succession. On the deposition of Abd-ul-Aziz on May 30, 1876, Murad was haled from his prison by a mob of softas and soldiers of the "Young Turkey" party under Suleiman Pasha, and proclaimed "emperor by the grace of God and the will of the people."

Three months later, his health, undermined by his long confinement, gave way; and on Aug. 31, he was deposed to make room for his younger brother, Abd-ul-Hamid II. Confined in the Cheragan palace, he died on Aug. 29, 1904.

See Kératry, *Mourad V., prince, sultan, prisonnier d'état 1840–1876* (Paris, 1878); Djemaleddin Bey, *Sultan Murad V., the Turkish Dynasty Mystery, 1876–1895* (London, 1895).

MURAENA, name of an eel common in the Mediterranean, and sometimes applied to the whole genus. Some 90 species are known from tropical and sub-tropical seas, especially in rocky parts or on coral reefs. The skin is scaleless and smooth, in many species ornamented with varied and bright colours, so that they are frequently mistaken for snakes. The mouth is wide, the jaws strong and armed with formidable teeth, which enable the *Muraena* not only to seize its prey (which chiefly consists of other fishes) but also to inflict serious wounds on its enemies, including man.

Some of the tropical *Muraenas* exceed a length of 10ft., but most of the species attain to only half that length. *M. helena* of the Mediterranean was a great delicacy of the ancient Romans. Some are said to have thrown slaves into their fish-ponds to feed the *Muraenas*. This form ranges through the Indian Ocean and reaches Australia.

MURAL CROWN, in heraldry (*q.v.*), a crown taking the form of an embattled tower given to the man who first set up his standard in a captured city.

MURAL PAINTING concerns that branch of art which has for its object the covering or "dressing" of a building so that its purpose may be "sweetened" or intensified by the decoration. This decoration, therefore, must be considered from two points of view: fitness and adornment. Fitness prescribes the nature; adornment the aesthetic design of such paintings. Most buildings are structures composed, roughly speaking, of two elements: the space-bearing and the space-enclosing. The tentpole and the four posts, or columns, with their transverse beams, are the space-bearing parts of architecture; the walls, whether of canvas, like a tent's, of wood, lath and plaster, brick or stone, are the space-enclosing but not necessarily structural elements; nor are the roofing and the ceiling necessarily structural. The decorations of architecture, therefore, naturally fall into two categories —those which are applied to the structural parts and those which cover the enclosing parts. In good architecture, at all events, these differences are discernible so that one may say that the structural elements are decorated with ornament whilst the enclosing or mural parts are covered with some kind of "dressing," of which mural painting is, aesthetically, the most important, but to which must also be reckoned panelling, mosaic, tapestry, painted patterning and papering, and even stained glass, which after all is only a translucent wall.

Egypt.—Such painted architectural decoration appears to have found its earliest and certainly its most vital expression in Egypt. The Egyptians were, like all primitive races, symbolizers. The fitness of any given design would therefore be decided not merely by its natural derivation and consequent position, but also by its symbolic significance. They were thus the most logical mural decorators imaginable, for their ornament had its origin in nature, its position from its original place and its meaning from its associations with their religious belief. This also is true of the pictorial decoration of their walls. Aesthetic considerations were here as little dominant as in their ornament. Every discovery of Egyptian art points to the fact that they had very logical but also very simple notions of aesthetic composition, which was founded upon symmetry. This symmetry is an expression of the *natural* instinct for aesthetic order before it has become aware of more subtle modes of achieving balance.

Magnificent imitators of natural form as they were—at all events, at some periods of their six or seven thousand years of history—they never in their mural painting, as distinct from their sculpture, sacrificed clarity of meaning to beauty or truth of expression. Hence their custom of representing the human figure partly *en face*, partly in profile, so that one might see both legs and feet, both shoulders, arms and hands. To think of Egyptian mural decoration as an expression of aesthetic pleasure would therefore be manifestly wrong; what aesthetic pleasure might be derived was, if not an unconscious result, at all events no more than a means to an end. Indeed, Egyptian art appears to have been the source of all that kind of art which became eventually not

only conscious but self-conscious and, so to speak, self-sufficient.

What is true of Egyptian art is true to a great extent also of that of the neighbouring civilization of Mesopotamia comprising the Babylonian, or Chaldaean, the Assyrian and the Persian empires, and covering a period from 4000 to 333 B.C.

Greece.—The Greeks painted the structural features of their temples and even coloured their sculpture, but we know little about their painting except from their literature. This may be because it was not truly mural, but hung on the walls in wooden frames. Moreover, from their habit of personifying time, place and event, and the addition in script of the names of the persons represented, which we notice on their vases, we may judge that their method of composition was not aesthetic but ideological. The Parthenon shows a curious contradiction in aesthetic notions; for, whilst the tympana or gable-fields are decorated with figures that are roughly symmetrical in arrangement and follow the triangular shape of the architecture, they have no organic rhythm, they do not belong together. On the other hand, the sculptured frieze, with its rhythmical procession of horsemen, is the most magnificent decoration of that part of architecture imaginable, precisely because it has the two fundamentals, continuity and variety.

Rome.—Roman pictorial art, like sculpture, followed the Greek, but in mural decoration the Romans have invented a style peculiar to themselves. They are the inventors or, at all events, the exploiters of that form of painted ornamentation known as "grotesque," which had originally not the connotation of the bizarre with which it is invested now, but only indicated a stylized and decorative composition of human, animal and plant forms—especially used for the filling of long and narrow spaces such as that of pilasters. Typical of their domestic interior decoration is that found in Pompeii; it was mural painting in the fullest meaning of the word. The walls were made to resemble feigned architectural "scenes"; the wall, itself usually coloured (Pompeian) red, sometimes yellow or, more rarely, blue or green, was divided horizontally in three parts by means of a narrow frieze and dado, and, at intervals, vertically with devices of feigned architectural "prospects." The centres of the main fields of the walls were embellished either by a mural subject picture or by small isolated figures appearing as it were to be floating in space; the dado, often representing a niche or architectural recess, also contained little compositions of landscape or still life, whilst the frieze and margins of the wall might have fanciful embellishments of "grotesques," festoons or abstract pattern. The impression of Pompeian decoration is, with its incidents of gambolling "putti," doves and quaint attempts at *trompe-l'oeil,* is light and playful and reminds one in spirit at least of the decorations of the 18th century in France, the "Rococo." As regards the more ambitious subject paintings which formed part of the walls—such as the celebrated Aldobrandini-Wedding, now in the Vatican, dating from the 1st century A.D., which was discovered in 1606 and then created a sensation—it is clear that they are infinitely more modern in feeling than the art of the middle ages and the paintings before Raphael's time; but they are less "decorative," not only than mediaeval art but also than the paintings of Egypt, Crete or Assyria.

A more vital form of decoration which the Romans received by way of the Greeks from Asia and Egypt is mosaic. The well-known "Battle of Alexander" from the "House of the Faun" in Pompeii gives one some idea of the technical skill with which the mosaicist was able to translate into mosaic a picture designed originally in another medium; the original of this subject is supposed to have been a Greek painting. Mosaic, indeed—apart from its use as a floor covering—took the place of mural painting in Byzantine times.

The Near East.—A fresh development in mural painting took place when Islam came upon the scene and spread from Arabia east and west so far as India and Spain. The Arabs and the Jews kept alive the scientific and abstract philosophic culture of the Greeks which Christianity destroyed. They were the scientists, mathematicians and geometricians of their era; furthermore their religion forbade them the representation of natural forms. Out of these two conditions sprang the logical, intricate yet marvellously beautiful and consistent style of their decoration. Its beauty was formal and abstract; but it is against human nature to create or to be satisfied with pure aesthetics, that is to say, beauty without associative significance. They therefore extracted from their science the ingenious geometrical forms which characterize their ornament, whilst their picturesque script took the place of pictorial representation and so invested the decoration with meaning. The gold script on blue ground, the primary colours used to embellish the geometrical ornament, carved on stucco in relief, and their very original "stalactite" ceilings combined to give their mural decoration an effect of clear-cut yet romantic splendour not surpassed by any other style. The best-known specimen of Saracenic decoration is the Alhambra at Granada, dating from the middle of the 13th century, but magnificent earlier examples are in the mosques of Jerusalem, Damascus and Cairo. In the use of script, the Saracenic decorators were, perhaps, only rivalled in ingenuity by the Mayas of Central America who evolved a decorative effect with literary meaning from the square which appears to have been the unit, not only of their ideograms but of their architecture in general.

The Renaissance.—Mural painting fell into disuse as the highest form of mural decoration when mosaic took its place: but it may, perhaps, be doubted whether until the Renaissance it had ever taken the foremost place in decoration—sculpture being probably regarded as superior. When next we meet with the remains of wall paintings, during the 10th to 14th centuries—virtually the "Gothic" era—they are inferior in decorative value to that most wonderful of all decorative devices, stained glass (*q.v.*) and even to tapestry. (*See* TAPESTRY.) The painted chamber is, at all events, always one of less importance in a palace than the rooms decorated with arras and tapestry—an art which incidentally the Christian world owes to the preservative energy of the Saracens.

Mural painting owes its eminence as a fine art—that is to say, as distinct from pure decoration—to a movement towards a return from Byzantine formalism to nature. This movement in so far as it was religious is associated with St. Francis and in so far as it was artistic with Giotto. Giotto was a realist—his aims were naturalistic, *i.e.,* directed towards discovering means of greater verisimilitude. This is perhaps best proved by comparison of the paintings of the later upper chapel in Assisi with those of the earlier lower chapel. The latter obey the architecture to a far greater degree and have in consequence a much more decorative effect than those in the upper chapel which are mainly a series of story pictures. In Masaccio's paintings, Byzantine formalism is overcome; the *mise en scène* is more natural, but also the decorative value is not so pronounced.

In Fra Angelico's art we have a reaction; no progress is made in naturalism, but a truer sense of decorative values, within the area of each picture, is discernible. In the art of his pupil, Benozzo Gozzoli, however, we find a strongly pronounced decorative sense best seen in the so-called "Journey of the Magi" in the Riccardo palace in Florence. This is in the main due to Gozzoli's concentration upon forms and colours as such; they are to him all of equal interest whether they happen to belong to men or dogs, to trees or rocks—they are all considered in relation to the scheme as a whole. In spirit, therefore, if not in form, they are akin to the Flemish tapestries which reached their best period at about the same time, the latter part of the 15th century.

It is no exaggeration to say that decorative painting was, as a conscious aesthetic effect, misinterpreted by the great painters of the Renaissance. The interest in natural form, the discovery of Greek sculpture, and the very fact that the painters educated themselves from these sculptural models account for the fact that the solid qualities of the figure, the suggestion of the third dimension, became the preoccupation of these masters, who aimed at realism and, it may be added, were expected to do so. In Correggio's agreement for the frescoes in the Parma cathedral, dated Nov. 3, 1522, it was expressly stipulated: "That he shall engage to paint the choir, the arcades and arches with their mouldings and all the wall space in the chapel decorating these with given subjects which shall either be imitations of life or

MOSAICS AND FRESCOES

1. Interior of the Lower Church of St. Francis, at Assisi, Italy. Frescoes (*c.* 1300) in the vaulting above the high altar, representing the Mystic Marriage of St. Francis with Holy Poverty, Chastity, Obedience, and St. Francis in glory, are ascribed to Giotto or to one of his pupils
2. Façade of Orvieto Cathedral (begun in 1310), showing the use of mosaics for exterior wall decoration
3. Interior of the Basilica of St. Paul's Outside the Walls, Rome, founded in 386. The space above the triumphal arch is filled with a mosaic decoration executed under Galla Placidia; portraits in mosaic of all the popes from St. Peter to Benedict XV. form a frieze around the nave walls below the clerestorey windows
4. "The Rout of San Romano," one of a group of three frescoes painted by Paolo Uccello (15th century) for decoration of the Palazzo Medici, Florence. Now in the National Gallery, London
5. Interior of the Sistine Chapel of the Vatican, showing above the altar "The Last Judgment," by Michelangelo (1475–1564). The ceiling also is entirely covered with frescoes by Michelangelo, arranged in a symmetrical architectural grouping. The frescoes on the side walls are by Botticelli, Ghirlandaio, Perugino, Pinturicchio and other painters of the Renaissance
6. "The Crucifixion," by Tintoretto (Jacopo Robusti, 1518–94), in the Scuola di San Rocco, Venice

BY COURTESY OF (5) THE METROPOLITAN MUSEUM OF ART, NEW YORK; PHOTOGRAPHS (1, 3, 4) PUBLISHERS PHOTO SERVICE, (2) ANDERSON

MURAL PAINTINGS AND TAPESTRIES

1. "The Last Supper," by Andrea del Sarto (1519), Florentine, on the wall of the refectory in the Abbazia di San Salvi, near Rovezzano, Tuscany
2. "The School of Athens," by Raphael (Raffaello Sanzio, 1483–1520), in the Stanza della Signatura, the Vatican. The scene represents the triumph of Philosophy with Plato and Aristotle as the centre of a gathering of philosophers and scholars of all the ages
3. Sala del Maggior Consiglio, Doges Palace, Venice. The walls are decorated with large canvases by the brothers Tintoretto, and other 16th century painters. On the entrance wall is "Paradise," by Jacopo and Domenico Tintoretto. It is 72 by 22 ft., and is said to be the largest oil painting in the world
4. Gobelin tapestries used as wall decoration in the Palace of Versailles, France. In the 17th century such tapestries replaced mural paintings, but were designed in the manner of paintings, with borders imitating the carved and gilt frames of the period
5. Sketch for a ceiling painting by Tiepolo (1727–1804), Venetian

of bronze or marble, according as the place may demand. . . ."

It is for such reasons that all the famous masters of the Renaissance as, for example, Piero della Francesca, with his decorations in S. Francesco, Arezzo, Signorelli in the cathedral of Orvieto, Pinturicchio in the Appartamenti Borgia in the Vatican, Raphael in the Stanze there, Michelangelo in the Sistine chapel, must all be appreciated as painters, as creative artists, but not decorators pure and simple. Their object was to create an illusion of space which should destroy the architecture, not preserve it. This architecture-destroying aim is visible also in the work of one of their best masters, Correggio, though his earlier work, the decoration of the convent of S. Paolo in Parma, shows, especially in the ceiling of the dome, a better compromise, since by means of a trellis work of vine leaves from which are hung branches of fruit he preserves the structure of the architecture. If illusion-creating and architecture-destroying qualities are to be regarded as characteristic of mural decoration then Raphael, Michelangelo, Correggio, Tintoretto were great decorators and Tiepolo the last and perhaps greatest of them all.

How confused the ideas in this respect were may be judged from the fact that when in the 17th century tapestries (Gobelins) once more replaced mural paintings they were designed in imitation of oil paintings and bordered not by "verdures"—the flowered pattern of the earlier tapestries—but by imitations of the carved and gilt frames of the time.

The 18th Century.—What is probably the best period in European decoration is the French of the 18th century, in which a perfect consistency ran through every part of interior architecture and every piece of furniture, down to the smallest article—such as a snuffbox. Although painting was widely used for the decoration of almost every conceivable object, it is significant that wall paintings fell into comparative disfavour, mirrors being preferred as wall decorations. Boucher, however, is typical of such painted decoration as there was in France. It is also to be noted that serious easel picture painting had almost ceased; Chardin, the only serious painter of the age, was soon "despised and rejected." This attitude is also characteristic of the only complete English style of decoration, that of the brothers Adam. The great English portrait painters certainly furnished the walls with their portraits, but the decorative picture was hung over the mantelpiece and doors—often not even properly filling the space of the panel—or let into medallions in the ceiling where it soon blackened and became unsightly. Mention must, however, be made of the hand painted wallpaper, done in imitation of Chinese models, or even imported from China.

The 19th Century.—As a result of the industrial and political revolutions, decoration, and with it mural painting, disappeared as a natural expression of culture from civilization. Where there is not one dominating spirit such as that of the tribe, the village community, the church, the prince, the aristocracy, there the soil out of which the life of decoration grows becomes sterile and has to be artificially fed. This happened in European civilization during the 19th century. There was no class which demanded mural painting as an expression of its social significance, however laudably, if wrongly, artists like Haydon tried to press its need. Commercial manufacture took the place of the hand; the craft of decoration slipped into the offices of commercial contractors who employed "hands," no longer craftsmen with a tradition behind them.

Individual efforts at the resuscitation of mural decoration were made by German artists, notably Peter von Cornelius (1783–1867) who painted the Casa Bartholdy in Rome in 1811 and many others in Munich and Berlin, and his pupil Wilhelm von Kaulbach (1805–74), whose decorations in the Neues museum, painted in a kind of fresco, are his chefs-d'oeuvre.

Under German influence Lord Leighton painted his two lunettes in the Victoria and Albert museum, London, of which one, "the Arts of War," is a really admirable example of true mural painting, both in design and technique. Ford Madox Brown deserves mention in this connection on account of his wall paintings in the Manchester town hall, though they are more successful as story-telling pictures than as decoration.

To William Morris is mainly due the revival of the interest in interior decoration which has spread throughout the world, but, in his scheme, mural painting as such was not understood, he having rather Gothic stained glass, tapestries and textiles in mind for the purpose, and employing Burne-Jones to design the former. During this time Puvis de Chavannes made a noble attempt to create a new logic of mural painting which would exclude any tricks of illusion, but would preserve the sense of the wall. To that end he simplified his drawing, distributed his points of interest by the arrangement of his figures and bound the composition together by a landscape setting which fulfilled its function as a foil and background without "making a hole in the wall." The principal means by which he achieved the desired flatness was the restriction of his palette to a scheme of grey-blues and grey greens. One of his ablest successors is Maurice Denis who, acting on similar principles of simplification, added nevertheless more gaiety—rose pinks—to his palette.

Two great American painters, John Singer Sargent and Edwin Abbey, tried their hand also at mural painting, but the former was too much of a nature imitator, the latter too much of an illustrator to solve the problems satisfactorily. So with Albert Besnard of France.

Modern Decoration.—Modern conditions have prevented the traditional development of a true style in decoration.

All that such a decorator can hope to achieve in the circumstances is the creation of an aesthetic unity within such limits as the purpose of the building and the architectural setting of the space he is to cover with a painting will permit.

Fresco painting and its various methods, "in which carbonate of lime is formed and encloses the colours applied to the wet wall" (*see* Hamilton Jacks on *Mural Painting*), are laborious and unsuitable for damp climates. A more convenient medium is distemper or tempera painting, in which the colours are bound by egg, size or gum.

Yet another is the wax medium, not the old encaustic process, but one recently invented: it has the advantage of being as easily handled as oil colours and of producing a pleasing surface which is not so dull or "mat" as fresco nor so shiny as ordinary oil painting. There is, however, also a method of using oil as a vehicle without producing a shiny surface.

Whatever medium be employed, the principal thing is that the design should be conceived in the spirit of the architecture which the mural painting is to decorate, and by the term decorating is here meant not only an adornment envisaged but, for less ambitious schemes, a feeling of physical and mental comfort.

The next consideration is that the design as such should form a connected whole, so that the eye, passing from one wall to the next, should travel by pleasant successive stages. This means that if there are several paintings there must be a uniform scale to link them together, a uniformity that is not only in the scale of the design but also its colours. It may be better to paint, for example, a historical personage who is known to have worn a red cloak on that occasion in a grey one if grey will fit better into the general scheme, or to paint the trees blue or brown rather than green if that produces a better harmony. In short, a mural painting should be treated as if it were a page in a book of poetry and not as a chapter in a tome of history.

Having thus determined the general scheme and the details of composition, the artist makes a series of sketches trying out various ideas and possibilities of composition and ultimately deciding on those which best seem to fulfil the conditions imposed. He next makes the many necessary studies from life and ultimately draws, from memory rather than from the models, the cartoon, that is to say, the outlines of the design in the actual size of the painting. He then transfers the cartoon by tracing to the wall, or to the canvas, which latter should be fixed to the wall by "marouflage"—a kind of glue partly formed of the remains of brush washings. The wall or canvas is now ready for painting.

As a matter of aesthetic effect, it is well to remember that colours have a different carrying power, so that those parts of the wall which are in shade must be treated differently from those

which are in light, and the colours in any case so orchestrated that they, as it were, hold each other in the same plane; otherwise the painting will look restless or patchy like a faded Gobelin.

It is further necessary to distribute the interest of the design over the whole surface, otherwise the effect of decoration will be lost, and, in the most favourable circumstances, a purely pictorial interest result; for whilst easel pictures are a form of art in which concentration of interest within the frame is permissible and even desirable, mural paintings should have their interest so distributed that they fulfil their function, which is to decorate the larger architectural unit, like a pattern. For this reason, too, the decorator or his patrons should consider whether the architecture is of a kind that calls for mural paintings and would not perhaps be better served by ornamentation with colour of the architectural parts bearing the wallspaces to be covered with abstract pattern. The ceiling offers particular difficulties. If it must be painted otherwise than with simple colour or architectural ornament at all, it is best to treat it as lightly as possible so as not to give its representations of nature the appearance of physical weight, and moreover to see to it that its main design links up architecturally everywhere with the walls so as to give the figures or other features a visible means of support—as Correggio did in the S. Paolo or Tiepolo in the Escorial ceilings. The mural painter's task is now the more difficult as he has the distracting experience of many styles of different ages and climes before his eyes or in his mind. The tendency in England is towards a thin early Italian drawing and colouring, whilst on the Continent everywhere extravagance, either in subject or in treatment, down to perfect abstraction is in vogue. Every form of design is justifiable, provided it keeps within the spirit of the environing architecture and the purpose of the building. "Jazz" pattern in a church would be as unsuitable as "church" pattern in ball-, bath- or bed-room. (F. Bn.)

MURANO, an island in the Venetian lagoon about 1 m. N. of Venice. Pop. (1921) 5,131—in the 16th century about 30,000. It was a favourite resort of the Venetian nobility before they began to build their villas on the mainland; and in the 15th and 16th centuries its gardens were famous.

The town is built upon one broad main canal, where the tidal current runs with great force, and upon several smaller ones. The cathedral, SS. Maria e Donato, is a fine basilica, of the 9th–12th century. The pavement (of 1111) is richly inlaid, and the mosaics of the tribune are remarkable. The beautiful exterior of the tribune has been well restored. The church of St. Peter the Martyr contains a fine picture by Gentile Bellini and other works. Murano has from ancient times been celebrated for its glass manufactories. (*See* Glass.)

The island of Murano was first peopled by the inhabitants of Altinum. It originally enjoyed independence under the rule of its tribunes and judges, and was one of the 12 confederate islands of the lagoons. In the 12th century the doge, Vital Micheli II., incorporated Murano in Venice and attached it to the Sestiere of S. Croce, placing it under a Venetian podestà.

MURAT, JOACHIM (1767–1815), king of Naples, younger son of an innkeeper at La Bastide-Fortunière (Lot), was born on March 25, 1767. He studied canon law at Toulouse, but enlisted in a cavalry regiment, from which he was dismissed in 1790 for insubordination. Through the good offices of J. B. Cavaignac, he was enrolled in the New Constitutional Guard of Louis XVI.

In 1795 he met Napoleon Bonaparte, whom he assisted on the 13th Vendémiaire, and to whom he acted as first aide-de-camp in Italy. He distinguished himself in the campaign of 1796 and '97, became commandant at Rome in 1798 and in the same year accompanied Bonaparte to Egypt. At the battle of the Pyramids he led his first famous cavalry charge, and for his exploits in Syria was made general of division (Oct. 1799). Returning to France with Bonaparte, he led into the orangery of Saint Cloud the 60 grenadiers whose appearance broke up the Council of Five Hundred (18th Brumaire), and for his success was made commandant of the consular guard. On Jan. 20, 1800, he married Caroline Bonaparte, youngest sister of the first consul. He commanded the French cavalry at the battle of Marengo, was made governor of the Cisalpine Republic, and in 1801, he forced the Neapolitans to evacuate the Papal States and to accept the Treaty of Florence. As governor of Paris (1804) he appointed the commission by which the duc d'Enghien was tried and shot; in May he was made marshal of the empire; in Feb. 1805 he was made grand admiral, with the title of prince, and invested with the grand eagle of the Legion of Honour. For his prowess as commander of the Grand Army in the German campaign of 1805, Napoleon made him grand duke of Berg and Cleves (March 15, 1806). He subsequently commanded the cavalry at Jena, Eylau and Friedland, and in 1808 was made general-in-chief of the French armies in Spain. Though disappointed of the throne of Spain, he was made king of Naples on Aug. 1, in succession to Joseph Bonaparte.

King Joachim Napoleon, as he styled himself, entered Naples in September, and soon after wrested Capri from the British. At Naples he set up a sumptuous court, created a new nobility, nominated marshals, swept away the last relics of the effete feudal system, and effectively suppressed brigandage. From the first his relations with Napoleon were strained. The emperor upbraided him sarcastically for his "monkey tricks" (*singeries*); Murat ascribed to the deliberate ill-will of the French generals who served with him, and even to Napoleon, the failure of his attack on Sicily in 1810. A breach was averted by Napoleon's invitation to Murat to command the cavalry of the Grand Army in the Russian Campaign of 1812; but although Murat displayed his usual intrepidity in the disastrous retreat, his suspicions of Napoleon, and his wife, Caroline, led him to throw up his command and return to Naples in December. The battle of Leipzig found him again at Napoleon's side, but on Oct. 16, Metternich opened a separate negotiation with him, and feeling that on his acceptance of Austrian advances depended his chance of continuing a king, Murat agreed to withdraw his support from Napoleon if his throne were guaranteed by England and Austria. Having obtained the emperor's leave to return to Naples, he entered that city on Nov. 4, and immediately made overtures to the allies through the Austrian envoy. On Jan. 11, 1814, a treaty was signed by which Austria guaranteed to Murat the throne of Naples, and promised her good offices to secure the assent of the other Allies. Secret articles further stipulated that Austria would endeavour to secure the renunciation by Ferdinand of his rights to Naples, in return for an indemnity to hasten the conclusion of peace between Naples and Great Britain, and to augment the Neapolitan kingdom at the expense of the States of the Church.

Meanwhile Murat had formally broken with Napoleon and on Jan. 16, the French envoy left Naples. But he now became the cat's-paw of the Allies, who, with the exception of Austria, refused to recognize his title. At the opening of the Congress of Vienna, Talleyrand affected not to know "the man" who was referred to as "the King of Naples," and his attitude was representative of the other congressistes who wished for the restoration of the Bourbons. The tortuous diplomatic proceedings which ensued roused Murat's suspicions, and, breaking with Austria as he had formerly broken with Napoleon, he determined to secure his throne by proclaiming the cause of united Italy. Already popular with the Neapolitans, his chances of success were enhanced by the escape from Elba of Napoleon, with whom he had been corresponding, but as soon as he mobilized his troops, the Allies commissioned Austria to deal with him. Ferdinand IV. was to be restored to Naples, on promising a general amnesty and giving guarantees for a "reasonable" system of government. Meanwhile Murat's popularity in Naples had waned, and his troops were routed at Tolentino on May 2; Austrians advanced on Naples, Ferdinand IV. was restored, while Queen Caroline and her children

EXAMPLES OF MODERN MURAL PAINTING BY ENGLISH, FRENCH AND AMERICAN ARTISTS

1. "The Arts of War," one of two lunettes by Lord Leighton (Frederick Leighton, 1830–96). In the Victoria and Albert Museum
2. "Moses and the Tablets of the Law" by Gerald Moira, English, contemporary. In the Central Criminal Court, London
3. "The Golden Tree and the Achievement of the Grail" by Edwin Austin Abbey (1852–1911). The last panel of the series of the Holy Grail, a frieze decoration in the Boston Public Library
4. "Sylvie" by Jean Dupas, French, contemporary. In the salon of the S.S. "Ile de France"
5. "Astarte" by John Singer Sargent (1856–1925), American. One of the panels of the series The Pageant of Religion in the Boston Public Library
6. "Moloch" by John Singer Sargent. Another panel of the same series in the Boston Public Library
7. "L'Après-midi d'un Faune" by Louise Janin, American, contemporary

were deported to Trieste.

Murat himself escaped to France, where his offer of service was contemptuously refused by Napoleon. He hid for a while near Toulon, with a price upon his head, then, after Waterloo, refusing an asylum in England, he sailed for Corsica, where he was joined by a few rash spirits who urged him to attempt to recover his kingdom. Refusing Metternich's offer to allow him to join his wife at Trieste and to secure him a position and a pension, Murat sailed for Calabria on Sept. 28, with a flotilla of six vessels and about 250 men. Four of his ships were scattered by storm, one deserted him, and on Oct. 8, he landed at Pizzo with only 30 men. Captured almost immediately, he was imprisoned at Pizzo, and on Oct. 13 was court-martialled and shot.

He was the most dashing cavalry leader of the age. Rash, hot-tempered and brave, he was adored by the troops, who followed him against the most terrible odds. Napoleon lived to regret his refusal to accept his services during the Hundred Days, declaring that Murat's presence at Waterloo would have inspired the cavalry charges and might have changed defeat into victory.

By his wife Maria Annunciata Carolina, Murat had two sons. The elder, Napoleon Achille Murat (1801–1847), during his father's reign prince royal of the Two Sicilies, emigrated about 1821 to America, and settled near Tallahassee, Florida, where in 1826–1838 he was postmaster. In 1826 he married a great-niece of Washington. He published *Lettres d'un citoyen des États-Unis à un de ses amis d'Europe* (Paris, 1830); *Esquisse morale et politique des États-Unis* (*ibid.*, 1832); and *Exposition des principes du gouvernement républicain tel qu'il a été perfectionné en Amérique* (*ibid.*, 1833). He died in Florida, on April 15, 1847.

The second son, Napoleon Lucien Charles Murat (1803–1878), created prince of Ponte Corvo in 1813, lived with his mother in Austria after 1815, and in 1824 started to join his brother in America, but was shipwrecked on the coast of Spain and held for a while a prisoner. Arriving in 1825, two years later he married in Baltimore a rich American, Georgina Frazer (d. 1879); but her fortune was lost, and for some years his wife supported herself and him by keeping a girls' school. After several abortive attempts to return to France, the revolution of 1848 at last gave him his opportunity. He was elected a member of the Constituent Assembly and of the Legislative Assembly (1849), was minister plenipotentiary at Turin from October 1849 to March 1850, and after the *coup d'état* of Dec. 2, 1851, was made a member of the consultative commission. On the proclamation of the empire, he was recognized by Napoleon III. as a prince of the blood royal, with the title of Prince Murat. He died on April 10, 1878, leaving three sons and two daughters, (1) Joachim, Prince Murat (1834–1901) in 1854 married Maley Berthier, daughter of the Prince de Wagram, who bore him a son Joachim (b. 1856) who succeeded him as head of the family, and two daughters, of whom the younger, Anna (b. 1863), became the wife of the Austrian minister Count Goluchowski. (2) Achille (1847–1895) married Princess Dadian of Mingrelia. (3) Louis (b. 1851), married in 1873 to the widowed Princess Eudoxia Orbeliani (*née* Somov), was for a time orderly officer to Charles XV. of Sweden. (4) Caroline (b. 1832) married in 1850 Baron Charles de Chassiron and in 1872 John Garden (d. 1885). (5) Anna (b. 1841), married in 1865 Antoine de Noailles, duc de Mouchy.

MURATORI, LUDOVICO ANTONIO (1672–1750), Italian scholar, historian and antiquary, was born of poor parents at Vignola in the duchy of Modena on Oct. 21, 1672. Having taken minor orders in 1688, Muratori took his doctorate in law before 1694, was ordained priest in 1695, and appointed by Count Carlo Borromeo one of the doctors of the Ambrosian library at Milan. From manuscripts now placed under his charge he made a selection of materials for several volumes (*Anecdota*), which he published with notes. He returned to Modena in 1700, on the invitation of the duke, as keeper of the archives. The preparation of numerous valuable tracts on the history of Italy during the middle ages, and of dissertations and discussions on obscure points of historical and antiquarian interest, as well as the publication of his various philosophical, theological, legal, poetical and other works absorbed the greater part of his time. These brought him into communication with the most distinguished scholars of Italy, France and Germany. But they also exposed him in his later years to envy. His enemies spread abroad the rumour that the pope, Benedict XIV., had discovered in his writings passages savouring of heresy, even of atheism. Muratori appealed to the pope, and was assured of his protection. Muratori died on Jan. 23, 1750.

Muratori is rightly regarded as the "father of Italian history." This is due to his great collection, *Rerum italicarum scriptores*, to which he devoted about 15 years' work (28 vols., 1723–38). This was followed by a series of 75 dissertations on mediaeval Italy (*Antiquitates italicae medii aevi*, 6 vols., 1738–42). To these he added a *Novus thesaurus inscriptionum* (4 vols., 1739–43), which was of great importance in the development of epigraphy. He then set about a popular treatment of the historical sources he had published. These *Annali d'Italia* (1744–49) reached 12 volumes, but were imperfect and are of little value. In addition to this national enterprise (the *Scriptores* were published by the aid of the Società palatina of Milan) Muratori published *Anecdota ex ambrosianae bibliothecae codd.* (2 vols., Milan, 1697, 1698; Padua, 1713); *Anecdota graeca* (3 vols., Padua, 1709); *Antichita Estens* (2 vols., Modena, 1717); *Vita e rime di F. Petrarca* (1711), and *Vita ed opere di L. Castelvetro* (1727). In biblical scholarship Muratori is famous as the discoverer of the so-called *Muratorian Canon*, the name given to a fragment (85 lines) of early Christian literature, which he found in 1740, embedded in an 8th-century codex which forms a compendium of theological tracts followed by the five early Christian creeds. The document contains a list of the books of the New Testament, a similar list concerning the Old Testament having apparently preceded it. There is little doubt that it was composed in Rome, and we may date it about the year 190. It is the earliest document known which enumerates the books in order. It is interesting to notice the coincidence of the compiler's list with the evidence gained from Tertullian for Africa and from Irenaeus for Gaul and indirectly for Asia Minor.

Muratori's *Letters*, with a *Life* prefixed, were published by Lazzari (2 vols., Venice, 1783). His nephew, F. G. Muratori, also wrote a *Vita del celebre Ludov. Ant. Muratori* (Venice, 1756). *See* also A. G. Spinelli, "Bibliographia delle lettere e stampa di L. A. Muratori," in *Bolletino dell' instituto storico italiano* (1888), and Carducci's preface to the new *Scriptores*. The *Muratorian Canon* is given in full with a translation in H. M. Gwatkin's *Selections from Early Christian Writers*. It is also published as No. 1 of H. Lietzmann's *Kleine Texte für theologische Vorlesungen* (Bonn, 1902). *See* also *Journal of Theological Studies*, viii. 537.

MURAVIEV, MICHAEL NIKOLAIEVICH, Count (1845–1900), Russian statesman, was born on April 19, 1845. He was the son of General Count Nicholas Muraviev (governor of Grodno), and grandson of the Count Michael Muraviev, who became notorious for his drastic measures in stamping out the Polish insurrection of 1863 in the Lithuanian provinces. He was educated at a secondary school at Poltava, and was for a short time at Heidelberg university. In 1864 he entered the chancellery of the minister for foreign affairs at St. Petersburg, and was soon afterwards attached to the Russian legation at Stuttgart. He served in various European capitals, and finally became minister at Copenhagen. In Denmark he was brought much into contact with the imperial family, and on the death of Prince Lobánov in 1897 he was appointed by the Tsar Nicholas II. to be his minister of foreign affairs. As regards Crete, Count Muraviev's policy was vacillating; in China his hands were forced by Germany's action at Kiaochow. But he acted with singular *légèreté* with regard at

all events to his assurances to Great Britain respecting the leases of Port Arthur and Talienwan from China; he told the British ambassador that these would be "open ports," and afterwards essentially modified this pledge. When the Tsar Nicholas inaugurated the Peace Conference at the Hague, Count Muraviev extricated his country from a situation of some embarrassment. When Russian agents in Manchuria and at Peking connived at the agitation which culminated in the Boxer rising of 1900, the relations of the responsible foreign minister with the tsar became strained. Muraviev died suddenly on June 21, 1900.

MURCHISON, SIR RODERICK IMPEY (1792–1871), British geologist, was born at Tarradale, Scotland, on Feb. 19, 1792. Educated at Durham and the military college, Great Marlow, he landed (1808) with Wellesley in Galicia, and was present at the actions of Roriça and Vimiera. Under Sir John Moore he took part in the retreat to Corunna.

In 1818 he sold his paternal property in Ross-shire and settled in England, where he took to field sports. He soon became one of the greatest fox-hunters in the midland counties. Sir Humphry Davy persuaded him to attend lectures at the Royal Institution. He joined the Geological Society of London, and, with the help of W. H. Fitton, prepared his first scientific paper, read to the society in 1825. In three years he had explored large parts of England and Scotland, had obtained materials for three important memoirs, as well as for two more written in conjunction with Sedgwick, and had risen to be a prominent member of the Geological Society and one of its two secretaries. He then explored with Lyell the volcanic region of Auvergne, parts of southern France, northern Italy, Tirol and Switzerland. Later, with Sedgwick as his companion, he attacked the difficult problem of the geological structure of the Alps, and their joint paper giving the results of their study is one of the classics in the literature of Alpine geology.

In 1831, at the suggestion of Buckland, he visited the Welsh border, to discover whether the greywacke rocks underlying the Old Red Sandstone could be grouped into a definite order of succession, as the Secondary rocks of England had been made to tell their story by William Smith. For several years he worked in that region. The result was the establishment of the Silurian system—under which were grouped for the first time a remarkable series of formations, each containing distinctive organic remains older than and very different from those of the other rocks of England. These researches, together with descriptions of the coal-fields and overlying formations in south Wales and the English border counties, were embodied in *The Silurian System* (1839), illustrated with map, sections, pictorial views and plates of fossils. As years passed on the types of existence brought to light by him from the rocks of the border counties of England and Wales were ascertained to belong to a geological period of which there are recognizable traces in almost all parts of the globe. Thus the term "Silurian," derived from the name of the old British tribe Silures, soon passed into the international vocabulary.

The establishment of the Silurian system was followed by that of the Devonian system, an investigation in which, aided by the palaeontological assistance of W. Lonsdale, Sedgwick and Murchison were fellow-labourers, both in the south-west of England and in the Rhineland. Murchison then projected an important geological campaign in Russia. He was accompanied by P. E. P. de Verneuil (1805–73) and Count A. F. M. L. A. von Keyserling (1815–91), in conjunction with whom he produced a magnificent work on *Russia and the Ural Mountains* (1845). In 1846 he was knighted, and in the same year he presided over the meeting of the British Association at Southampton. During the later years of his life a large part of his time was devoted to the affairs of the Royal Geographical Society, of which he was in 1830 one of the founders, and he was president 1843–45, 1851–53, 1856–59 and 1862–71. He was interested in the work of Livingstone. He devoted his last year to the Scottish Highlands, where he believed, erroneously, he had succeeded in showing that the vast masses of crystalline schists, then supposed to be part of what used to be termed the Primitive formations, were really not older than the Silurian period, for that underneath them lay beds of limestone and quartzite containing Lower Silurian (Cambrian) fossils.

In 1855 Murchison was appointed director-general of the geological survey and director of the Royal School of Mines and the Museum of Practical Geology in Jermyn street, London. He prepared successive editions of his work *Siluria* (1854, 5th ed., 1872), which was meant to present the main features of the original *Silurian System* together with a digest of subsequent discoveries, particularly of those which showed the extension of the Silurian classification into other countries. In 1863 he was made a K.C.B., and three years later was raised to the dignity of a baronet. The learned societies of his own country bestowed their highest rewards upon him, and he received many foreign honours.

Murchison founded a chair of geology and mineralogy in the University of Edinburgh. He died on Oct. 22, 1871. Under his will there was established the Murchison medal and geological fund to be awarded annually by the Geological Society.

See Sir A. Geikie, *Life of Sir Roderick I. Murchison* (1875).

MURCIA, a maritime province of south-eastern Spain. Pop. (1920), 638,639; area, 4,453 sq.m. It was the first Spanish possession of the Carthaginians, and the Romans included it in Hispania Tarraconensis. Under the Moors the province was known as Todmír, which included, according to Edrisi, the cities Murcia, Orihuela, Cartagena, Lorca, Mula and Chinchilla. The kingdom of Murcia, which came into independent existence after the fall of Omayyads (*see* CALIPHATE) included the present Albacete as well as Murcia. It became subject to the crown of Castile in the 13th century. Until 1833 the province of Murcia also included Albacete.

The extent of coast is about 75 m. and the mountains reach their highest point (5,150 ft.) on the Sierra de Espuña, between the Mula and Sangonera valleys. They are rich in iron, copper, argentiferous lead, alum, sulphur and saltpetre. Mineral springs occur at Mula, Archena (hot sulphur), and Alhama (hot chalybeate). The climate is hot and dry, and agriculture is largely dependent on irrigation, which, where practicable, has been carried on since the time of the Moors. Wheat, barley, maize, hemp, oil and wine (the latter somewhat rough in quality) are produced; fruit, especially the orange, is abundant along the course of the Segura; mulberries for sericulture are extensively grown around the capital; and the number of bees kept is exceptionally large. Esparto grass is gathered on the sandy tracts. Large quantities of lead and esparto, as well as of zinc, iron and copper ores, and sulphur, are exported. The province is traversed by a railway which connects Murcia with Albacete and Valencia; from Alcantarilla there is a branch to Lorca and Baza. The chief towns are Murcia, the capital, Cartagena, Lorca, La Unión, Mazarrón, Yecla, Jumilla, Águilas, Caravaca, Totana, Cieza, Mula, Moratalla and Cehegín.

MURCIA, the capital of the Spanish province of Murcia; on the river Segura, 25 m. W. of the Mediterranean sea. Pop. (1920), 141,175. Murcia was a town before the Punic Wars, but its name then, and under Roman rule, is not known, though some have tried to identify it with the Roman Vergilia. To the Moors it was known as Medinat Mursiya. After the fall of the caliphate of Cordova it passed successively under the rule of Almería, Toledo and Seville. In 1172 it was taken by the Almohades, and from 1223 to 1243 it became the capital of an independent kingdom. After its recapture by the Christians, Moorish princes continued to rule in name over a mixed population, but in 1269 a rising against the suzerain, Alphonso the Wise, led to the final incorporation of Murcia (which then included the present province of Albacete) into the kingdom of Castile.

Murcia has been an episcopal see since 1291. It is built nearly in the centre of a low-lying fertile plain, known as the *huerta* or garden of Murcia, which includes the valleys of the Segura and its right-hand tributary the Sangonera, and is surrounded by mountains. Despite the proximity of the sea, the climate is subject to great variations, the summer heat being severe, while frosts are common in winter. The streets are broad, straight and planted with avenues of trees, but the Calle de Platería and Calle de la Trapería are lined with old-fashioned balconied houses, and so

narrow that wheeled traffic is not easy. The cathedral, dating from 1388–1467, is in the main late Gothic, but a Renaissance dome and a tower 480 ft. high were added in 1521, while a Corinthian façade was erected in the 18th century. Since 1875 the industrial importance of Murcia has steadily increased. Mulberries (for silkworms), oranges and other fruits are largely cultivated in the *huerta,* and the silk industry, which dates from the period of Moorish rule, is still carried on. Manufactures of woollen, linen and cotton goods, of saltpetre, flour, leather and hats, have been established.

MURDER, in law, the unlawful killing of a person with malice aforethought (*see* HOMICIDE). It is defined by Lord Coke in his *Institutes* as "where a person of sound memory and discretion unlawfully killeth any reasonable creature in being and under the King's Peace. with malice aforethought, either express or implied."

MURDOCK, WILLIAM (1754–1839), British inventor, was born near Auchinleck, Ayrshire, on Aug. 21, 1754. In 1777 he entered the employment of Boulton & Watt in the Soho works at Birmingham, and about two years afterwards he was sent to Cornwall to superintend the fitting of Watt's engines. At Redruth he is said to have carried a series of experiments in the distillation of coal so far that in 1792 he was able to light his cottage and offices with gas. After his return to Birmingham about 1799, he made such progress in the discovery of practical methods for making, storing and purifying gas that in 1802 a portion of the exterior of the Soho factory was lighted with it in celebration of the peace of Amiens, and in the following year it was brought into use for the interior. Murdock was also the inventor of important improvements in the steam-engine. He was the first to devise an oscillating engine, of which he made a model about 1784; in 1786 he was busy—somewhat to the annoyance of both Boulton and Watt—with a steam carriage or road locomotive; and in 1799 he invented the long D slide valve. He is also believed to have been the real deviser of the sun and planet motion patented by Watt in 1781. In addition his ingenuity was directed to the utilization of compressed air, and in 1803 he constructed a steam gun. He retired from business in 1830, and died at Soho on Nov. 15, 1839.

MURE, SIR WILLIAM (1594–1657), Scottish writer, born at Rowallan, Ayrshire, was a member of the Scottish parliament in 1643, and took part in the English campaign of 1644, and was wounded at Marston moor. He wrote *Dido and Aeneas;* a translation (1628) of Boyd of Trochrig's Latin *Hecatombe Christiana; The True Crucifixe for True Catholikes* (1629); a paraphrase of the Psalms; the *Historie and Descent of the House of Rowallane; A Counter-buff to Lysimachus Nicanor; The Cry of Blood and of a Broken Covenant* (1650); besides much miscellaneous verse.

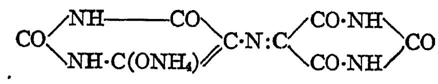
A complete edition of his works was edited by William Tough for the Scottish Text Society (2 vols., 1898). Mure's *Lute-Book,* a musical document of considerable interest, is preserved in the Laing collection of mss. in the library of the University of Edinburgh.

MURETUS, the Latinized name of MARC ANTOINE MURET (1526–1585), French humanist, who was born at Muret near Limoges on April 12, 1526. At the age of eighteen he attracted the notice of the elder Scaliger and soon made his name as a teacher of Latin. Some time before 1552 he delivered a course of lectures in the college of Cardinal Lemoine at Paris, which was largely attended, Henry II. and his queen being among his hearers. His success made him many enemies, and he was thrown into prison on a disgraceful charge, but released by the intervention of powerful friends. After a wandering and insecure life of some years in Italy, he accepted the invitation of the Cardinal Ippolyte d'Este to settle in Rome in 1559. In 1561 he revisited France, at the conference at Poissy. He returned to Rome in 1563. In 1578 the King of Poland invited him to teach jurisprudence at his new college at Cracow, but Gregory XIII. induced him to stay in Rome, where he died on June 4, 1585.

Complete editions of his works: editio princeps, Verona (1727–30); by D. Ruhnken (1789), by C. H. Frotscher (1834–41); two volumes of *Scripta selecta,* by J. Frey (1871); *Variae lectiones,* by F. A. Wolf and J. H. Fäsi (1791–1828). Muretus edited a number of classical authors with learned and scholarly notes. His other works include *Juvenilia et poemata varia, orationes* and *epistolae.*

See monograph by C. Dejob (Paris, 1881); J. E. Sandys, *Hist. Class. Schol.* (2nd ed., 1908), ii. 148–152.

MUREXIDE, an organic nitrogenous substance which crystallizes from water or alcohol in deep red plates or prisms with green metallic reflex. It owes its importance to the fact that it dissolves in water to a purple red solution or in aqueous caustic potash to a bluish purple. These colorations constitute the murexide test for uric acid. The reaction is effected by evaporating either uric acid or urinary calculi containing this acid with dilute nitric acid. The residue is treated with ammonia and aqueous caustic potash, when the foregoing colorations are developed. Murexide, $NH_4{\cdot}C_8H_4O_6N_5,H_2O$, is the ammonium salt of purpuric acid, $C_8H_5O_6N_5$, its constitution being expressed by the following formula (M. Slimmer and J. Stieglitz, 1904):



it is prepared by heating alloxantin (*q.v.*) with alcoholic ammonia (W. N. Hartley, 1905).

MURFREESBORO, a city of central Tennessee, U.S.A., 32 m. S.E. of Nashville, near the Stone river, at an altitude of 616 ft.; county seat of Rutherford county. It is on Federal highways 41 and 270 and the Nashville, Chattanooga and St. Louis railway. Pop. (1920) 5,367 (37% negroes); 7,993 in 1930 by the Federal census. Murfreesboro is the seat of Tennessee college (Baptist; 1906), the Middle Tennessee State Teachers college (1911), and one of the "child health demonstrations" of the Commonwealth fund. For half a century it has been the largest red-cedar market of the world, and is an important shipping point for cotton, live stock and dairy products and a large wholesale distributing centre for groceries and general merchandise. There are five cotton gins, a co-operative creamery making 2,000,000 pounds of butter in a year, and 27 diversified manufacturing plants. A city-manager form of government has operated since 1920. Murfreesboro was named after Col. Hardy Murfree, a Revolutionary officer who lived in Tennessee after 1807. It was incorporated in 1811, and from 1819 to 1825 was the capital of the State, which was then moved to Nashville by a majority of only one vote in the legislature. The battle of Murfreesboro (Stone's river) was fought on Dec. 31, 1862, and Jan. 2, 1863, about 2 m. N.W. of the city. The battlefield is now a national military park. On July 13, 1862, Gen. Nathan B. Forrest, in one of his brilliant raids, captured the city from the Federals. It was the birthplace of "Charles Egbert Craddock" (Mary N. Murfree).

MURGER, HENRY (1822–1861), French man of letters, was born in Paris. His father was a German *concierge* and a tailor. Murger became secretary to Count Alexei Tolstoi. In 1848 appeared his collected sketches called *Scènes de la vie de Bohême.* This book describes the fortunes and misfortunes, the loves, studies, amusements and sufferings of a group of impecunious students, artists and men of letters, of whom Rodolphe represents Murger himself. Murger belonged to a clique of so-called Bohemians, the most remarkable of whom, besides himself, were Privat d'Anglemont and Champfleury. *La Vie de Bohême,* arranged for the stage in collaboration with Théodore Barrière, was produced at the Variétés on Nov. 22, 1849, and was a triumphant success; it formed the basis of Puccini's opera, *La Bohême* (1898). Murger was a fastidious and capricious worker, and his years of hardship and dissipation had impaired his health. He published among other works *Claude et Marianne* in 1851; a comedy, *Le Bonhomme Jadis* in 1852; *Le Pays Latin* in 1852; *Adeline Protat* (one of the most graceful and innocent if not the most original of his tales) in 1853; and *Les Buveurs d'eau* in 1855. Some years before his death, which took place in a *maison de santé* near Paris on Jan. 28, 1861, Murger went to live at Marlotte, near Fontainebleau, where he wrote *Le Sabot rouge* (1860).

See an article by A. de Pontmartin in the *Revue des deux mondes* (Oct., 1861).

MURGHAB, a river of Afghanistan, which flows into Russian territory. It rises in the Firozkhoi highlands, the northern scarp of which is defined by the Band-i-Turkestan, and after traversing that plateau from east to west it turns north through deep defiles to Bala Murghab. Beyond this, in the neighbourhood of Maruchak, it forms for a space the boundary-line between

Afghan and Russian Turkestan; then joining the Kushk river at Pul-i-Khishti (Tash Kupri) it runs north to Merv, losing itself in the sands of the Merv desert after a course of about 450 m., its exact source being unknown.

MURIATIC ACID: *see* Hydrochloric Acid.

MURILLO, BARTOLOME ESTEBAN (1617–1682), Spanish painter, son of Gaspar Esteban Murillo and Maria Perez, was born at Seville in 1617, and baptized on Jan. 1, 1618. His parents (the father an artisan of a humble class), placed him under the painter Juan de Castillo, who was an imitator of the Italian School. Castillo's removal to Cadiz in 1639–1640 threw his pupil upon his own resources. He was compelled to earn his bread by painting rough pictures for the "feria" or public fair of Seville. The religious daubs exposed at that mart were generally of as low an order as the prices paid for them. This rough and ready practice, partly for the market-place, partly for converts in Mexico and Peru, for whom Madonnas and popular saints were produced and shipped off by the dozen, doubtless increased Murillo's dexterity. To this early period belong the Madonna giving the rosary to St. Dominicus in the Archbishop's palace at Seville; a "Madonna" in the Seville Museum, dark in colour and "Fray Lauterio before the Madonna" in the Fitzwilliam Museum, Cambridge. Murillo's works at this period are somewhat harsh in execution, but above the average reached by his contemporaries at Seville. Struck by the improvement which travel had wrought upon the style of his brother artist Pedro de Moya, Murillo in 1642 resolved to make a journey to Flanders or Italy. He placed his sister, who was dependent on him, under the care of some friends, and set out for Madrid. On reaching the capital he waited on Velazquez, his fellow-townsman—then at the summit of his fortune—and asked for introduction to friends in Rome. The master offered him lodging in his own house, and procured him admission to the royal galleries of the capital. Murillo here enjoyed the masterpieces of Italy and Flanders. The next two years were chiefly spent in copying from Ribera, Vandyck and Velazquez; and in 1644 Velazquez submitted some of Murillo's efforts to the king.

His patron urged him to go to Rome, but Murillo preferred to return to his sister and his native Seville. The friars of the convent of San Francesco in Seville had about this time determined to adorn the walls of their small cloister. But the brotherhood had no money, and found themselves incapable of employing an artist of name. Murillo offered his services, and covered the walls with eleven large pictures of remarkable power and beauty. Among them were representations of San Francisco, of San Diego, of Santa Clara and of San Gil. These pictures were executed in his earliest style, commonly called his *frio* or cold style. It is remarkable for solidity of workmanship, and in certain passages recalls the realism of Zurbaran and the young Velazquez.

In 1648 Murillo married a wealthy lady of rank, Doña Beatriz de Cabrera y Sotomayor, and his house soon became the favourite resort of artists and connoisseurs. Murillo now painted the well-known "Flight into Egypt," and shortly afterwards developed his *calido* or warm style. His outlines became softer and his figures rounder, and his colouring gained in warmth and transparency. In 1655 he executed his two famous paintings of "San Leandro" and "San Isidoro" at the order of Don Juan Federigo, archdeacon of Carmona, which are now in the cathedral of Seville. These are two noble portraits, finished with great care and admirable effect. His next picture, the "Nativity of the Virgin," painted for the cathedral, is one of the most delightful specimens of his *calido* style. It was taken by Marshal Soult, and is now in the Louvre. In the following year (1656) he painted a vast picture of San Antonio de Padua, one of his most celebrated performances, which still hangs in the baptistery of the cathedral.

The year 1665 saw him engaged on two large semicircular pictures, designed by his friend and patron Don Hustino Neve y Yevenes, to adorn the walls of the church of Santa Maria la Blanca. The first two (now in Madrid) were meant to illustrate the history of the Festival of Our Lady of the Snow, or the foundation of the Roman basilica of Santa Maria Maggiore. They belong to the first productions of the master, and denote the commencement of Murillo's third and last style, known as the *vaporoso* or vapoury. It should be noted, however, that the three styles are not strictly separable into date-periods. In the *vaporoso* method the well-marked outlines and careful drawing of his former styles disappear, the outlines are lost in the misty blending of the light and shade. The remaining pieces executed for this small church were a "Virgin of the Conception" and an "Allegory of Faith." Soult laid his hands on these also, and the former is now in the Louvre, the latter with Mr. Lyne Stephens, Lynford Hall, Norfolk.

HIS GREATEST WORKS

In 1658 Murillo consummated a task which had hitherto baffled all the artists of Spain, and even royalty itself. This was the establishing of a public academy of art. By superior tact he overcame the vanity of Valdes Leal and the presumption of the younger Herrera, and secured their co-operation. The Academy of Seville was accordingly opened for the first time in January 1660, and Murillo and the second Herrera were chosen presidents. Passing over some half-length pictures of saints and a dark-haired Madonna, painted in 1668 for the chapter-room of the cathedral of his native city, we enter upon the most splendid period of Murillo's career. In 1661 Don Miguel Mañara Vicentelo de Leca resolved to raise money for the restoration of the dilapidated Hospital de la Caridad. Mañara commissioned Murillo to paint eleven pictures for this edifice of San Jorge.

Three of these pieces represented the "Annunciation," the "Infant Saviour," and the "Infant St. John"; the remaining eight are considered Murillo's masterpieces. They consist of "Moses striking the Rock," the "Return of the Prodigal" (now at Stafford House), "Abraham receiving the Three Angels" (also at Stafford House) and "The Charity of San Juan de Dios," the "Miracle of the Loaves and Fishes," "Our Lord healing the Paralytic" (now at Orwell Park), "St. Peter released from Prison by the Angel" (now at the Hermitage, Leningrad) and "St. Elizabeth of Hungary." These works occupied the artist four years, and in 1674 he received for his eight great pictures 78,115 reals. The "Moses," the "Loaves and Fishes," the "San Juan," and the three subjects which we have named first, are still at Seville, the French carried off the rest, but the "St. Elizabeth" is now back in Spain. For compass and vigour the "Moses" stands first; but the "Prodigal's Return" and the "St. Elizabeth" were considered by Bermudez the most perfect of all as works of art. The front of this famous hospital was also indebted to the genius of Murillo; five large designs in blue glazed tiles were executed from his drawings.

He had scarcely completed the undertakings for this edifice when his favourite Franciscans again solicited his aid. He accordingly executed 18 paintings for the humble little church known as the Convent de los Capuchinos. Most of these Capuchin pictures are preserved in the Museum of Seville; the "Charity of St. Thomas of Villanueva" is reckoned the best. Murillo himself was wont to call it "su lienzo" (his own picture). One of this series "The Young St. Thomas of Villanueva distributing his Garments" is now in the Cincinnati Museum; and the altar piece representing "The Rose of St. Francis" is at the Cologne Museum. Another piece of extraordinary merit, which once hung in this church, is the "Virgin of the Napkin," believed to have been painted on a "servilleta" and presented to the cook of the Capuchin brotherhood as a memorial of the artist's pencil. In 1678 his friend the canon Justino again employed him to paint three pieces for the Hospital de los Venerables; the "Mystery of the Immaculate Conception" (taken by Marshal Soult and now in the Louvre), "St. Peter Weeping," and the "Blessed Virgin." As a mark of esteem Murillo next painted a full-length portrait of the canon (now with Lord Lansdowne); the spaniel at the feet of the priest has been known to call forth a snarl from a living dog. His portraits generally, though few, are of great beauty. One of the finest is the full-length portrait of his son now with the Duke of Alva at Madrid. The portrait of King Ferdinand the Saint is in the Elkins Collection, New York.

Towards the close of his life Murillo executed a series of pic-

tures illustrative of the life of "the glorious doctor" for the Augustinian convent at Seville. Mounting a scaffolding one day at Cadiz (in 1681) to execute the higher parts of a large picture of the "Espousal of St. Catherine," on which he was engaged for the Capuchins of that town, he stumbled, and received a hurt from which he never recovered. He died on April 3, 1682, in the arms of Pedro Nuñez de Villavicencio, one of his best pupils. Another of his numerous pupils was Sebastian Gomez, named "Murillo's Mulatto." Murillo left two sons (one of them at first an indifferent painter, afterwards a priest) and a daughter. He was buried in the Santa Cruz church near a picture by Pedro de Compaña where he was wont to pray.

Murillo has always been one of the most popular of painters—nor in Spain alone. His art was in accord with the taste of the mystical and devout people of his provincial neighbourhood; and his ecstasies of Madonnas and Saints are the themes of some of his most celebrated achievements. His subjects may be divided into two great groups—his street children, and the legendary and religious works. The former, of which some salient specimens are in the Dulwich Gallery, are delightful genre pictures.

Seville must still be visited by persons who wish to study Murillo thoroughly. A large number of the works which used to adorn this city have, however, been transported elsewhere. In the Prado Museum at Madrid are forty-five specimens of Murillo —the "Infant Christ and the Baptist" (named "Los Niños della Concha"), "St. Ildefonso vested with a Chasuble by the Madonna," etc.; in the Museo della Trinidad, "Christ and the Virgin appearing to St. Francis in a Cavern" and various others. In the National Gallery, London, the chief example is the "Holy Family"; this was one of the master's latest works, painted in Cadiz.

Alfonso, *Murillo, el hombre,* etc. (1886); C. Justi, *Murillo* (illustrated, 1892); P. Lefort, *Murillo et ses élèves* (1892); F. M. Tubino, *Murillo, su epoca,* etc. (1864, Eng. trans., 1879); Dr. G. C. Williamson, *Murillo* (1902); C. S. Ricketts, *The Prado* (1903); A. L. Mayer, *Murillo* (Stuttgart Berlin, 1913).

MURMANSK, a port on the Kola inlet of the Murmansk coast of the Barents sea in the Russian S.F.S.R. in 69° 10′ N., 33° 30′ E. Pop. (1926) 8,777. In 1916 it was merely a few log huts, but the completion of a railway line linking it with Leningrad has led to a remarkably rapid development, since it is the only northerly port of the U.S.S.R. which is ice-free all the year round. There is sheltered anchorage for large vessels and its loading and unloading capacity is 3,000 tons per day. It has ample storehouses and railway sidings, tugs, water-boats, lighters, etc. Workmen's dwellings of modern type are being erected and there is a municipal electricity and water-supply, and a hospital. Its industries are mainly dependent on the fishing industry, and cod liver oil, fish-guano, and shagreen from shark skin are produced. A carpentry industry is carried on in winter to supply barrels and boxes for fish. Prospects of an import trade from Great Britain, U.S.A. and Canada are good, and American cotton for Moscow already comes via Murmansk.

The Murmansk coast extends from the Russian frontier to Cape Svyatoi Nos. It is a region of granitic cliffs 1,000 ft. in the west and 300 ft. at Svyatoi Nos, indented by deep gulfs and inlets with tundra and stunted bushes, and has many excellent harbours. The Atlantic drift warms the coast and west of Litski point there is little pack-ice and, though a thin ice crust may form, it does not impede navigation, and thus this coast, lying within the Arctic circle, is open all the year round. Ice-breakers are rarely needed. There are telegraph lines, wireless stations and lighthouses. Fishing is the main occupation, and the season lasts from March to August. The fish comes from Norway and so the fishing moves from west to east. Not only are the local inhabitants employed, but about 3,000 men from the Kem and Onega district come for the season, and need no longer endure a long sledge journey.

The chief fish caught are cod (treska), turbot, haddock, coal fish or saith, wolf-fish, flat fish, comber or sea perch, eel and pout. Herrings are common but are not in much demand. Sharks are caught and oil extracted from their liver is used for medicinal purposes, and their skin is dressed. Deficiency of salt gave Murmansk fish a bad name, but government salt depôts now exist and the fish is satisfactorily cured. Alexandrovsk, at the mouth of the Kola inlet, on the western side, was opened as a port in 1899, but its site proved unsuitable owing to its single inlet and to the steep rocks near the harbour, and Murmansk has displaced it. The Murmansk administrative district includes the Kola peninsula and is part of the Leningrad Area, though it is divided from it by the Karelian A.S.S.R.; it has an area of 128,600 sq.km. and a population (1926) of 23,016.

MURNER, THOMAS (1475–1537?), German satirist, was born on Dec. 24, 1475 at Oberehnheim near Strasbourg. In 1518–19 he studied law at Basel. He entered the Franciscan order in 1490, and in 1495 wandered over Europe, making enemies by his scurrilous tongue. In 1533 he was appointed priest of Oberehnheim, where he died about 1537.

There is not a trace of human kindness in Murner's satires; they were directed against the corruption of the times, the Reformation, and especially against Luther, and the most powerful—the most virulent German satire of the period—is *Von dem grossen lutherischen Narren, wie ihn Dr. Murner beschworen hat.* Among others are *Die Narrenbeschwörung* (1512); *Die Schelmenzunft* (1512); *Die Gäuchmatt,* which treats of enamoured fools (1519), and a translation of Virgil's *Aeneid* (1515) dedicated to Maximilian I. Murner also wrote the humorous *Chartiludium logicae* (1507) and the *Ludus studentum freiburgensium* (1511), besides a translation of Justinian's *Institutiones* (1519).

All Murner's more important works have been republished in critical editions; a selection appeared in Kürschner's *Deutsche Nationalliteratur* (1890). *Cf.* W. Kawerau's *Murner und die Kirche das Mittelalters* (1890), and *Murner und die deutsche Reformation* (1891); also Liebenau, *Der Franziskaner Dr. Th. Murner* (1913).

MUROM, a town of Russia in the Vladimir province, in 55° 32′ N., 42° 2′ E., on the Oka, near its confluence with the Tesha. It is on the railway from Moscow to the east, and has a branch going north to Kovrov. Its pop. (1926) 22,621, has nearly doubled in the last 25 years. It has iron smelting works, a railway repairing yard, leather, oil-pressing, cotton and flax-spinning and brandy factories. Grain is unloaded from the lower Oka. The district is famous for its kitchen gardens and cucumbers.

MURPHY, ARTHUR (1727–1805), Irish actor and dramatist, son of a Dublin merchant, was born at Clomquin, Roscommon, on Dec. 27, 1727, and studied at the English college at St. Omer. He went on the stage in 1754. He appeared in the title-rôles of *Richard III.* and *Othello;* as Biron in Southerne's *Fatal Marriage;* and as Osmyn in Congreve's *Mourning Bride.* His first farce, *The Apprentice,* was given at Drury Lane on Jan. 2, 1756. It was followed, among other plays, by *The Upholsterer* (1757), *The Orphan of China* (1759); *The Way to Keep Him* (1760), *All in the Wrong* (1761), *The Grecian Daughter* (1772), and *Know Your Own Mind* (1777). Most of these were adaptations from the French. Murphy edited a political periodical, called the *Test,* in support of Henry Fox, by whose influence he was called to the bar at Lincoln's Inn, although he had been refused at the Middle Temple in 1757 on account of his connection with the stage. Murphy also wrote a biography of Fielding, an essay on the life and genius of Samuel Johnson and translations of Sallust and Tacitus. Towards the close of his life the office of a commissioner of bankrupts and a pension of £200 were conferred upon him by Government. He died on June 18, 1805.

MURPHY, JOHN B. (1857–1916), American physician, was born in Appleton, Wis., on Dec. 21, 1857. He graduated at Rush Medical college in 1879 and studied in Europe from 1882 to 1884. He invented the anastomosis button (1892), which simplified the technique of abdominal operations and so reduced their danger. Dr. Murphy also attained eminence at a teacher of surgery. He taught successively at Rush Medical college, the College of Physicians and Surgeons and at Northwestern University Medical school. In 1911 he was president of the American Medical Association. He wrote *General Surgery,* which is vol. ii. of the Practical Medical Series, and numerous articles for medical journals.

MURPHY, JOHN FRANCIS (1853–1921), American landscape painter, was born at Oswego, N.Y., on Dec. 11, 1853. He first exhibited at the National Academy of Design in 1876, and was made an associate in 1885, and a full academician two years later. He became a member of the Society of American Artists (1901) and of the American Water Color Society. He died in New York city on Jan. 10, 1921.

MURPHYSBORO, a city of south-western Illinois, U.S.A., on the Big Muddy river, 10 m. from the Mississippi; the county seat of Jackson county. It is served by the Illinois Central, the Missouri Pacific and the Mobile and Ohio railways. Pop. (1920) 10,703 (85% native white, 10% negro); and 8,182 in 1930 by the Federal census. It is in a rich agricultural region; coal, shale and silica are mined in the vicinity; and the city has various manufacturing industries, with an output in 1925 valued at $2,850,769. Murphysboro was settled in 1850 and incorporated in 1867. It was the birthplace of General John A. Logan.

MURRAIN, *see* Rinderpest; Pleuro-pneumonia; Anthrax; and Foot and Mouth Disease. *See* also Veterinary Science.

MURRAY or **MORAY, EARLS OF.** The earldom of Moray was one of the seven original earldoms of Scotland, its lands corresponding roughly to the modern counties of Inverness and Ross. Little is known of the earls until about 1314, when Sir Thomas Randolph, nephew of King Robert Bruce, was created earl of Moray (*q.v.*). When the childless John Randolph, 3rd earl, was killed at the battle of Neville's Cross in 1346, it is not certain who held the earldom until 1359 when Henry Plantagenet, duke of Lancaster (d. 1361), was made earl of Moray by King David II. In 1372, however, John Dunbar (d. 1391), a grandson of Sir Thomas Randolph and a son-in-law of Robert II., obtained the earldom. The last of the Dunbar earls was James Dunbar, who was murdered in August 1429, and after this date his daughter Elizabeth and her husband, Archibald Douglas (d. 1455), called themselves earl and countess of Moray.

James IV. created his natural son, James Stuart (*c.* 1499–1544), earl of Moray, and after the title had been borne for a short time by George Gordon, 4th earl of Huntly (*c.* 1514–1562), it was bestowed in 1562 by Mary Queen of Scots upon her half-brother, an illegitimate son of James V. This was the famous regent, James Stuart, earl of Moray, or Murray (*q.v.*), murdered, Jan. 1570.

See vol. vi. of R. Douglas's *Peerage of Scotland,* new ed. by J. B. Paul (1909).

MURRAY, SIR DAVID (1849–), Scottish painter, was born in Glasgow. He became A.R.A. in 1891, and R.A. in 1905, and was a member of many important societies. In 1917 he was made president of the Royal Institute of Painters of Water Colours, and in the following year he was knighted. Two of his pictures, "My Love is gone a-sailing" (1884) and "In the Country of Constable" (1903), are in the National Gallery of British Art. "Young Wheat," painted in 1890, is one of his most noteworthy works. Among his other pictures are: "River Road"; "Mangolds"; "Gorse"; "Hampshire"; a series of pictures in Picardy, the Italian lakes, Venice, the Trossachs, the Isle of Lewis, and sea-pieces from the Dorset coast.

MURRAY, EUSTACE CLARE GRENVILLE (1824–1881), English journalist, was born in 1824, the natural son of the 2nd duke of Buckingham. Educated at Magdalen hall (Hertford college), Oxford, he entered the diplomatic service. He was attaché at Vienna, where he lost his post for arranging to act as correspondent to a London paper. In 1868 he returned to England, and devoted himself to journalism. He founded (1869) an abusive society paper, the *Queen's Messenger.* For a libel published in this paper Lord Carrington horsewhipped him on the doorstep of a London club. Murray was subsequently charged with perjury for denying on oath his authorship of the article. Remanded on bail, he escaped to Paris, where he acted as correspondent to London papers. In 1874 he helped Edmund Yates to found the *World.* Murray died at Passy on Dec. 20, 1881.

MURRAY, LORD GEORGE (1694–1760), Jacobite general, fifth son of John, 1st duke of Atholl, was born at Huntingtower, near Perth, on Oct. 4, 1694. He joined the army in Flanders in 1712 and in 1715 the Jacobite rebels under the earl of Mar. Wounded at the battle of Glenshiel in 1719, he escaped to Rotterdam some months later. In 1724 he returned to Scotland, and on being granted a pardon, settled at Tullibardine until 1745, when on the eve of the Jacobite rising the duke of Perth approached him on behalf of the Pretender; but his attitude was doubtful. He paid his respects to Sir John Cope, the commander of the government troops, and permitted his brother, the duke of Crieff, to appoint him deputy-sheriff of Perthshire. He received a commission in the Jacobite army and the victory at Prestonpans, on Sept. 21, was practically due to his able generalship. After opposing the invasion of England, he prevailed on the prince to march into Cumberland. When Carlisle was lost, he resigned his command, but the dissatisfaction of the army with his successor, the duke of Perth, compelled Charles to reinstate Murray. Obliged to retreat from Derby, his army reached Carlisle safely and in January 1746 entered Stirling.

The prince laid siege to Stirling Castle, while Murray defeated General Hawley near Falkirk; but the losses of the Jacobites by sickness and desertion, and the approach of Cumberland, made retreat to the Highlands an immediate necessity. The battle of Culloden, where the Stuart cause was ruined, was fought on the 16th of April 1746. On the following day the duke of Cumberland intimated to his troops that "the public orders of the rebels yesterday was to give us no quarter"; and Hanoverian news-sheets printed what purported to be copies of such an order. The original copies of Lord George Murray's "orders at Culloden" which are in existence, contain no injunction to refuse quarter. After the defeat Murray conducted a remnant of the Jacobite army to Ruthven, but Prince Charles had determined to abandon the enterprise, and dismissed Murray from his service. Charles's belief in the general's treachery was shared by several leading Jacobites, but there appears no ground for the suspicion. Murray escaped abroad and died in Holland on Oct. 11, 1760.

See *A Military History of Perthshire,* ed. by the marchioness of Tullibardine (2 vols., 1908); *The Atholl Chronicles,* ed. by the duke of Atholl (privately printed); The Chevalier James de Johnstone, *Memoirs of the Rebellion in 1745* (3rd ed., 1822); J. Ray, *Complete History of the Rebellion, 1745–1746* (1754); R. Patten, *History of the late Rebellion* (2nd ed., 1717); *Memoirs of Sir John Murray of Broughton,* ed. by R. F. Bell (Edinburgh, 1898); A. Henderson, *History of the Rebellion, 1745–1746* (2nd ed., London, 1748); W. Duke, *Lord George Murray and the Forty-five* (1927).

MURRAY, GILBERT (1866–), British classical scholar, was born at Sydney, N.S.W., Jan. 2, 1866, but left Australia at the age of 11. He was educated at Merchant Taylors' school, London, and St. John's college, Oxford. At Oxford he won the Hertford and Ireland scholarships (1885), the Craven scholarship (1886), the prize for Latin verse (1886) and the Gaisford prizes for Greek verse and prose (1886–87). He was elected to a fellowship at New college, Oxford, in 1888, and next year to the professorship of Greek at Glasgow university, a position he held till 1899. In 1908 he was appointed Regius professor of Greek at Oxford. In 1889 he had married Lady Mary Howard, daughter of the 9th earl of Carlisle. He contested Oxford university several times in the Liberal interest, but it was a forlorn hope. He is a member of the British Academy and of many foreign learned societies.

Murray was a keen worker for international understanding, and after the World War he sat in the Foreign Office committee concerned with drafting the Covenant of the League of Nations. He attended the Assembly in 1921, 1922 and 1923 as a member of the South African delegation, and in 1924 as a member of the British delegation. He has been, from the beginning, the British member of the committee of intellectual co-operation, and was its president in 1928. Among other departments of the work of the League he was specially interested in the protection of minorities. He was one of the promoters of the League of Nations Union, of which he was chairman from 1918 to 1919, and again from 1923 onwards.

Murray published a *History of Ancient Greek Literature* in 1897. He is best known to the general reader by his incomparable renderings of the plays of Euripides into English verse. Several

of his versions were acted in England and America. Indeed he may be said to have brought Greek drama back to the modern stage. He also published *The Rise of the Greek Epic* (1907; 2nd ed., 1911, 3rd ed., 1924) and *Four Stages of Greek Religion* (1913, 2nd ed., under the title *Five Stages . . .*, 1925). Amongst his works on other subjects are *The Foreign Policy of Sir Edward Grey* (1915); *Faith, War and Policy* (1918); *Religio Grammatici* (1918); and *Problem of Foreign Policy* (1921); *Euripides and his Age* (1918); *The Stoic Age* (1915); *The Classical Tradition in Poetry* (1927); *Ordeal of This Generation* (1929), etc. He wrote for the present edition of the *Encyclopædia Britannica* the articles: EURIPIDES, HOMER and DRAMA, *Greek* (in part).

MURRAY, JAMES (*c.* 1719–1794), British governor of Canada, was a younger son of Alexander Murray, 4th Lord Elibank (d. 1736). He commanded a brigade at the siege of Louisburg, was one of Wolfe's three brigadiers in the expedition against Quebec, and commanded the left wing of the army in the famous battle in Sept. 1759. After the British victory and the capture of the city, Murray was left in command of Quebec, which he defended in April and May 1760 against the attacks of the French, forcing them to raise the siege.

In Oct. 1760 Murray was appointed governor of Quebec, and he became governor of Canada after its formal cession to Great Britain in 1763. In this year he quelled a dangerous mutiny. In 1766 he retired owing to charges of partiality to the French Canadians but was exonerated in the House of Lords. In 1774 Murray was sent to Minorca as governor, where he was besieged in Fort St. Philip by a large force of French and Spaniards in 1781, and was obliged to surrender after seven months' resistance. On his return to England he was tried by a court-martial, at the instance of Sir William Draper, who had served under him in Minorca as lieutenant-governor. He was acquitted and he became a general in 1783. He died on June 18, 1794.

MURRAY, SIR JAMES AUGUSTUS HENRY (1837–1915), British lexicographer, was born at Denholm, near Hawick, on Feb. 7, 1837. After a local elementary education he proceeded to Edinburgh, and thence to the University of London, where he graduated in 1873. Sir James Murray, who received honorary degrees from several universities, both British and foreign, was engaged in teaching for 30 years, from 1855 to 1885, chiefly at Hawick and Mill Hill. During this time his reputation as a philologist was increasing; in 1878 he wrote his famous article on English Language for the *Encyclopædia Britannica,* and he was president of the Philological Society of London from 1878 to 1880, and again from 1882 to 1884. It was in connection with this society that he undertook the chief work of his life, the editing of the *New English Dictionary,* based on materials collected by the society (*see* DICTIONARY). These materials, which had accumulated since 1857, when the society first projected the publication of a dictionary on philological principles, amounted to an enormous quantity, of which an idea may be formed from the fact that Dr. Furnivall sent in "some ton and three-quarters of materials which had accumulated under his roof." The contracts between the society, the delegates of the Clarendon Press, and the editor, were signed on March 1, 1879, and Murray began the examination and arrangement of the raw material, and the still more troublesome work of re-animating and maintaining the enthusiasm of "readers." In 1885 he removed from Mill Hill to Oxford, where his *Scriptorium* came to rank among the institutions of the university city. The first volume of the dictionary was printed at the Clarendon Press, Oxford, in 1884. Murray himself was personally responsible only for about one-half of the dictionary, covering A–D, H–K, O, P, T. But he created the organization which made the undertaking possible, and inspired both his colleagues and successors. In 1885 Murray received the honorary degree of M.A. from Balliol college; he was an original fellow of the British Academy, and in 1908 he was knighted. He died at Oxford on July 26, 1915.

See a memoir by Henry Bradley in *Proceedings of the Brit. Acad.* (vol. viii., 1917–18).

MURRAY or **MORAY, JAMES STUART,** EARL OF (*c.* 1531–1570), regent of Scotland, was an illegitimate son of James V. of Scotland by Margaret Erskine, daughter of the earl of Mar. In 1538 he was appointed prior of the abbey of St. Andrews in order that James V. might secure its funds, and later, he also received those of Pittenweem and Mâcon in France, but manifested no vocation for a monastic life. In fact, shortly after the return of Knox to Scotland in 1559, he joined the lords of the congregation, who resolved to abolish forcibly the Roman service. In 1562 he was created earl of Murray, a dignity also held by George Gordon, earl of Huntly, who, however, had lost the queen's favour. Only a few days later he was made earl of Mar, but as this title was claimed by John, Lord Erskine, Stuart resigned it.

Murray displeased the queen, his half-sister, by his efforts in behalf of Knox now accused of high treason; and as he was also opposed to her marriage with Darnley, he was after that event declared an outlaw and took refuge in England. Returning to Scotland after the murder of Rizzio, he was pardoned by the queen. After her abdication in 1567, he was appointed regent of Scotland, and defeated the queen's forces at Langside, near Glasgow (May 13, 1568). He baffled Mary's schemes, suppressed the border thieves, and ruled firmly, resisting the temptation to place the crown on his own head while Mary remained a captive under suspicion of complicity in the murder of Darnley.

Several events occurred for which Murray has been censured, but which were necessary for his security: the betrayal to Elizabeth of the duke of Norfolk and of the secret plot for the liberation of Mary; the imprisonment of the earl of Northumberland, who after the failure of his rising in the north of England had taken refuge in Scotland; and the charge brought against Maitland of Lethington of complicity in Darnley's murder. Lethington was committed to custody, but was rescued by Kirkaldy of Grange, who held the castle of Edinburgh. Murray was afraid to proceed with the charge on the day of trial, while Kirkaldy and Maitland held the castle, which became the stronghold of the deposed queen's party. It has been suspected that Maitland and Kirkaldy were cognizant of the design of Hamilton of Bothwellhaugh to murder Murray, for he had been with them in the castle. As he rode through Linlithgow Murray was shot on Jan. 21, 1570, from a window by Hamilton.

See the various *Calendars of State Papers* and the general bibliography for Mary, Queen of Scots given in *Camb. Mediaeval Hist.* (vol. 3, chap. 8, 1904).

MURRAY, SIR JOHN (1841–1914), British geographer and naturalist, was born at Coburg, Ontario, Canada, on March 3, 1841. In 1868 he visited Spitsbergen on a whaler, and in 1872 he was appointed one of the naturalists to the "Challenger" expedition. He drew up the scientific results, and in 1882 he became editor of the *Reports* of the expedition. He compiled a summary of the results, and was part-author of the *Narrative of the Cruise* and of the *Report on Deep-sea Deposits.* He also published important papers on oceanography and marine biology. Murray took part in 1880 and 1882 in an exploration of the Faeroe Channel, and between 1882 and 1894 was the prime mover in various biological investigations in Scottish waters. In 1897, with the financial assistance of Laurence Pullar and a staff of specialists, he began a bathymetrical survey of the fresh-water lochs of Scotland. He took part in the expedition (1910) for the physiological and biological investigation of the North Atlantic Ocean. He was accidentally killed near Kirkliston, in Scotland on March 16, 1914.

MURRAY, JOHN, the name for several generations of a great firm of London publishers, founded by John McMurray (1745–1793), a native of Edinburgh and a retired lieutenant of marines, who in 1768 bought the book business of William Sandby in Fleet Street, and, dropping the Scottish prefix, called himself John Murray. He was one of the twenty original proprietors of the *Morning Chronicle,* and started the monthly *English Review* (1783–1796). Among his publications were Mitford's *Greece,* Langhorne's *Plutarch's Lives,* and the first part of Isaac D'Israeli's *Curiosities of Literature.* He died on Nov. 6, 1793.

JOHN MURRAY (2) (1778–1843), his son, was then fifteen. During his minority the business was conducted by Samuel Highley, who was admitted a partner, but in 1803 the partner-

ship was dissolved. Byron called him "the Anak of publishers." In 1807 he took a share with Constable in publishing *Marmion,* and became part owner of the *Edinburgh Review,* although with the help of Canning he launched in opposition the *Quarterly Review* (Feb. 1809), with William Gifford as its editor, and Scott, Canning, Southey, Hookham Frere and John Wilson Croker among its earliest contributors. Murray was closely connected with Constable, but, to his distress, was compelled in 1813 to break this association on account of Constable's business methods, which, as he foresaw, led to disaster. In 1811 the first two cantos of *Childe Harold* were brought to Murray by R. C. Dallas, to whom Byron had presented them. Murray paid Dallas 500 guineas for the copyright. In 1812 he bought the publishing business of William Miller (1769–1844), and migrated to 50 Albemarle street. Literary London flocked to his house, and Murray became the centre of the publishing world. It was in his drawing-room that Scott and Byron first met, and here, in 1824, after the death of Lord Byron, his memoirs manuscript, considered by Gifford unfit for publication, was destroyed. A close friendship existed between Byron and his publisher, and their correspondence is one of the chief literary documents of the period. For political reasons business relations ceased after the publication of the 5th canto of *Don Juan.* Murray paid Byron some £20,000 for his various poems. To Thomas Moore he gave nearly £5,000 for writing the life of Byron, and to Crabbe £3,000 for *Tales of the Hall.* He died on June 27, 1843.

His son, JOHN MURRAY (3) (1808–1892), began the famous series "Murray's Handbooks" for travellers; he himself wrote several volumes. (*See* his article on the "Handbooks" in *Murray's Magazine,* November 1880.) He published many books of travel; also Campbell's *Lives of the Chancellors, The Speaker's Commentary,* Smith's *Dictionaries;* and works by Hallam, Gladstone, Lyell, Layard, Dean Stanley, Borrow, Darwin, Livingstone and Samuel Smiles. He died on April 2, 1892, and was succeeded by his eldest son, SIR JOHN MURRAY (4) (1851–1928), under whom, in association with his brother, A. H. Hallam Murray, the firm was continued. Sir John Murray edited Gibbon's Autobiography and Byron's Correspondence. He died Nov. 30, 1928.

See Samuel Smiles, *A Publisher and his Friends, Memoirs and Correspondence of the late John Murray* . . . (1891), for the second John Murray; a series of three articles by F. Espinasse on "The House of Murray," in *The Critic* (Jan. 1860); and a paper by the same writer in *Harper's New Monthly Magazine* (Sept. 1885). *See* the *Letters and Journals* of Byron (ed. Prothero, 1898–1901).

MURRAY, LINDLEY (1745–1826), Anglo-American grammarian, was born at Swetara (Penn.), on April 22, 1745. He practised law until the Revolution; then made a fortune with his father's aid by catering to the British during their occupation of New York. After his retirement to Holdgate, England, he devoted himself to writing until his death on Feb. 16, 1826. His *Grammar of the English Language* (1795) and the corresponding *English Exercises* and *Key* (both 1797) as well as his other texts had an extraordinary sale, some of them running into scores of editions of ten or twelve thousand each. The Grammar was studied by the historian Prescott as a literary preparation.

BIBLIOGRAPHY.—*See* the *Memoir,* autobiographical letters completed by Elizabeth Frank (1826), and the biography by W. H. Egle (1885).

MURRAY (or MORAY), SIR ROBERT (*c.* 1600–1673), one of the founders of the Royal Society, was the son of Sir Robert Murray, of Craigie, Ayrshire. He was educated at St. Andrew's, served in the French army, and in the Royalist ranks during the Civil War. In 1650 he was named lord justice clerk and a privy councilor, titles which were confirmed at the Restoration. Through his influence with the king he secured the incorporation by charter of the Royal Society on July 15, 1662. Murray was its first president. He died in London on July 4, 1673, and was buried in Westminster Abbey.

MURRAY COD (*Oligorus macquariensis*), one of the largest of the fresh-water perciform fishes of Australia, celebrated for its excellent flavour. It belongs to the family *Serranidae.* The shape is that of a perch, and the dorsal fin consists of two portions, spiny and rayed, the number of spines being eleven. The scales are small. The colour varies in different localities; it is generally brownish, with a greenish tinge and numerous small dark green spots. This fish has its headquarters in the Murray river and its tributaries, but occurs also in northern New South Wales. It is the most important food fish of these rivers, and may attain a length of more than 3ft. and a weight of 120 pounds.

MURRAY RIVER AND BASIN: *see* AUSTRALIA: *Drainage.* (*See* also ALEXANDRINA LAKE, ALBURY and RIVERINA.)

MURRE, the common name in U.S.A. for the guillemot (*q.v.*).

MÜRREN (5,415 ft.), a village in the Bernese Oberland, on the slopes of the Jungfrau, Switzerland. It is reached by a funicular railway and light railway, from Interlaken and Lauterbrunnen. The population is German-speaking and Protestant. The place is a famous health resort and winter sport centre.

MURSA, BATTLE OF (351 A.D.). In January 350, Magnentius the usurper deposed the Emperor Constans, and a little while after was opposed by Constantius, who decisively defeated him near Mursa in Pannonia on September 28, 351, and finally destroyed him two years later. The battle is of interest because the Romans adopted new tactics.

Behind Constantius flowed the Danube, and on his right lay the Drave; consequently flight was out of the question. On both wings he posted his mounted archers, and in the forefront his mailed cavalry organized after the Persian model. In the centre he drew up his heavy armed infantry, and in rear of them deployed his bowmen and slingers. His attack was made against the enemy's right wing, the whole of his left wing cavalry advancing in oblique order. When well on the outer flank of the enemy's right wing the cavalry wheeled inwards and charged with great effect, for the whole of Magnentius's line was thrown into confusion. The action now became general, and, though Magnentius fled, Marcellinus continued the fight, the Gauls of the Western Roman army refusing to surrender. It has been estimated that Magnentius lost 24,000 and Constantius 30,000. So great was the loss of the victor in veteran troops that after this battle it was not possible to find a sufficiency of trained men to defend the frontiers, let alone add new triumphs to Rome.

MURSHIDABAD, a town and district of British India, in the Presidency division of Bengal. The administrative headquarters of the district are at Berhampore (*q.v.*). The town of Murshidabad is on the left bank of the Bhagirathi, an old and sacred channel of the Ganges. Pop. (1921) 10,669. It was the latest Mohammedan capital of Bengal. In 1704 the nawab Murshid Kuli Khan changed the seat of government from Dacca to Maksudabad, which he called after his own name. Even after the conquest of Bengal by the British, Murshidabad remained for some time the seat of administration. The town is still the residence of the descendant of the Nawab Nazims of Bengal, who ranks as the first nobleman of the province, with the style of nawab bahadur of Murshidabad. His palace, dating from 1837, is a fine building in Italian style. A cemetery on the right bank of the river contains the tombs of Ali Vardi Khan and Sirajuddaula. The Imambara, built in 1847, is the largest in Bengal. Murshidabad still retains such industries as carving in ivory, gold and silver embroidery, and silk-weaving.

The DISTRICT OF MURSHIDABAD has an area of 2,121 sq.m. and a population (1921) of 1,487,572. It is divided into two nearly equal portions by the Bhagirathi. In the tract to the west, known as the Rarh, the general level is high, but interspersed with marshes and seamed by hill streams. The Bagri, or eastern half, is a low-lying alluvial plain liable to annual inundation. The principal industry is that of silk, but it is now declining.

MUS, the name of a Roman family of the plebeian Decian gens. (1) PUBLIUS DECIUS MUS in 343 B.C. rescued the Roman army from a difficulty in the Samnite War (Liv. vii. 34). In 340, as consul with T. Manlius Torquatus as colleague, he commanded in the Latin War. The decisive battle was fought near Mt. Vesuvius. The consuls, in consequence of a dream, had agreed that the general whose troops first gave way should devote himself to destruction, and so ensure victory. The left wing under

Decius became disordered, whereupon, repeating after the chief pontiff the solemn formula of self-devotion he dashed into the ranks of the Latins, and met his death (Livy viii. 9). (2) His son, also called PUBLIUS, consul for the fourth time in 295, followed the example of his father at the battle of Sentinum, when the left wing which he commanded was shaken by the Gauls (Livy x. 28).

MUSACEAE, in botany, the banana family, monocotyledonous plants divided into six genera and about 70 species, all tropical and mostly gigantic herbs. *Ravenala madagascariensis* is called the traveller's tree, as water accumulates in the leaf-bases and can be used for drinking. *Musa* includes the banana and plantain and also Manila hemp (*qq.v.*).

MUSAEUS, the name of three Greek poets. (1) The first was a mythical seer and priest, the pupil or son of Orpheus, who was said to have been the founder of priestly poetry in Attica. He composed hymns and prose treatises, and oracular responses, which were collected in the time of Peisistratus by Onomacritus. The mystic and oracular verses and customs of Attica, especially of Eleusis, are connected with his name (Herod. vii. 6; viii. 96; ix. 43). A *Titanomachia* and *Theogonia* are also attributed to him (G. Kinkel, *Epicorum graecorum fragmenta,* 1878). (2) The second was an Ephesian attached to the court of the kings of Pergamum, who wrote a *Perseis,* and poems on Eumenes and Attalus (Suïdas, *s.v.*). (3) The third (called Grammaticus in all the mss.) is of uncertain date, but probably belongs to the beginning of the 6th century A.D., as his style and metre are evidently modelled after Nonnus. He is possibly to be identified with the friend of Procopius who wrote a poem on Hero and Leander (editions by F. Passow, 1810; G. H. Schäfer, 1825; C. Dilthey, 1874; vl. by E. Sikes, London, 1920). It was imitated by Marlowe, among others, and has been translated into many languages. The little love-poem *Alpheus and Arethusa* (*Anthol. pal.* ix. 302) is also ascribed to Musaeus.

MUSÄUS, JOHANN KARL AUGUST (1735–1787), German author, was born at Jena. His first work, *Grandison der Zweite* (1760–62) afterwards (1781–82) rewritten and issued with a new title, *Der deutsche Grandison,* is a satire on Samuel Richardson's hero, who had many sentimental admirers in Germany. In 1763 Musäus was made master of the court pages at Weimar, and in 1769 he became a master at the Weimar gymnasium. His second book, *Physiognomische Reisen* (1778–79), was directed against Lavater. From 1782–86 he published his best work, *Volksmärchen der Deutschen.* Even in this series of tales, the substance of which Musäus collected among the people, he could not refrain from satire. The stories, therefore, lack the simplicity of genuine folk-lore. In 1785 was issued *Freund Heins Erscheinungen in Holbeins Manier* by J. R. Schellenberg, with explanations in prose and verse by Musäus. A collection of stories entitled *Straussfedern* (1787) was left unfinished at his death on Oct. 28, 1787.

The *Volksmärchen* have been frequently reprinted (Düsseldorf, 1903, etc.). They were translated into French in 1844, and three of the stories are included in Carlyle's *German Romance* (1827); Musäus's *Nachgelassene Schriften* were edited by his relative, A. von Kotzebue (1791). *See* M. Müller, *J. K. A. Musäus* (1867), and an essay by A. Stern in *Beiträge zur Literaturgeschichte des 18. Jahrhunderts* (1893).

MUSCAT, a town on the south-east coast of Arabia, capital of the independent State of Oman. It commands the entrance to the Persian gulf. In geographical position it is isolated from the interior of the peninsula as the mountains rise behind it in a rugged wall. It is only from Matrah, a northern suburb shut off by an intervening spur which reaches to the sea, that land communication with the rest of Arabia can be maintained. Both Muscat and Matrah are defended on the landward side by a wall with towers at intervals.

The early history of Muscat is the history of Portuguese ascendancy in the Persian gulf. When Albuquerque burnt the place after destroying Karyāt in 1508, Kalhat was the chief port of the coast and Muscat was comparatively unimportant. Kalhat was subsequently sacked and burnt. For 114 years Muscat was held as a naval station and factory during a period of local revolts, Arab incursions, and Turkish invasion by sea; but it was not till 1622, when the Portuguese lost Hormuz, that Muscat became the headquarters of their fleet and the most important place held by them on the Arabian coast. In 1650 the Portuguese were finally expelled from Oman. Muscat had been reduced after a siege in 1648. The Persians next occupied Oman, but left it in 1741. Under the great ruler of Oman, Said ibn Sultan (1804–1856), the fortunes of Muscat attained their zenith; but on his death, when his kingdom was divided and the African possessions were parted from western Arabia, Muscat declined. In 1883–84, when Turki was sultan, the town was unsuccessfully besieged by the Indabayin and Rehbayin tribes, led by Abdul Aziz, the brother of Turki. The sultan's palace is near the centre of the town, a relic of Portuguese occupation, called by the Arabs El Jereza, a corruption of Igrezia (church). This term is probably derived from the chapel once attached to the buildings which formed the Portuguese governor's residence and factory.

The towns of Muscat and Matrah have a very small Arab population, Baluchis and negroes being by far the most numerous. Muscat and Matrah have together about 20,000 inhabitants. Muscat imports rice, coffee and cotton goods and exports dates, pomegranates and dried fish. The British residency stands on a low sandy isthmus which connects the fortress of Jalāli with the mainland.

MUSCATINE, a city of eastern Iowa, U.S.A., on the Mississippi river, at the southern end of the "big bend"; the county seat of Muscatine county. It is on the Mississippi river scenic highway; has an airport; and is served by the Chicago, Milwaukee, St. Paul and Pacific, the Clinton, Davenport and Muscatine, the Burlington, Muscatine and Northwestern, and the Rock Island railways, and river barges. Pop. (1920) 16,068 (89% native white); 1930 Federal census 16,778. The city has an area of 7 sq.m., rising from the river to the bluffs which here make a semicircular détour away from the river banks. Its most distinctive industry (established in 1891 by J. F. Boepple, a German) is the manufacture of pearl buttons (over 17,000,000 gross annually) from the shells of the mussels found in the neighbourhood, now supplemented by shipments from a wide area. Other important products are catsup, sauerkraut and preserves, dehydrated horse-radish, sash and doors, butter, automatic button machines, pressed steel pulleys, steel dies, canning machinery, packed meats and poultry, and air calliaphones. The aggregate factory output in 1925 was valued at $13,659,188. Muscatine was founded as a trading post in 1833, incorporated as a town ("Bloomington") in 1839, and chartered as a city under its present name in 1851.

MUSCICAPIDAE: *see* FLYCATCHER.

MUSCLE, STRUCTURE OF. Muscle is the tissue by which the various parts of the body are moved. Thus it forms the main bulk of the limbs, back, neck and body wall. Most of the viscera too possess well developed muscular coats. Muscle in all instances is built up of a number of long fibres. These are of three well defined types. Those forming the skeletal muscles are of large size, even in some instances up to 12cm. in length, their diameter varying from 0·01 to 0·1mm. Microscopically, these are characterized by a decided transverse marking, and they are therefore known as *striated muscle* fibres. From the fact that they comprise those muscles which are under the control of the will they are also called *voluntary muscle* fibres. The second variety of muscle is made up of much smaller fibres varying in different parts from 0·05 to 0·15mm. in length and about 0·005mm. in diameter. These fibres show no transverse striations nor are they directly under the control of the will. They are therefore termed *smooth* or *involuntary muscle.* Lastly, there is a third type of muscle found in the heart which lies intermediate in structure between these two varieties. In this the fibres are small and show distinct transverse striations. Longitudinal striations are also present though somewhat less marked. In most respects this form of muscle fibre resembles smooth muscle more closely than striated muscle.

Voluntary or Striated Muscle.—Each muscle fibre of which this is composed is a syncytium or plasmodium, *i.e.,* a structure containing a number of nuclei, which has been formed from a single cell by proliferation of its nucleus without subdivision of

the protoplasm. It is thus an assemblage of cells possessing a common protoplasm. Each fibre generally runs parallel to the length of the muscle and if this is short extends the whole length. Thus the one end of the fibre may be attached to tendon when the end is rounded off. The other end may also terminate in tendon or in the fibrous covering of bone in which case it is again rounded. In long muscles, however, the fibre may only extend a certain distance along the muscle, and it is then found to terminate in a tapering or bevelled end. In some of the long muscles some fibres may both arise and terminate in the substance of the muscles. In such a case both ends are bevelled. All the fibres in a muscle are arranged parallel to one another.

The outer surface of each muscle fibre consists of a tough homogeneous membrane called the *sarcolemma.* The main muscle substance is composed of several parts, viz., the *fibrillae,* the sarcoplasm and the nuclei. Under the action of reagents the muscle fibre may be split into a number of longitudinal elements. These are the fibrillae. They possess alternate bands of light and dark substance which give them a striated appearance. When viewed under polarized light the dark substance is found to be doubly refracting or anisotropic, the light band is singly refracting or isotropic. According to many observers, in the centre of each isotropic segment there is a thin transverse disc of anisotropic material and in the centre of each anisotropic segment a thin disc of isotropic substance. The fibrillae are arranged in the muscle fibre parallel to one another and with the alternate light and dark bands at approximately the same level across the fibre, thus giving to the whole muscle fibre its typical transverse striation. The fibrillae are united by interfibrillar substance to form bundles, of which there may be a considerable number in each muscle fibre. The bundles lie in a surrounding layer of sarcoplasm which apparently represents the remaining portion of unaltered protoplasm of the syncytium. This structure of muscle is best seen in the transverse sections of the fibres. A number of areas separated by a clear protoplasm are then to be seen. The areas are formed by the bundles of fibrillae seen in transverse section, the intermediate substance is the sarcoplasm. In some muscles, apparently, each fibrilla is surrounded by sarcoplasm, in which case the fibrillae are easily isolated from one another and can be readily examined. This is the case in the wing muscles of insects. The nuclei of the fibre are arranged close under the sarcolemma. Each is surrounded by a small quantity of sarcoplasm and in shape is an elongated ellipse. In most cases the muscle fibres do not branch, though in a few instances, such as the superficial muscles of the tongue, branching is found.

Involuntary or Smooth Muscle.—This particular form of muscle tissue when separated into its single constituents is seen to consist of fibres possessing a typical long spindle shape. The central part is somewhat swollen and contains an elongated nucleus centrally placed. The ends of the fibres are drawn out and pointed sharply. There is no definite surrounding membrane to each cell. In most of the cells, especially the larger, a distinct longitudinal marking can be seen. This is due to the presence of the fibrils which run the length of the fibre and are probably the essential contractile elements.

In most instances the cells are arranged to form bundles or sheets of contractile substance. In each bundle or sheet the cells are cemented to one another so that they may all act in unison. The cementing material is apparently membranous and is so arranged that contiguous fibres are only separated by a single layer of membrane. According to some, neighbouring fibres are connected to one another by minute offshoots, and these communications serve to explain the manner in which the contraction is observed to pass from fibre to fibre along a sheet composed of the muscles.

Involuntary muscle is the variety of muscle tissue found in the walls of the hollow viscera, such as the stomach, intestines, ureter, bladder, uterus, etc., and of the respiratory passages, in the middle coats of arteries, in the skin and the muscular trabeculae of the spleen. The arrangement is very typical, for instance, in the small intestine. Here the muscular coat consists of two layers of muscle. Each is in the form of a sheet which varies greatly in thickness in different animals. In the inner sheet the fibres, all parallel to one another, are disposed with their long axis transverse to the direction of the gut. In the outer layer, the direction of the fibres is at right angles to this. In a viscus with thick muscle walls the fibres are bound into bundles and the bundles may run in all directions. In some instances the bundles may form branching systems, thus constituting a network, notably in the bladder. In other instances, *e.g.,* the villi of the small intestine, the muscle fibres are separate, forming a felt-work with wide meshes.

Heart Muscle.—The fibres of which the muscular walls of the heart are composed though cross-striated are not voluntary. Each fibre is an oblongated cell possessing distinct transverse and less distinct longitudinal striations. There is no sarcolemma, and the nucleus of each fibre is placed in the centre. The longitudinal striation is due to the presence of fibrillae, each of which is cross striated. These lie parallel to one another in the cell, the sarcoplasm surrounding them being much more abundant in these fibres than in striated muscle. The fibrillae are arranged in rows, and when a transverse section of one of these fibres is examined it is seen that the rows radiate away from the centre of the cell. A further distinctive character of cardiac muscle fibres is that they frequently branch, the branches uniting with others from neighbouring cells. Moreover, the ends of the fibres are attached to corresponding faces of other cells, and through these attached faces the fibrillae pass, so that there is an approximation to the formation of a syncytium. (T. G. B.)

MUSCLE AND MUSCULAR EXERCISE. Muscle makes up a considerable, often a major fraction of the body, and many of the other functions are devoted to its service. It consists essentially of fibres, complete living units which are frequently of considerable length and about 0·05mm. in diameter. These fibres contain numerous minute fibrils embedded in the semi-liquid "sarcoplasm" inside the "sarcolemma." They are bound together by a connective tissue framework, and in the case of most voluntary muscles form anatomical units which are connected by tendons to the bony levers. Involuntary muscle, serving the "domestic" arrangements of the body (digestion, excretion, circulation, etc.), is usually in a sheet-like form, the fibres being mosaiced or cemented together to cover the organ operated. Cardiac muscle, intermediate between the other two types, consists of shorter fibres, apparently in direct physiological connection with one another, thus ensuring a co-ordinated response.

Animal movement is due to the shortening and thickening of these fibres, not to changes in their volume. This shortening is initiated, in the case of voluntary muscle, by an impulse from a nerve, but may be produced artificially by various means, chief of which is the electric shock. In cardiac muscle there is an inherent tendency to beat, and any piece of a heart, removed from contact with the rest, will proceed to shorten in its own intrinsic rhythm. In the normally functioning heart the speed is set by the quickest portion, viz., that near the entrance of the great veins, whence the beat is conducted rapidly from fibre to fibre so that the whole contracts approximately together. In involuntary muscle the fibres may show a rhythm of their own; more usually, like those of voluntary muscle, they require an impulse from a nerve; sometimes, as in the intestine, they possess also a primitive local nervous system co-ordinating their activity.

Voluntary muscle is richly supplied with blood vessels, bringing it fuel and oxygen. Even at rest the muscles require materials for combustion; they are the chief source of animal heat. If the resting heat production be insufficient, the animal either takes voluntary exercise or shivers, so increasing the output of heat from its muscles. At rest the majority of the blood capillaries are closed; during activity these open up and allow more blood to pass; this is supplied by the greater activity of the heart, and provided with oxygen by the enhanced efforts of the respiratory system.

The Mechanical Response.—The fundamental unit of muscular response is the twitch, contraction followed by relaxation. It is possible (though not certain) that in some muscles, *e.g.,* those holding closed the shells of bivalves, relaxation may not necessarily ensue; a semi-permanent change in length may occur on stimulation, the change requiring an expenditure of energy, but

the maintenance of the new length requiring none. In the vast majority of muscles, however, the unit of response involves relaxation as well as contraction, and a prolonged contraction can be maintained only by the fusion of a number of twitches in succession, so requiring a prolonged expenditure of energy. There are vast differences in the speed of the single twitch, which may occupy a few thousandths of a second in insects, and minutes, or even hours in some smooth muscles. A single twitch of given strength in a given length of muscle is associated always with a fairly constant liberation of total energy. If T dynes be the tension developed in the "isometric" twitch of a muscle fibre $l$cm. long, and if H ergs be the total energy set free (initial plus recovery) we have approximately, for all muscles, $\frac{H}{Tl}=\frac{1}{3}$. This relation is independent of the speed of response, so that in setting up a tension all muscles work similarly efficiently. In maintaining a tension for a given time, however, there are vast differences between muscles of different speed: those giving the quickest twitch require the highest frequency of stimulation to produce a properly fused summation, and expend correspondingly more energy. A muscle capable of giving a twitch in 0·003 second will liberate 20,000 times as much energy per second in maintaining a contraction as one whose twitch lasts for one minute. When, therefore, a force has to be maintained over long intervals a slow-moving muscle is essential. Ordinary voluntary movements are due to a fusion of twitches evoked by a rapid succession of impulses along the nerves.

The effect of a rise of temperature is to quicken the twitch and the rising phase of a tetanus. One effect of this quicker response is to make the maintenance of a contraction more expensive.

Much use has been made of the fact that muscles removed from the body may, under proper conditions, contract practically normally for many hours. The thinner the excised muscle the more satisfactory is its survival, since the usual provision of oxygen *via* the circulation must be replaced by diffusion from outside, which is a slow process over greater distances. It is common to immerse such muscles in "Ringer's fluid," a watery solution of salts in approximately the same concentrations as the blood.

The intrinsic strength of muscles is considerable. A frog's sartorius may exert a force of 2·5kilog. per sq.cm. of section, but this is small compared with the force of human muscles. In the human arm, for example, at a mechanical disadvantage of about 6:1, a force of 40 kilograms may be exerted at the hand by the biceps and brachialis muscles, with a cross-section of about 25sq.cms., which is about 10kilog. per square centimeter or approximately 10 atmospheres.

The "All-or-None" Principle.—It was shown by Keith Lucas that the twitch of a muscle fibre is independent of the strength of the impulse which evokes it, though dependent upon the condition of the fibre in its external and internal relations (temperature, length, preceding twitch, condition of fatigue, etc.). Strictly defined, this principle is universal and has the consequence that a muscular effort can be graduated in intensity only by adjusting the number of fibres employed in it, and not by adjusting the response of the individual fibres.

The Electric Response.—When a muscle fibre is excited a wave of negative potential, a few hundredths of a volt in magnitude and a few cms. in length, starts off in both directions from the stimulated point. The wave can be recorded, either in an excised muscle, or during voluntary movements in the body. This "electro-myogram" has been used very largely in investigations of the heart ("electrocardiogram") and considerably in studies of natural muscular movement. By means of it all voluntary and most reflex contractions have been shown to be of a discontinuous tetanic nature, due to a rapid succession of impulses reaching the muscle from the nerve; while a few reflex contractions, chiefly "tendon-jerks," have been found to be single twitches.

Tonic Contraction.—In the maintenance of body posture, and in preserving a readiness for instant action, a certain amount of muscle "tone" is necessary. When a muscle contracts, the tone of its antagonist is inhibited. It has been supposed that tone represents a different type of contraction, not of a tetanic nature, and it is reported that muscle fibres are doubly innervated, by voluntary and by sympathetic nerves; section of the sympathetic has been stated to cause a loss of tone. The evidence is not yet conclusive and there seems to be at present insufficient reason to regard tonic contraction as different, in principle, from ordinary tetanus; it is merely weaker, only a small fraction of the fibres being active at any given moment. Perhaps the fibres which are normally concerned with maintenance of tone are naturally slower than their fellows, and so more economical in maintaining a tension. Differences in speed in the different fibres of an individual muscle group are known to occur.

The Thermal Response.—When a muscle contracts it liberates heat. This can be measured directly by placing an isolated muscle on a thermopile connected to a sensitive galvanometer, when a rise of about 0·003° C. is found in a single twitch: or it can be studied by placing a complete animal in a calorimeter and causing it to work. "Myothermic" experiments have thrown much light on the internal mechanism of the muscle.

Fatigue.—When a muscle deprived of oxygen is given a succession of shocks it gradually weakens and finally ceases to respond. When a muscle with its circulation intact, or adequately supplied with oxygen, is similarly treated, its response diminishes at first, but finally reaches a "steady state," in which recovery balances breakdown. The first case corresponds to very violent exercise in man, where energy requirement is far in excess of possible oxygen supply; the second corresponds to steady work of moderate intensity where oxygen supply rapidly rises to meet energy requirement.

The Elastic Properties and Viscosity of Muscle.—A resting muscle possesses characteristic elastic properties, tension rising more than in proportion to extension. It shows also the phenomenon of "after-extension," continuing to lengthen (or shorten) for some time after being loaded (or released). An active muscle is different in its elastic properties, but shows a phenomenon analogous to the after-extension of resting muscle, viz., a "viscosity" which largely reduces, at high speeds of shortening, the amount of work which the muscle can perform. This viscosity, which is an essential factor in all muscles, greatest in those which move most slowly, acts in the sense of a "governor" or "automatic brake," preventing the animal from attaining speeds of movement sufficient to threaten the integrity of its structure.

The Chemistry of Muscle.—Muscle is about 75% water. Its fibres are imbedded in a connective tissue framework; protein forms their chief chemical constituent. Their contents are semi-fluid and can be squeezed out as "muscle plasma"; the residue, consisting chiefly of "sarcolemma," connective tissue and nuclei, contains keratin, mucin and nuclein. The ash of muscle forms 1% to 1·5% and consists chiefly of potassium and phosphates, with traces of calcium, magnesium, chlorine and iron. Of nitrogenous substances the most important is creatine: of non-nitrogenous bodies fat glycogen and lactic acid must be mentioned.

Lactic Acid and Glycogen in Muscle.—It has long been known that a muscle in fatigue or rigor becomes acid. The classical work of Fletcher and Hopkins (1907) placed the subject of lactic acid in muscle on an exact basis and established:—(i.) That lactic acid is formed during rest without oxygen, during activity or rigor, or after injury; (ii.) that its formation in an injured muscle can be delayed or prevented by sufficient oxygen; (iii.) that once formed it may disappear in the presence of oxygen.

These facts led to the work of A. V. Hill on heat-production during the recovery phase, by which it was shown that lactic acid formed during activity is not removed by oxidation but in some other way, presumably by resynthesis to a precursor. Meyerhof established glycogen (a carbohydrate $[C_6H_{12}O_6]_n$ discovered by Bernard in 1857) as this precursor, and it now seems clear that all, or nearly all, the energy exchanges of active muscle can be described as follows:—

A. Initial non-oxidative phase (yielding mechanical energy)

Glycogen—>unknown intermediary—>lactic acid—>K-lactate, the neutralization of the acid being effected by the alkali of the tissue itself:

B. Recovery oxidative phase (following activity and lasting

for 5 to 80 minutes).

K-lactate—>lactic acid—>intermediary—>glycogen, the energy for this endothermic reaction being derived, at any rate in the isolated muscle, from the oxidation of glycogen in amount about 22% of that restored from lactate.

This division of activity into two phases, (A) work without oxygen and (B) recovery with oxygen, is very important, and is found as a general phenomenon in living tissues. The rate of supply of oxygen *via* the circulation is necessarily limited, and this arrangement allows temporarily for much greater rates of expenditure of energy than would be possible were the muscle dependent on contemporary combustion. The mechanism is essentially that of an accumulator, a charge being stored and capable of release at a high rate for a time without oxidation, a recharge being necessary later, with the expenditure of energy derived from combustion of food material.

Fatigue appears to be due to the accumulation of lactic acid inside the muscle fibres, and further activity becomes impossible when its concentration reaches about 0·3%. Glycogen is necessary for activity.

Phosphates in Muscle.—The rôle of phosphates, although not yet clear, is obviously important. The total phosphorus in muscle varies widely but does not exceed 0·25%. Of this a certain variable fraction is combined with protein and fat-complexes, but probably plays no part in the chemical exchanges of activity. The remainder ("acid-soluble") has been studied under four heads:—A. Inorganic phosphate; B. Organic phosphate; i. rapidly hydrolysed by acid; ii. hydrolysed slowly by incubation of the muscle in alkali, but not rapidly by acid; iii. unaffected by treatment (i.) or (ii.).

(A) is small in resting muscle, but increases largely in fatigue and rigor; (B) (i.), which has often been mistaken for (A), is a compound of creatine and phosphate ("phosphagen"—Eggleton) which breaks down during stimulation and rigor, is restored in the presence of oxygen, but is not a source of lactic acid; (B) (ii.) is possibly a hexose-diphosphate; it breaks down during rigor, but may increase during activity; its usual connotation "lactacidogen" is quite unfortunate, since in activity at least it is not the immediate source of lactic acid. (B) (iii.) is probably a chemically stable hexose-monophosphate. These two hexose-phosphates have been isolated from muscle, the diphosphate being identical with that produced by yeast fermentation. Muscles are capable of synthesising hexosephosphates from glycogen and phosphoric acid. These phosphate compounds probably act as intermediaries in the breakdown of glycogen to lactic acid, the monophosphate perhaps being the immediate source of lactic acid in contraction.

There is a small but definite rise in blood phosphate following exercise; this, however, is not comparable in magnitude with that of blood lactic acid under similar conditions.

Muscular Exercise in Man.—Many of the factors described above are found in the case of muscular exercise in man. For example, muscle "viscosity" is very obvious in the case of movements made at high speed and explains the very exhausting nature of such exercise; while, together with the fact of energy expenditure during the maintenance of a contraction, it serves to determine an "optimum speed" for many types of movement. Recovery after exertion is well known, and its rate and extent can be measured by the amount of oxygen consumption which it occasions. Lactic acid is found in large quantities in the blood after exertion, and the "oxygen debt" allows its amount in the body as a whole to be calculated. Strong evidence has been found that in man glycogen is used preferentially as the immediate fuel of muscular exercise, as it is in laboratory experiments on isolated muscles. Recent applications indeed of academic muscle physiology have afforded an interesting and gratifying page in the history of applied science.

The Energy Exchanges of Exercise.—Various methods have been employed of measuring the energy liberated in the body, which of course all comes from the combustion of foodstuffs in the active tissues. A man has been placed in a calorimeter and his energy output determined directly; but, except for special purposes, this method is laborious and inadaptable. The most convenient procedure is to measure the oxygen consumption (O_2) and the carbon dioxide production (CO_2), which can be done by a collection, analysis and measurement of the air breathed out. Tables have been constructed from which, knowing the (O_2) and the (CO_2), the energy value of 1 litre of oxygen can be read off: or, in exercise of short duration, it is usually simpler and just as accurate to assume that 1 litre of oxygen corresponds to the following amount of energy (calculated for the combustion of glycogen). 1 litre of oxygen=5·14 calories=15,860 foot-pounds.

The oxygen consumption can be measured during exercise of all kinds, even running, skating, ski-ing and swimming.

The "Oxygen Income."—When exercise commences the oxygen consumption begins to rise, and in two or three minutes (sooner in some, later in other forms of exercise) it attains its full value. This gradual rise is occasioned, or accompanied, by several events:— (i.) the acceleration of the heart and the quickening of the circulation; (ii.) the deepening and quickening of respiration; (iii.) the gradual accumulation of lactic acid in tissues and blood.

When exercise ends the oxygen consumption begins to decrease, and in 5 to 80 minutes, depending on the violence and duration of the preceding exercise, it falls to its original value again. During this fall (i.) the heart and circulation return to their previous rate; (ii.) the respiration reverts to its resting condition; (iii.) the excess of lactic acid in the blood and tissues disappears.

During the exercise, if moderate, a "steady state" may be attained, the increasing rate of oxygen consumption leading to an increasing rate of lactic acid removal, until finally a balance is struck at levels of lactic acid concentration and of oxygen consumption which are characteristic of the exercise. If, however, the exercise be too intense no balance is possible, since there is a strict limit to the rate at which oxygen can be supplied to the muscle fibres, even with the most strenuous efforts of heart and lungs to cope with the situation. The rate of lactic acid formation is then never balanced by that of its removal, and fatigue and exhaustion gradually set in. Thus the limit of prolonged exertion is set by the "maximum oxygen income" of the body. This in athletic men of ordinary size is usually about 4 litres per minute, corresponding to a total energy liberation of about 63,400ft.lb. per minute. It is found that, under good conditions, the "mechanical efficiency" of a man at work, viz. (work done)÷(total energy used), may rise as high as 25%, so that, during prolonged work the greatest possible mechanical output of a man is about 15,860ft.lb. per minute, or just under ½ horse-power.

In less athletic individuals the maximum oxygen income is smaller and the upper limit of exertion lower; it is smaller also during exercise in which the body is held in a constrained position, or part only of it used. The rôle played by the heart in severe exercise should be noted. To distribute 4 litres of oxygen at least 30 litres of blood must be pumped round the body every minute; the whole of the blood must circulate six times.

Recovery from Exertion.—In the isolated muscle suspended in oxygen recovery from considerable exertion takes many hours, owing to the slowness of the oxygen supply by diffusion alone. In the intact animal at rest after exercise the supply of oxygen, except in the earliest moments of recovery, is more than adequate and recovery goes on at its own intrinsic rate, unaffected by considerations of oxygen supply. After moderate exertion recovery is quick—there has been no considerable accumulation of lactic acid, and the body returns rapidly to its resting state. The "oxygen debt" at the end of the exercise may be of the order of 1 or 2 litres but not more; and this is soon paid off. After harder exercise, however, in which the oxygen requirement has been considerably in excess of the maximum oxygen supply, there may be large quantities (up to 100gms. or more) of lactic acid in the tissues, and this will require large quantities of oxygen for its removal. The highest recorded value of the "oxygen debt" at the end of exercise is nearly 20 litres, but one of 15 litres is a very fair performance. It will be seen at once that this possibility of "running into debt" for a large quantity of the oxygen required has a considerable influence on the degree of strenuousness of the exercise which can be undertaken for a limited period. Without this "accumula-

1. Aeroplane view of Wilson dam, 4,300 ft. in length, in the Muscle Shoals section of the Tennessee river, Alabama

2. Wilson dam, seen from the south bank on the down stream side, showing construction work in progress

tor function" in muscle, no effort of any considerable severity could be made.

After violent exertion, recovery may take a considerable time, up to 80 minutes for the case when exercise was prolonged as well as strenuous. Even 100 yards run at top speed may require 50 minutes for complete recovery. Fitter individuals tend to have a higher recovery rate.

The Effect of Breathing High and Low Pressures of Oxygen.—During prolonged and strenuous exertion unpleasant subjective feelings may be much relieved by breathing oxygen instead of air, and measurement shows that under such conditions a considerable rise in the oxygen intake may take place. The blood, rushing at high speed through the lung capillaries, apparently does not collect its full quota of oxygen unless diffusion through the lung membranes is quickened up. Conversely, by low oxygen pressures the unpleasant subjective feelings may be aggravated and the rate of oxygen intake diminished. This is of great importance at high altitudes; no amount of "acclimatisation" will compensate completely for the lower pressure of oxygen in the lung alveoli. At high altitudes dyspnoea more rapidly sets in, the tendency to work by incurring an oxygen debt is more insistent, while at extreme heights the rests for recovery become more frequent since the oxygen income is so largely diminished. The administration of oxygen brings immediate relief, by quickening the passage of oxygen into the blood, as well as by supplying the brain and heart with oxygen at a higher partial pressure.

Muscular Training.—Very little physiological knowledge exists as to the nature of the changes that come over the body during muscular training. There are many possibilities: (1) Better muscular co-ordination, involving more economical and better directed movement; (2) an improvement in those chemical relationships of the tissues which determine the speed of recovery; (3) greater mechanical strength in the connective tissue of the muscles and in the sarcolemma of the fibres; (4) an increased oxygen carrying power of the blood; (5) a more complete capillary circulation, and a better lymph supply; (6) an increase in the alkali-reserve of the blood and muscle fibres, resulting in a greater lactic acid tolerance; (7) an increase in muscle glycogen, and possibly in the phosphate intermediaries of the lactic acid breakdown; (8) a more powerful heart beat, perhaps due to improvements in the coronary circulation.

The list might be extended considerably, but to little purpose. To illustrate the inadequacy of present knowledge the case of muscular stiffness may be cited. Some individuals readily become stiff, others do not. A fit and healthy man may be reduced to the extremity of stiffness by a few seconds of unaccustomed exercise: yet, on another occasion, having been "trained" by a few previous bouts of the same exertion, he is completely unaffected. This case is mentioned specifically because the layman, discussing muscular exercise with a physiologist, often tends to ask the cause of muscular stiffness, to which, at present, if he be honest, the physiologist must reply that he does not know.

MUSCLE SHOALS, a name given to a section of the Tennessee river, approximately 37 m. long, above Florence, Alabama. In this distance the river drops 132 ft. when it is discharging its average flow. The above section of the river is made up of rapids and connecting pools that collectively make navigation of the river in its natural state impossible. The first part of the name is probably the obsolete form of mussel, which is derived from Lat. *musculus,* dim. of *mus,* mouse.

The discharge of the Tennessee river in the Muscle Shoals section is produced by an average annual rainfall of about 45 in., falling on a catchment basin 30,800 sq.m. in area. The volume of water thus created, uninfluenced by artificial storage, has varied from 5,000 cu.ft. per second to a maximum of 500,000 cu.ft. In the earlier colonial days the Tennessee river was considered of sufficient importance by the Federal Government to receive more or less continuous engineering study from the time of George Washington down to 1918, when President Wilson ordered the building on Muscle Shoals, near Florence, of the structures shown in the Plate as a war and national defence measure.

As a result of the various navigation surveys and studies of Muscle Shoals, made between 1828 and 1889, a small and incomplete set of lateral canals and locks were completed in 1890 by the Federal Government. These locks and canals proved of practically no value because of the absence of sufficient tonnage either up or down the river. In 1907 the Federal Government ordered the chief of army engineers to make a new examination of Muscle Shoals for the purpose of ascertaining its navigation and hydro-electric power possibilities. As a result of these examinations and of succeeding official and private studies, sufficient engineering data of a reliable character had been assembled to warrant President Wilson in 1918 ordering the construction of what was then named dam No. 2 on the Tennessee river, as a part of the general plan prepared by the U.S. army engineers for the improvement of the entire Muscle Shoals stretch of the river. Actual construction of dam and power-house No. 2 was begun by the war department in April, 1918, as an emergency war measure, to aid in the supply of nitric acid for war needs in lieu of Chilean nitrate of soda. The termination of the war in 1918 found the plant only about 30% completed, and the question then arose as to whether to complete or abandon the power-plant and navigation work at Muscle Shoals. The plan to finish the structure prevailed, and the initial installation shown in the figure was placed in practical commission in Sept. 1925.

The entire length of dam and power-house is 4,300 ft., divided by expansion joints into 90 sections. Field measurements showed that the aggregate of the temperature and other changes in the lengths of these 90 sections was over 9 inches. The masonry crest of the dam is surmounted by flood gates, by the operation of which a uniform pool level can be maintained above the dam independent of the quantity of water flowing through the pool, and independent of the amount of water used for power purposes. The capacity of the flood gates is any discharge up to a maximum of one million cu.ft. per second, or three times the maximum discharge of the St. Lawrence river in the International section.

When the economically feasible storage basins officially planned for the valley of the Tennessee river above dam No. 2 are in commission, the Tennessee river as a whole will add 3,000,000 hydro-electric horse-power to the industrial resources of over twelve million people in seven Southern States. Dam No. 2 at Florence, Ala., will be the major unit upon which will be founded a superpower system of great value to the South. (H. Co.)

MUSCOVITE, a rock-forming mineral belonging to the mica group (*see* MICA). It is also known as potash-mica, being a potassium, hydrogen and aluminium orthosilicate, $H_2KAl_3(SiO_4)_3$. As the common white mica obtainable in thin, transparent cleavage sheets of large size it was formerly used in Russia for window panes and known as "Muscovy glass"; hence its name. It crystallizes in the monoclinic system; distinctly developed crystals, however, are rare and have the form of rough six-sided prisms or plates; thin scales without definite crystal outlines are more common. The most prominent feature is the perfect cleavage parallel to the basal plane, on which the lustre is pearly in character. The hardness is 2–2½, and the specific gravity 2·8–2·9.

Muscovite frequently occurs as fine scaly to almost compact aggregates, especially when, as is often the case, it has resulted by the alteration of some other mineral, such as felspar, topaz, kyanite, etc. Varieties depending both on differences in structure and in chemical composition have been distinguished. Scaly varieties are damourite, gilbertite, sericite (Gr. σηρικός, silky), etc. In sericite the fine scales are united in fibrous aggregates

giving rise to a silky lustre: this variety is a common constituent of phyllites and sericite-schists. Several compact minerals, included together under the name pinite, have resulted by the alteration of cordierite, spodumene and other minerals. Fuchsite or "chrome-mica," is a bright green variety containing chromium.

Muscovite is of wide distribution and is the commonest of the micas. In igneous rocks it is found only in granite, never in volcanic rocks; but it is abundant in gneiss and mica-schist, and in phyllites and clay-slates, where it has been formed at the expense of alkali-felspar by dynamo-metamorphic processes. In pegmatite-veins traversing granite, gneiss or mica-schist it occurs as large sheets of commercial value, and is mined in India, East Africa, the United States and Brazil.

MUSCULAR SYSTEM, ANATOMY OF (*see* also MUSCLE, STRUCTURE OF). Here only the voluntary muscles, under the control of the will, are considered.

The voluntary muscles form the red flesh of an animal, and are the structures by which one part of the body is moved at will upon another. Each muscle is said to have an origin and an insertion, the former being that attachment which is usually more fixed, the latter that which is more movable. This distinction, though convenient, is arbitrary, as an example will show. The *pectoralis major* being attached to the front of the chest and to the upper part of the arm bone its contraction draws the arm towards the chest, whereas, when, in climbing a tree, the hand grasps a branch above, contraction will draw the chest towards the arm. Generally, a muscle is partly fleshy and partly tendinous; the fleshy contractile part is attached at one or both ends to cords or sheets of white fibrous tissue, which in some cases pass round pullies and so change the direction of the muscle's action. The other end of these cords or *tendons* is usually attached to the periosteum of bones, with which it blends. In some cases, when a tendon passes round a bony pulley, a sesamoid bone is developed in it which diminishes the effects of friction. A good example of this is the patella in the tendon of the *rectus femoris* (fig. 1).

Every muscle is supplied with blood vessels and lymphatics (fig. 1), and with one or more nerves. The nerve supply is very important both from a medical and a morphological point of view. The attachments are also important, as determining the action of the muscle. This action cannot be understood by reference to the dead body alone, for every movement expresses the balanced contractions of numerous muscles. (*See* C. E. Beevor, *Croonian Lectures for 1903,* London, 1904.)

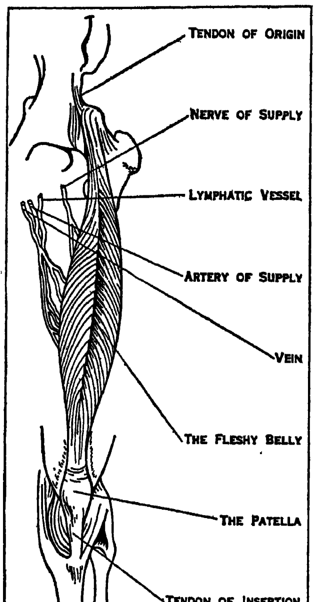

FIG. 1.—THE RECTUS MUSCLE OF THE THIGH, SHOWING THE CONSTITUENT PARTS OF A MUSCLE

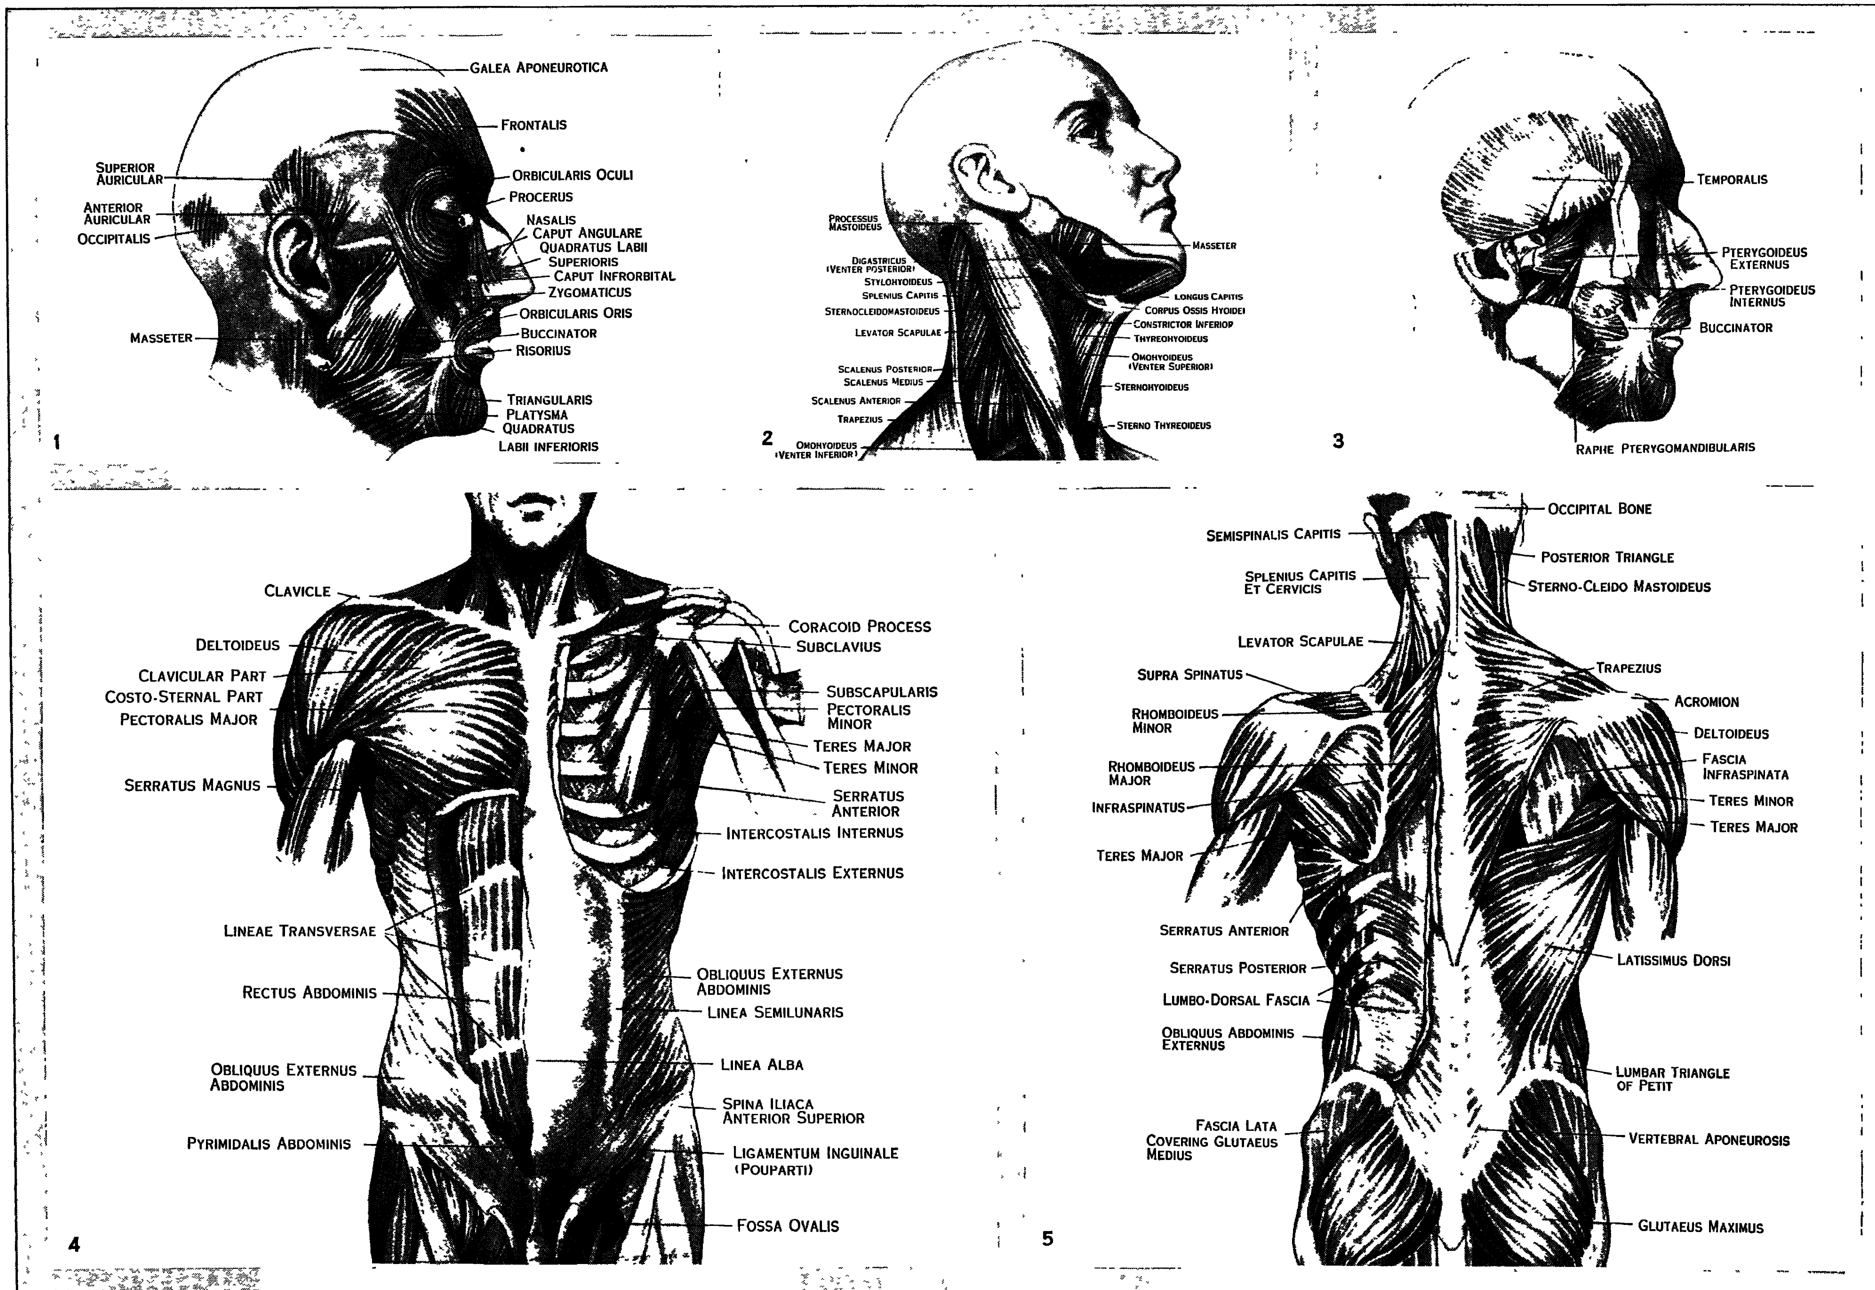
Muscles may be fusiform, as in fig. 1, conical, riband-like, or flattened into triangular or quadrilateral sheets. They may also be attached to skin, cartilage or fascia instead of to bone, while certain muscles surround openings which they constrict and are called *sphincters.* The names of the muscles have gradually grown up, and no settled plan has been used in giving them. The German anatomists at the Basle conference lately proposed a uniform Latin and Greek nomenclature, which, though not altogether satisfactory, is gaining ground on the European continent. As there are some four hundred muscles on each side of the body it will be impossible here to attempt more than a mere sketch; for the details the anatomical textbooks must be consulted.

Muscles of the Head and Face (Pl. I.–1).—The scalp is moved by a large flat muscle called the *occipito-frontalis,* which has two muscular bellies, the *occipitalis* and *frontalis,* and an intervening *epicranial aponeurosis;* this muscle moves the scalp and causes the transverse wrinkles in the forehead. The *anterior, posterior* and *superior auricular muscles* are present but are almost functionless in man. The *orbicularis palpebrarum* forms a sphincter round the eyelids, which it closes, though there is little doubt that parts of the muscle can act separately and cause various expressions. The side of the nose has several muscles, the actions of which are indicated by their names; they are the *compressor,* two *dilatores* and the *depressor alae nasi,* while the *levator labii superioris et alae nasi* sometimes goes to the nose. Raising the upper lip, in addition to the last named, are the *levator labii superioris proprius* and the *levator anguli oris,* while the *zygomaticus major* draws the angle of the mouth outward. The lower lip is depressed by the *depressor labii inferioris* and *depressor anguli oris,* while the *orbicularis oris* acts as a sphincter to the mouth. The *buccinator muscle* in the substance of the cheeks rises from the upper and lower jaws and runs forward to blend with the *orbicularis oris.* All the foregoing are known as muscles of expression and all are supplied by the seventh or facial nerve. The *temporal muscle* at the side of the cranium (Pl. I.–3) and the *masseter* (Pl. I.–2), which rises from the zygoma, close the mouth, since both are inserted into the ramus of the mandible; while, rising from the pterygoid plates, are the *external* and *internal pterygoid muscles* (Pl. I.–3), the former of which pulls forward the condyle, and so the whole mandible, while the latter helps to close the mouth by acting on the angle of the lower jaw. This group of muscles forms the masticatory set, all of which are supplied by the third division of the fifth nerve. For the muscles of the orbit, *see* EYE; for those of the soft palate and pharynx, *see* PHARYNX; and for those of the tongue, *see* TONGUE.

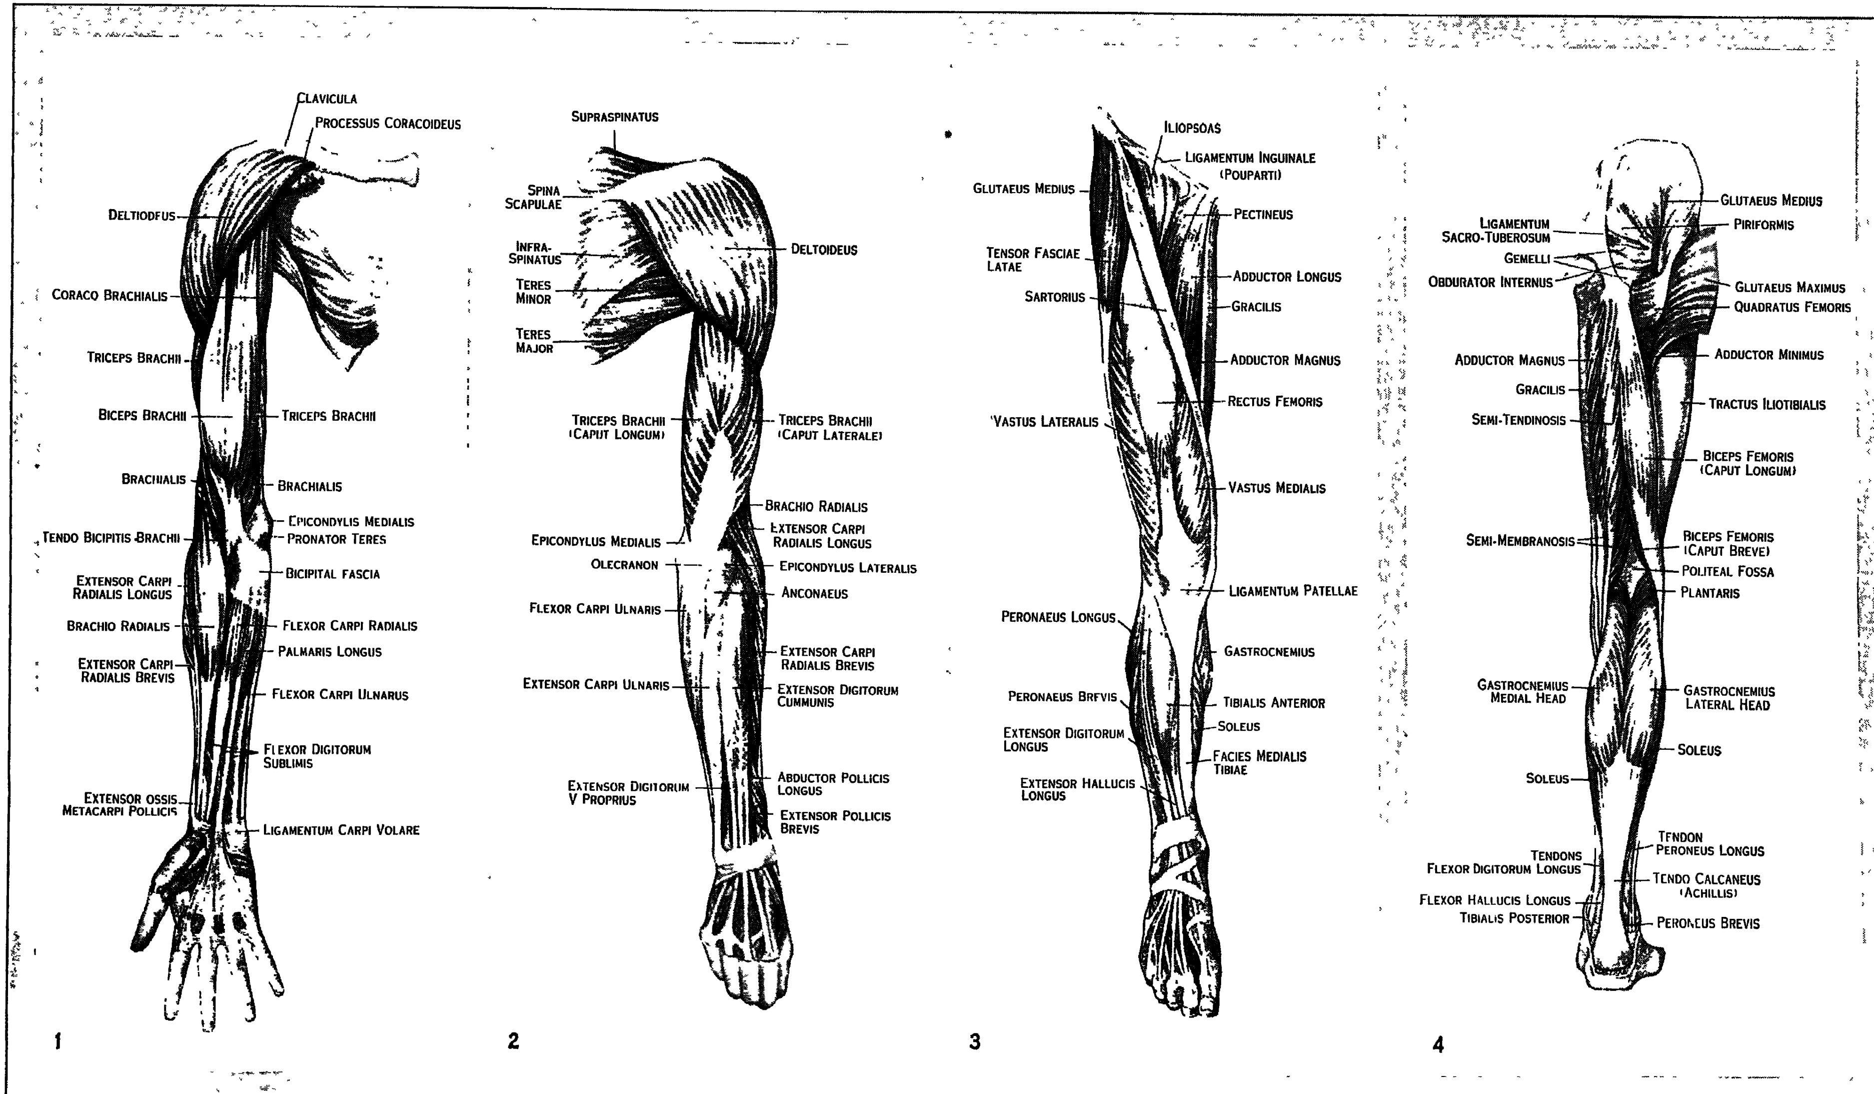
Muscles of the Neck (Pl. I.–2).—Just below the mandible is the *digastric,* which, as its name shows, has two bellies and a central tendon; the anterior belly, supplied by the fifth nerve, is attached to the mandible near the symphysis, the posterior supplied by the seventh of the mastoid process, while the central tendon is bound to the hyoid bone. Stretching across from one side of the lower jaw to the other and forming a floor to the mouth is the *mylo-hyoid muscle;* posteriorly this reaches the hyoid bone, and in the mid-line has a tendinous raphe separating the two halves of the muscle. Rising from the manubrium sterni and inner part of the clavicle is the *sterno-cleido-mastoid,* which is inserted into the mastoid process and superior curved lines of the occipital bone; when it contracts it makes the face look over the opposite shoulder, and it is supplied by the spinal accessory nerve as well as by branches from the cervical plexus. It is an important surgical landmark, and forms a diagonal across the quadrilateral outline of the side of the neck, dividing it into an anterior triangle with its apex downward and a posterior with its apex upward. In the anterior triangle the relative positions of the hyoid bone, thyroid cartilage and sternum should be realized, and then the *hyo-glossus, thyro-hyoid, sterno-hyoid* and *sterno-thyroid* muscles are explained by their names. The *omo-hyoid* muscle rises from the upper border of the scapula and runs across both triangles to the hyoid bone. Where it passes deep to the sterno-mastoid it has a central tendon which is bound to the first rib by a loop of cervical fascia. Rising from the styloid process are three muscles, the *stylo-glossus, stylo-hyoid* and *stylo-pharyngeus,* the names of which indicate their attachments. Covering these muscles of the anterior triangle is a thin sheet, close to the skin, called the platysma, the upper fibres of which run back from the mouth over the cheek and are named the *risorius* (Pl. I.–1); this sheet is one of the few remnants in man of the skin musculature or *panniculus carnosus* of lower mammals. With regard to the nerve supply of the anterior triangle muscles, all those which go to the tongue are supplied by the hypoglossal or twelfth cranial nerve, while the muscles below the hyoid bone are apparently supplied from this nerve but really from the upper cervical nerves (*see* NERVE, CRANIAL; and NERVE, SPINAL). The posterior triangle is formed by the *sterno-mastoid* in front, the *trapezius* behind, and the clavicle below; in its floor from above downward part of the following muscles are seen: *complexus, splenius, levator anguli scapulae, scalenus medius* and *scalenus anticus.* Sometimes a small piece of the *scalenus posticus*



MUSCULAR CONSTRUCTION OF HEAD, NECK AND TRUNK

1. Muscles of the face and scalp (muscles of expression)
2. The triangles of the neck
3. Pterygoid region (base of skull)
4. Anterior muscles of the trunk
5. Posterior muscles of the trunk

MUSCULAR SYSTEM



MUSCULAR CONSTRUCTION OF THE ARMS AND LEGS

1. Muscles of the arm and forearm (front)
2. Muscles of the arm and forearm (back)
3. Muscles of the thigh and leg (front)
4. Muscles of the thigh and leg (back)

is caught sight of behind the scalenus medius. The splenius rotates the head to its own side, the levator anguli scapulae raises the upper angle of the scapula, while the three scalenes run from the transverse processes of the cervical vertebrae and fix or raise the upper ribs. The trapezius (Pl. I.–5) arises from the spines of the thoracic vertebrae and the ligamentum nuchae, and is inserted into the outer third of the clavicle and the spine of the scapula; it is used in shrugging the shoulders and in drawing the upper part of the scapula toward the mid-dorsal line. Its nerve supply is the spinal accessory and third and fourth cervical nerves. When the superficial muscles and complexus are removed from the back of the neck, the *sub-occipital* triangle is seen beneath the occipital bone. Externally it is bounded by the *superior oblique,* running from the transverse process of the atlas to the lateral part of the occipital bone, internally by the *rectus capitis posticus major,* passing from the spine of the axis to the lateral part of the occipital bone, and inferiorly by the *inferior oblique* joining the spine of the axis to the transverse process of the atlas. These muscles move the head on the atlas and the atlas on the axis. They are supplied by the posterior branch of the first cervical nerve.

Muscles of the Trunk.—The trapezius has already been described as a superficial muscle of the upper part of the back; in the loin region the *latissimus dorsi* (Pl. I.–5) is the superficial muscle, its origin being from the lower thoracic spines, lower ribs and lumbar fascia, and it is inserted into the upper part of the arm bone. When the trapezius is cut, the *rhomboid muscles* (major and minor) passing from the upper thoracic spines to the vertebral border of the scapula are seen, and deep to these is the *serratus posticus superior* passing from nearly the same spines to the upper ribs. On reflecting the latissimus dorsi the *serratus posticus inferior* is seen running from the lower thoracic spines to the lower ribs. When these muscles are removed the great mass of the *erector spinae* is exposed, familiar to every one as the upper cut of the sirloin or ribs of beef; it runs all the way up the dorsal side of the vertebral column from the pelvis to the occiput, the complexus already mentioned being its extension to the head. It is longitudinally segmented into many different bundles to which special names are given, and it is attached to the various vertebrae and ribs as it goes up, thus straightening the spinal column. Deep to the erector spinae are found shorter bundles passing from one vertebra to another and forming the *semispinalis* and *multifidus spinae* muscles. The latissimus dorsi and rhomboids are supplied by branches of the brachial plexus of nerves, while the deeper muscles get their nerves from the posterior primary divisions of the spinal nerves (*see* NERVE, SPINAL). On the anterior part of the thoracic region the *pectoralis major* runs from the clavicle, sternum and ribs, to the humerus (Pl. I.–4); deep to this is the *pectoralis minor,* passing from the upper ribs to the coracoid process. The *serratus magnus* is a large muscle rising by serrations from the upper eight ribs, and running back to the vertebral border of the scapula, which it draws forward as in the fencer's lunge. Between the ribs are the *external* and *internal intercostal* muscles; the former beginning at the tubercle and ending at the junctions of the ribs with their cartilages, while the latter only begin at the angle of the ribs but are prolonged on to the sternum, so that an interchondral as well as an intercostal part of each muscle is recognized. The fibres of the external intercostals run downward and forward, those of the internal downward and backward (*see* RESPIRATION). The abdominal walls are formed of three sheets of muscle, of which the most superficial or *external oblique* (Pl. I.–4) is attached to the outer surfaces of the lower ribs; its fibres run downward and forward to the pelvis and mid-line of the abdomen, the middle one or *internal oblique* is on the same plane as the ribs, and its fibres run downward and backward, while the *transversalis* is attached to the deep surfaces of the ribs, and its fibres run horizontally forward. Below, all these muscles are attached to the crest of the ilium and to Poupart's ligament, which is really the lower free edge of the external oblique, while, behind, the two deeper ones, at all events, blend with the fascia lumborum. As they approach the mid-ventral line they become aponeurotic and form the *sheath of the rectus.* The *rectus abdominis* (Pl. I.–4) is a flat muscular band which runs up on each side of the linea alba or mid-ventral line of the abdomen from the pubis to the ribs and sternum. This muscle has certain tendinous intersections or *lineae transversae,* the positions of which are noticed in the article ANATOMY (*Superficial and Artistic*), and the morphology of which is referred to later. In front of the lowest part of the rectus is sometimes a small triangular muscle called the *pyramidalis.* The *quadratus lumborum* is a muscle at the back of the abdominal wall which runs between the last rib and the crest of the ilium. In front of the bodies of the vertebrae is a prevertebral or hypaxial musculature, of which the *rectus capitis anticus major* and *minor* muscles and *longus colli* in the neck and the *psoas* in the loins form the chief parts, the latter being familiar as the undercut of the sirloin of beef, while the pelvis is closed below by a muscular floor formed by the *levator ani* and *coccygeus* muscles. The diaphragm is explained in a separate article.

Muscles of the Upper Extremity.—The *deltoid* (see Pl. I.–4 and 5) is the muscle which forms the shoulder cap and is used in abducting the arm to a right angle with the trunk; it runs from the clavicle, acromial process and spine of the scapula, to the middle of the humerus, and is supplied by the circumflex nerve. Several short rotating muscles pass from the scapula to the upper end of the humerus; these are the *subscapularis* passing in front of the shoulder joint, the *supraspinatus* above the joint, and the *infraspinatus* and *teres minor* behind. The *teres major* (Pl. I.–4 and 5) comes from near the lower angle of the scapula, and is inserted with the latissimus dorsi into the front of the surgical neck of the humerus. The *coracobrachialis* (Pl. II.–1) passes from the coracoid process to the middle of the humerus in front of the shoulder joint, while the *brachialis anticus* passes in front of the elbow from the humerus to the coronoid process of the ulna. Passing in front of both shoulder and elbow is the *biceps* (Pl. II.–1), the long head of which rises from the top of the glenoid cavity inside the joint, while the short head comes from the coracoid process. The insertion is into the tubercle of the radius. These three muscles are all supplied by the same (musculo-cutaneous) nerve. At the back of the arm is the *triceps* (Pl. II.–2) which passes behind both shoulder and elbow joints and is the great extensor muscle of them; its long head rises from just below the glenoid cavity of the scapula, while the inner and outer heads come from the back of the humerus. It is inserted into the olecranon process of the ulna and is supplied by the musculo-spinal nerve. The muscles of the front of the forearm form superficial and deep sets (Pl. II.–1). Most of the superficial muscles come from the internal condyle of the humerus. From without inward they are the *pronator radii teres* going to the radius, the *flexor carpi radialis* to the base of the index metacarpal bone, the *palmaris longus* to the palmar fascia, the *flexor sublimis digitorum* to the middle phalanges of the fingers, and the *flexor carpi ulnaris* to the pisiform bone. The important points of practical interest about these muscles are noticed in the article ANATOMY (*Superficial and Artistic*). In addition to these the brachio-radialis is a flexor of the forearm, though it arises from the outer supracondylar ridge of the humerus. It is supplied by the musculo-spiral nerve, the flexor carpi ulnaris by the ulnar, the rest by the median. The deep muscles of the front of the forearm consist of the *flexor longus pollicis* running from the radius to the terminal phalanx of the thumb, the *flexor profundus digitorum* from the ulna to the terminal phalanges of the fingers, and the *pronator quadratus* passing across from the lower third of the ulna to the same amount of the radius. These three muscles are supplied by the anterior interosseous branch of the median nerve, but the flexor profundus digitorum has an extra twig from the ulnar. The extensor muscles at the back of the forearm are also divided into superficial and deep sets (see Pl. II.–2). The former rise from the region of the external condyle of the humerus, and consist of the *extensor carpi radialis longior* and *brevior* inserted into the index and medius metacarpal bones, the *extensor communis digitorum* to the middle and distal phalanges of the fingers, the *extensor minimi digiti,* the *extensor carpi ulnaris* passing to the metatarsal bone of the minimus, and the *supinator brevis* wrapping round the neck of the radius to which it is inserted. The *aconeus* which runs from the external condyle to the olecranon process is really a part of the triceps. The deep mus-

cles rise from the posterior surfaces of the radius and ulna, and are the *extensor ossis metacarpi pollicis,* the name of which gives its insertion, the *extensor brevis pollicis* to the proximal phalanx, and the *extensor longus pollicis* to the distal phalanx of the thumb, while the *extensor indicis* joins the extensor communis slip to the index finger; all these posterior muscles are supplied by the posterior interosseous nerve. In front and behind the wrist the tendons are bound down by the anterior and posterior annular ligaments, while on the flexor surface of each finger is a strong fibrous sheath or *theca* for the flexor tendons. The ball of the thumb is occupied by short muscles called the *thenar* group, while *hypothenar* muscles are found in the ball of the little finger. The four *lumbrical* muscles (fig. 2) run from the flexor profundus digitorum tendons to those of the extensor communis between the heads of the metacarpal bones while, rising from the shafts of these bones, are the three *palmar* and four *dorsal interosseous* muscles (fig. 2) which also are inserted into the extensor tendons. The two outer lumbricals and the *thenar* muscles are supplied by the median nerve; all the other hand muscles by the ulnar.

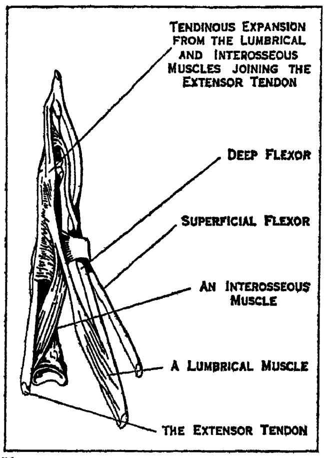


FIG. 2.—FIGURE SHOWING TENDONS ATTACHED TO A FINGER

Muscles of the Lower Extremity.—On the front of the thigh the *quadriceps extensor* muscles are the most important: there are four of these, the *rectus femoris* (fig. 1) with its straight and reflected heads rising from just above the acetabulum, the *crureus,* deep to this, from the front of the femur, and the *vastus externus* and *internus* wrapping round the femur on each side from the linea aspera. All these are inserted into the patella, or rather the patella is a sesamoid bone developed where their common tendon passes round the lower end of the femur when the knee is bent. The distal part of this tendon, which passes from the patella to the tubercle of the tibia, is the *ligamentum patellae.* The *sartorius* is a long riband-like muscle running from the anterior superior spine of the ilium to the inner surface of the tibia, obliquely across the front of the thigh. It forms the outer boundary of *Scarpa's triangle,* the inner limit of which is the adductor longus and the base Poupart's ligament. The floor is formed by the *iliacus* from the iliac fossa of the pelvis, which joins the psoas, to be inserted with it into the lesser trochanter, and by the *pectineus* running from the upper ramus of the pubis to just below the insertion of the last muscles. The *adductor* muscles, *longus, brevis* and *magnus,* all rise from the subpubic arch, and are inserted into the linea aspera of the femur, so that they draw the femur toward the middle line. The *gracilis* (Pl. II.–3) is part of the adductor mass, though its insertion is into the upper part of the tibia. The extensor muscles of the front of the thigh are supplied by the anterior crural nerve, but the adductor group on the inner side from the obturator. The pectineus is often supplied from both sources. On the back of the thigh the *gluteus maximus* (Pl. I.–5 and Pl. II.–4) plays a great part in determining man's outline (*see* ANATOMY: *Superficial and Artistic*). It rises from the sacral region, and is inserted into the upper part of the femur and the deep fascia of the thigh, which is very thick and is known as the *fascia lata;* the muscle is a great extensor of the hip and raises the body from the stooping position. The *gluteus medius* rises from the ilium, above the hip joint, and passes to the great trochanter; it abducts the hip and enables the body to be balanced on one leg, as in taking a step forward. The *gluteus minimus* is covered by the last muscle, and passes from the ilium to the front of the great trochanter, thus rotating the hip joint inward. Some of its anterior fibres are sometimes separate from the rest, and are then called the *scansorius.* When the gluteus maximus is removed, a number of short externally rotating muscles are seen, rising from the pelvis and inserted into the great trochanter (Pl. II.–4); these are, from above downward, the *piriformis, gemellus superior, obturator internus, gemellus inferior* and *quadratus femoris.* They are all supplied by special branches of the sacral plexus. On cutting the quadratus femoris a good deal of the *obturator externus* can be seen, coming from the outer surface of the obturator membrane and passing to the digital fossa of the great trochanter. Unlike the rest of this group, it is supplied by the obturator nerve. Coming from the anterior part of the crest of the ilium is the *tensor fasciae femoris,* which is inserted into the fascia lata, as is part of the gluteus maximus, and the thickened band of fascia which runs down the outer side of the thigh from these to the head of the tibia is known as the *ilio tibial band.* The tensor fasciae femoris, gluteus medius and minimus, are supplied by the superior gluteal nerve, the gluteus maximus by the inferior gluteal. At the back of the thigh are the *hamstrings* rising from the tuberosity of the ischium (Pl. II.–4); these are the *semimembranosus* and *semitendinosus,* passing to the inner part of the upper end of the tibia and forming the internal hamstrings, and the *biceps femoris* or external hamstring, which has an extra head from the shaft of the femur and is inserted into the head of the fibula. These muscles are supplied by the great sciatic nerve and extend the hip joint while they flex the knee. In the leg, as distinguished from the thigh, are three groups of muscles, anterior, external and posterior. The anterior group (Pl. II.–3) all come from the front of the tibia and fibula, and consist of the *extensor longus digitorum,* extending the middle and distal phalanges of the four outer toes, the *extensor proprius hallucis,* extending the big toe, and the *peroneus tertius,* a purely human muscle inserted into the base of the fifth metatarsal bone. All these are supplied by the anterior tibial nerve.

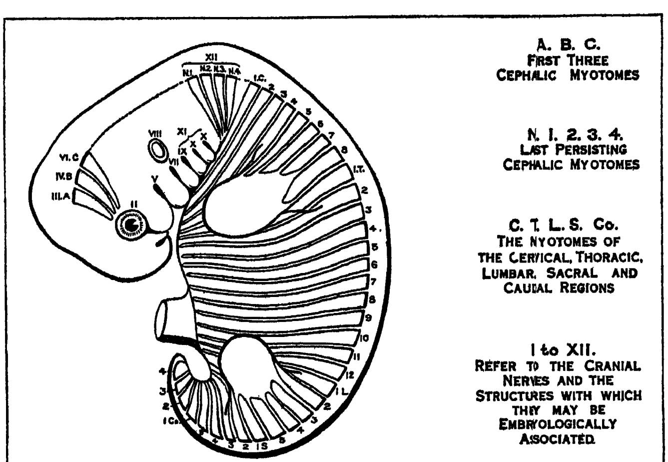
The external group comprises the *peroneus longus* and *brevis,* rising from the outer surface of the fibula and inserted into the tarsus (Pl. II.–3), the longus tendon passing across the sole to the base of the first metatarsal bone, the brevis to the base of the fifth metatarsal. These are supplied by the musculo-cutaneous nerve.

The posterior group is divided into a superficial and a deep set. The superficial is composed of the *gastrocnemius,* the two heads of which rise from the two condyles of the femur, the *soleus,* which rises from the upper parts of the back of the tibia and fibula, the *plantaris,* which comes from just above the external condyle of the femur, and the *popliteus* which, although on a deeper plane, really belongs to this group and rises by a tendon from the outer condyle while its fleshy part is inserted into the upper part of the back of the tibia. The gastrocnemius and soleus unite to form the *tendo Achillis,* which is attached to the posterior part of the calcaneum, while the plantaris runs separately as a very thin tendon to the same place. These muscles are supplied by the internal popliteal nerve. The deep set is formed by three muscles which rise from the posterior surfaces of the tibia and fibula, the *flexor longus digitorum,* the *tibialis posticus,* and the *flexor longus hallucis* from within outward. Their tendons all pass into the sole, that of the flexor longus digitorum being inserted into the terminal phalanges of the four outer toes, the flexor longus hallucis into the terminal phalanx of the big toe, while the tibialis posticus sends expansions to most of the tarsal bones. The nerve supply of this group is the posterior tibial. On the dorsum of the foot is the *extensor brevis digitorum,* which helps to extend the four inner toes, while in the sole are four layers of short muscles, the most superficial of which consists of the *adductor hallucis,* the *flexor brevis digitorum,* and the *adductor minimi digiti,* the names of which indicate their attachments. The second layer is formed by muscles which are attached to the flexor longus digitorum tendon; they are the *accessorius,* running forward to the tendon from the lower surface of the calcaneum, and the four *lumbricales,* which rise from the tendon after it has split for the four toes and pass between the toes to be inserted into the tendons of the extensor longus digitorum on the dorsum. The third layer comprises the *flexor brevis hallucis, adductor obliquus* and *adductor transversus hallucis* and the *flexor brevis minimi digiti.* The fourth layer contains the three *plantar* and four *dorsal interosseous muscles,* rising from the metatarsal bones and inserted into the proximal phalanges and extensor tendons in such a way that the plantar muscles

draw the toes towards the line of the second toe while the dorsal draw them away from that line. Of these sole muscles the flexor brevis digitorum, flexor brevis hallucis, adductor hallucis and the innermost lumbrical are supplied by the internal plantar nerve, while all the rest are supplied by the external plantar.

EMBRYOLOGY

The development of the muscular system is partly known from the results of direct observation, and partly inferred from the study of the part of the nervous system whence the innervation is derived. The unstriped muscle is formed from the mesenchyme cells of the somatic and splanchnic layers of the mesoderm (*see* VERTEBRATE EMBRYOLOGY), but never, as far as we know, from the mesodermal somites. The heart muscle is also developed from mesenchymal cells, though the changes producing its feebly striped fibres are more complicated. The skeletal or real striped muscles are derived either from the mesodermic somites or from the branchial arches. As the mesodermal somites are placed on each side of the neural canal in the early embryo, it is obvious that the greater part of the trunk musculature spreads gradually round the body from the dorsal to the ventral side and consists of a series of plates called *myotomes* (fig. 3). The muscle fibres in these plates run in the long axis of the embryo, and are at first separated from those of the two neighbouring plates by thin fibrous intervals called *myocommata*. In some cases these myocommata persist and even become ossified, as in the ribs, but more usually they disappear early, and the myotomes then unite with one another to form a great muscular sheet. In the whole length of the trunk a longitudinal cleavage at right angles to the surface occurs, splitting the musculature into a dorsal and ventral part, supplied respectively by the dorsal and ventral primary divisions of the spinal nerves. From the dorsal part the various muscles of the erector spinae series are derived by further longitudinal cleavages either tangential or at right angles to the surface, while the ventral part is again longitudinally split into mesial and lateral portions. A transverse section of the trunk at this stage, therefore, would show the cut ends of three longitudinal strips of muscle: (1) a mesial ventral, from which the rectus, pyramidalis sterno-hyoid, omo-hyoid and sterno-thyroid muscles are derived; (2) a lateral ventral, forming the flat muscles of the abdomen,



FROM A. M. PATTERSON, "CUNNINGHAM'S TEXTBOOK OF ANATOMY" (OXFORD MEDICAL PUBLICATIONS)

FIG. 3.—SCHEME ILLUSTRATING THE DISPOSITION OF MYOTOMES IN THE EMBRYO IN RELATION TO THE HEAD, TRUNK AND LIMBS

intercostals and part of the sternomastoid and trapezius; and (3) the dorsal portion already noticed. The mesial ventral part is remarkable for the persistence of remnants of myocommata in it, forming the linae transversae of the rectus and the central tendon of the omo-hyoid. The lateral part in the abdominal region splits tangentially into three layers, the external and internal oblique and the transversalis, the fibres of which become differently directed. In the thoracic region the intercostals probably indicate a further tangential splitting of the middle or internal oblique layer, because the external oblique is continued headward superficially to the ribs and the transversalis deeply to them. The more cephalic part of the external oblique layer probably disappears by a process of pressure or crowding out owing to the encroachment of the serratus magnus, a muscle which, as its nerve supply indicates, is derived from the lower cervical myotomes. The deeper parts of the lateral mass of muscles spread to the ventral surface of the bodies of the vertebrae, and form the *hypaxial muscles*—such as the psoas, longus colli and recti capitis antici. The nerve supply indicates that the lowest myotomes taking part in the formation of the abdominal walls are those supplied by the first and second lumbar nerves, and are represented by the cremaster muscle in the scrotum. In the perineum, however, the third and fourth sacral myotomes are represented, and these muscles are differentiated largely from the primitive sphincter which surrounds the cloacal orifice, though partly from vestigial tail muscles. In the head no distinct myotomes have been demonstrated in the mammalian embryo, but as they are present in more lowly vertebrates, it is probable that their development has been slurred over, a process often found in the embryology of the higher forms. Probably nine cephalic myotomes originally existed, of which the first gives rise to the eye muscle supplied by the third nerve, the second to the superior oblique muscle supplied by the fourth nerve, and the third to the external rectus supplied by the sixth nerve. The fourth, fifth and sixth myotomes are suppressed, but the seventh, eighth and ninth possibly form the muscles of the tongue supplied by the twelfth cranial nerve.

Turning now to the branchial arches, the first branchiomere is innervated by the fifth cranial nerve, and to it belong the masseter, temporal, pterygoids, anterior belly of the digastric, mylo-hyoid, tensor tympani and tensor palati, while from the second branchiomere, supplied by the seventh or facial nerve, all the facial muscles of expression and the stylo-hyoid and posterior belly of the digastric are derived, as well as the platysma, which is one of the few remnants of the panniculus carnosus or skin musculature of the lower mammals. From the third branchiomere, the nerve of which is the ninth or glossopharyngeal, the stylo-pharyngeus and upper part of the pharyngeal constrictors are formed, while the fourth and fifth gill arches give rise to the muscles of the larynx and the lower part of the constrictors supplied by the vagus or tenth nerve. It is possible that parts of the sternomastoid and trapezius are also branchial in their origin, since they are supplied by the spinal accessory or eleventh nerve, but this is unsettled. The limb musculature is usually regarded as a sleeve-like outpushing of the external oblique stratum of the lateral ventral musculature of the trunk, and it is believed that parts of several myotomes are in this way pushed out in the growth of the limb bud. This process actually occurs in the lower vertebrates, and the nerve supplies provide strong presumptive evidence that this is the real phylogenetic history of the higher forms, though direct observation shows that the limb muscles of mammals are formed from the central mesoderm of the limb and at first are quite distinct from the myotomes of the trunk. A possible explanation of the difficulty is that this is another example of the slurring over of stages in phylogeny, but this is one of many obscure morphological points. The muscles of each limb are divided into a dorsal and ventral series, supplied by dorsal and ventral secondary divisions of the nerves in the limb plexuses, and these correspond to the original position of the limbs as they grow out from the embryo, so that in the upper extremity the back of the arm, forearm and dorsum of the hand are dorsal, while in the lower the dorsal surface is the front of the thigh and leg and the dorsum of the foot.

For further details *see* J. P. McMurrich, *Development of the Human Body* (London, 1923), and the writings of L. Bolk, *Morphol. Jahrb.* vols. xxi.–xxv.

COMPARATIVE ANATOMY

In the Acrania (*e.g., Amphioxus*) the simple arrangement of myotomes and myocommata seen in the early human embryo is permanent. The myotomes or muscle plates are < shaped, with their apices pointing toward the head end, each being supplied by its own spinal nerve. In the fishes this arrangement is largely

persistent, but each limb of the $<$ is bent on itself, so that the myotomes have now the shape of a ≶ the central angle of which corresponds to the lateral line of the fish. In the abdominal region, however, the myotomes fuse and rudiments of the recti and obliqui abdominis muscles of higher types are seen. In other regions too, such as the fins of fish and the tongue of the Cyclostomata (lamprey), specialized muscular bundles are separated off and are coincident with the acquirement of movements of these parts in different directions. In the amphibia the limb musculature becomes much more complex as the joints are formed, and many of the muscles can be homologized with those of mammals, though this is by no means always the case, while, in the abdominal region, a superficial delamination occurs, so that in many forms a *superficial* and *deep rectus abdominis* occurs as well as a *cutaneus abdominis* delaminated from the external oblique. It is probable that this delamination is the precursor of the panniculus carnosus or skin musculature of mammals. The branchial musculature also becomes much more complex, and the mylo-hyoid muscle, derived from the first branchial arch and lying beneath the floor of the mouth, is very noticeable and of great importance in breathing.

In the reptiles further differentiation of the muscles is seen, and with the acquirement of costal respiration the external and internal intercostals are formed by a delamination of the internal oblique stratum. In the dorsal region several of the longitudinal muscles which together make up the erector spinae are distinct, and a definite sphincter cloacae is formed round a cloacal aperture. In mammals certain muscles vary in their attachments or presence and absence in different orders, sub-orders and families, so that, were it not for the large amount of technical knowledge required in recognizing them, they might be useful from a classificatory point of view. There is, however, a greater gap between the musculature of man and that of the other Primates than there is between many different orders, and this is usually traceable either directly or indirectly to the assumption of the erect position.

The chief causes which produce changes of musculature are: (1) splitting, (2) fusion, (3) suppression either partial or complete, (4) shifting of origin, (5) shifting of insertion, (6) new formation, (7) transference of part of one muscle to another. In many of these cases the nerve supply gives an important clue to the change which has been effected. Splitting of a muscular mass is often the result of one part of a muscle being used separately, and a good example of this is the deep flexor mass of the forearm. In the lower mammals this mass rises from the flexor surface of the radius and ulna, and supplies tendons to the terminal phalanges of all five digits, but in man the thumb is used separately, and, in response to this, that part of the mass which goes to the thumb is completely split off into a separate muscle, the flexor longus pollicis. The process, however, is going farther, for we have acquired the habit of using our index finger alone for many purposes, and the index slip of the flexor profundus digitorum is in us almost as distinct a muscle as the flexor longus pollicis. Fusion may be either collateral or longitudinal. The former is seen in the case of the flexor carpi ulnaris. In many mammals (*e.g.*, the dog), there are two muscles inserted separately into the pisiform bone, one rising from the internal condyle of the humerus, the other from the olecranon process, but in many others (*e.g.*, man) the two muscles have fused. Longitudinal fusion is seen in the digastric, where the anterior belly is part of the first (mandibular) branchial arch and the posterior of the second or hyoid arch; in this case, as one would expect, the anterior belly is supplied by the fifth nerve and the posterior by the seventh. Partial suppression of a muscle is seen in the rhomboid sheet; in the lower mammals this rises from the head, neck and anterior (cephalic) thoracic spines, but in man the head and most of the neck part is completely suppressed. Complete suppression of a muscle is exemplified in the omo-trachelian, a muscle which runs from the cervical vertebrae to the acromian process and fixes the scapula for the strong action of the triceps in pronograde mammals; in man this strong action of the triceps is no longer needed for progression, and the fixing muscle has disappeared. Shifting of origin is seen in the short head of the biceps femoris. This in many lower mammals (*e.g.*, rabbit) is a muscle running from the tail to the lower leg; in many others (*e.g.*, monkeys and man) the origin has slipped down to the femur, and in the great anteater it is evident that the agitator caudae has been used as a *muscle slide,* because the short head of the biceps or tenuissimus has once been found rising from the surface of this muscle. Shifting of an insertion is not nearly as common as shifting of an origin; it is seen, however, in the peroneus tertius of man, in which part of the extensor longus digitorum has acquired a new attachment to the base of the fifth metatarsal bone. The new formation of a muscle is seen in the *stylo-hyoideus alter,* an occasional human muscle; in this the stylo-hyoid ligament has been converted into a muscle. The transference of part of one muscle to another is well shown by the human adductor magnus; here the fibres which pass from the tuber ischii to the condyle of the femur have a nerve supply from the great sciatic instead of the obturator, and in most lower mammals are a separate part of the hamstrings known as the *presemimembranosus.*

Anat. and Phys.* xxxii. 428; also accounts of the musculature of mammals, by Windle and Parsons, *Proc. Zool. Soc.* (1894, *seq.*); Humphry, *Observations in Myology* (1874). (F. G. P.)

MUSES, goddesses presiding over song and ultimately over the liberal arts generally (Μοῦσαι, originally *Μόντιαι, Μόνσαι "the mindful ones"). In Homer, they are represented as singing to the gods, to the accompaniment of Apollo, and as jealous of the attempt of Thamyris the Thracian bard to rival them (*Il.* i, 604; ii., 594 ff.), also as inspiring or instructing poets generally; sometimes a single Muse is invoked for that purpose (as *Od.*, i., 1), sometimes all (as *Il.*, ii., 484); but nothing is said of their number or names. In Hesiod there are nine Muses, daughters of Zeus and the Titaness Mnemosyne (Memory); their names are Clio, Euterpe, Thalia, Melpomene, Terpsichore, Erato, Polyhymnia, Urania, and Calliope. This is the canonical list; but there were many local variants; for example, it was said that originally but three Muses were worshipped on Helicon, and their names were *Melete, Mneme, Aoide* (Practice, Memory, Song). At Delphi also there were three, worshipped in connection with Apollo, who is often called *Musagetes,* or leader of the Muses; at Sicyon there were three, of whom one was called *Polumatheia* ("much learning"). We may, therefore, conclude that their names are much later than their cult. From the beginning they are associated with Thrace; Orpheus and Rhesus are sons of Muses, Thamyris is their unsuccessful rival, they are traditionally associated with Pieria, Leibethra, and Pimpleia, and the cult of their father Zeus is in very ancient times situated on Olympus. But quite early a cult almost more famous was established at Helicon in Boeotia. We may reasonably suppose that the worship of the Muses entered Greece with the Greeks and moved southward with them. As to their original functions, it has been suggested that they began as water-deities, a theory plausible enough in itself, since water is closely associated with inspiration, prophetic or poetical. But this does not account for the name [why should a deity of water be called "mindful"?] nor for the fact that in our earliest authorities the Muses are definitely goddesses of song, not water. They are, however, associated with holy streams or springs, Castalia, Hippocrene, and Aganippe.

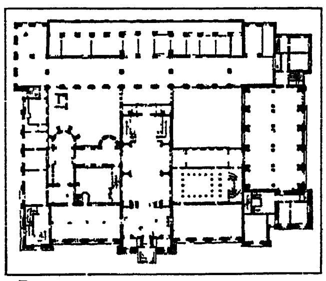
The assigning of different functions to individual Muses (*see* CALLIOPE) is late and erratic. The Romans often identified the Muses with the Camenae, who appear to have been deities of water; also perhaps connected with prophecy (*see* G. Wissowa, *Religion und Kultus,* 2nd ed., p. 219).

See Roscher's *Lexikon, s.v.*; L. R. Farnell, *Cults of the Greek States* (1896) v., p. 434 (references, p. 469).

MUSEUM ARCHITECTURE. Both art and scientific museums have the primary purpose of displaying collections of objects; consequently, certain features of architectural planning are common to both. Essentially, the plan of each must provide for the free and comfortable circulation of the public, an easy access to the various sections of the building and a coherent arrangement of rooms and galleries. An adequate lighting system

and an appropriate setting for the objects displayed must also be provided. It should be remembered that whereas in the plan of a museum of science the principal object is the logical sequence of exhibition groups, in a museum of art, the paintings and sculpture displayed require, in addition, a setting that will contribute to the awakening of a powerful and lasting impression in the spectator.

Art Museums.—The art museum is the modern development of the private art collections of older times. When, in due course, the State became the owner of such collections—by request, purchase or the fortunes of political upheavals—and when the democratic spirit of the 19th century impelled the owners of private collections to offer their treasures to public view, the original housing of these works of art was soon found to be inadequate, both for the increasing size of the collections and for their suitable display. The problem then confronting the architect was how to design buildings in which art collections could be enjoyed by the public, without making too great a demand on the exigencies of space. In many cases, existing buildings that no longer served their original purposes, were resorted to, the interiors being remodelled to meet the new requirements. Of this type are museums such as the Cluny, Carnavalet and Louvre in Paris, most of the Italian museums, the Belvedere in Vienna, and the museum of Nuremberg. Historical reconstitutions of interiors sometimes developed themselves, as though out of the abundance of arts and crafts materials such as were possessed by museums like the Cluny, in Paris, and the municipal museums in Florence, Venice, Belgium and Holland; sometimes they were designed intentionally, as in the museums of Munich, Darmstadt and Nuremberg; the Ryks museum, Amsterdam; Carnavalet, Paris; and the Markisches museum, Berlin. They were found not only to make a special appeal to the public, but also to add a new interest to the works exhibited.

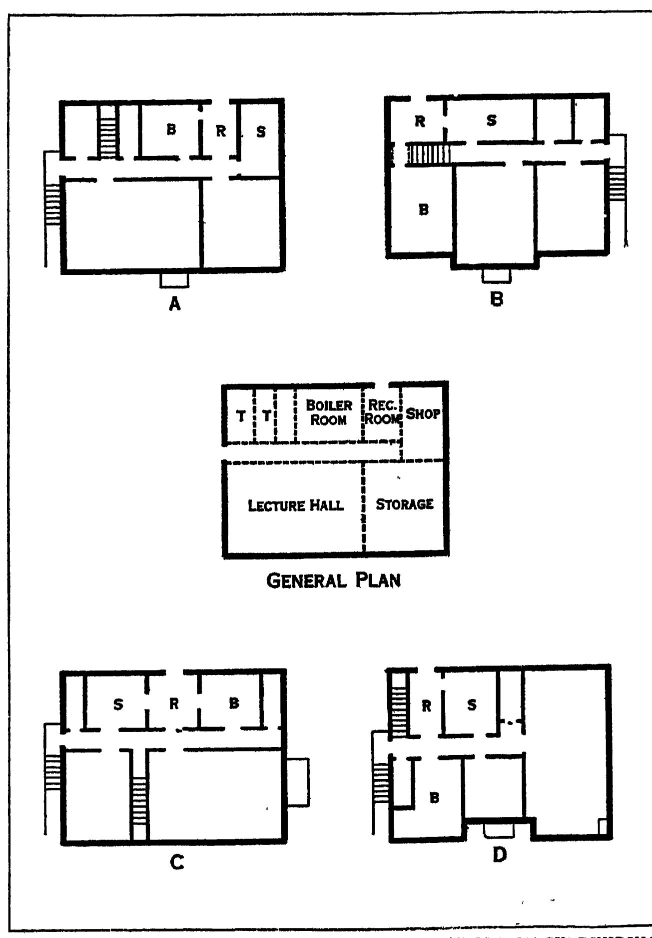


PLAN OF MUSEUM IN DARMSTADT

The museum of the 19th century was usually two storeys high, with services in the basement, and with an entrance hall leading to a monumental stairway. On the entrance floor were the collections of sculpture, though these were occasionally placed in a courtyard covered by a glass roof, and the collections of medals, furniture, pottery and textiles, all lighted by windows. The main floor was devoted to the picture galleries, uniformly lighted by skylights; the circulation flowed, usually, from room to room. The general architecture of the building was often in the Greek tradition, in homage to the century of Phidias. Representative museums of this type are: the old museum of Berlin, by Schenkel (1824), the Glyptothek at Munich, by Von Klenze (1830), the British museum, by Sir Charles Barry (1825–27), the National Gallery in London (1838), Dresden museum (1850), and the group of art and scientific museums at Vienna and Marseilles, France. This type is also the basis, in the United States, for such museums as the original unit of the Metropolitan Museum in New York, by Hunt, the Brooklyn Institute of Arts and Sciences, by McKim, Meade and White, the Museum of Toledo, and the Corcoran Art Gallery, Washington, D.C.

Recent Innovations.—One of the principal innovations of late years in museum planning is the provision of smaller rooms, suitable to the display of various works of art, classified according to the periods of their production. This feature is exemplified in the museums of Munich and Darmstadt (Alfred Messel, architect), and, in the United States, by the Detroit Institute of Arts (Paul Cret and Zantzinger, Borie and Medary, architects). In these museums, the formality of composition desirable for a public building is combined with some informality in the treatment of certain portions, thus allowing for the varied fenestrations belonging to the period rooms, and for picturesque courtyards for outdoor displays. Some recent museums provide also a covered courtyard, treated as an indoor garden, where visitors can find relaxation after their tour of the exhibition rooms, as in the Cleveland Museum of Art, the Detroit Institute of Arts, and the Freer Art Gallery, Washington, D.C., by Charles Platt. Other features which have developed in the best museum arrangements are: the displaying of selected exhibits in the main galleries and the relegation of exhibits of a merely historical or technical interest for students to special study-rooms; the equipment of services for storage; and the accommodations for educational work in lecture rooms, libraries, etc. These principles of museum planning are applicable to small town museums and private galleries, as well as to large State institutions. The various methods of lighting art galleries have excited wide controversy. Bad lighting may distort the room or make it necessary for the visitor, in order to avoid a glare, to remain at a fixed distance from a picture.

Scientific Museums.—Architecturally, the scientific museum makes much simpler demands than the art museum, the essentials of its plan being provisions for easy circulation, convenient and logical grouping of sections and good lighting. The problem of lighting is the most difficult to solve, owing to the prevalence of glass specimen cases, which, if the proper lighting is not effected, cause a glare that prevents a view of the contents. An interesting arrangement of zoological galleries has been made by Messel in the rear galleries of the Darmstadt museum. The National Museum (Hornblower and Marshall, architects) in Washington, D.C., also has a simple and effective plan; the entrance, in a rotunda, gives access to the three principal sections—biology, anthropology and geology—while minor galleries connect the branches of the "T." The Field Museum of Natural History, recently completed in Chicago (Graham, Anderson, Probst and White, architects, 1927), is one of the largest, occupying a rectangle of about 350 by 700 feet. Its floor space has been utilized intensively, and in it every effort is being made to present the specimens realistically by means of habitat groups whose settings and arrangements are not only accurate but works of art. In



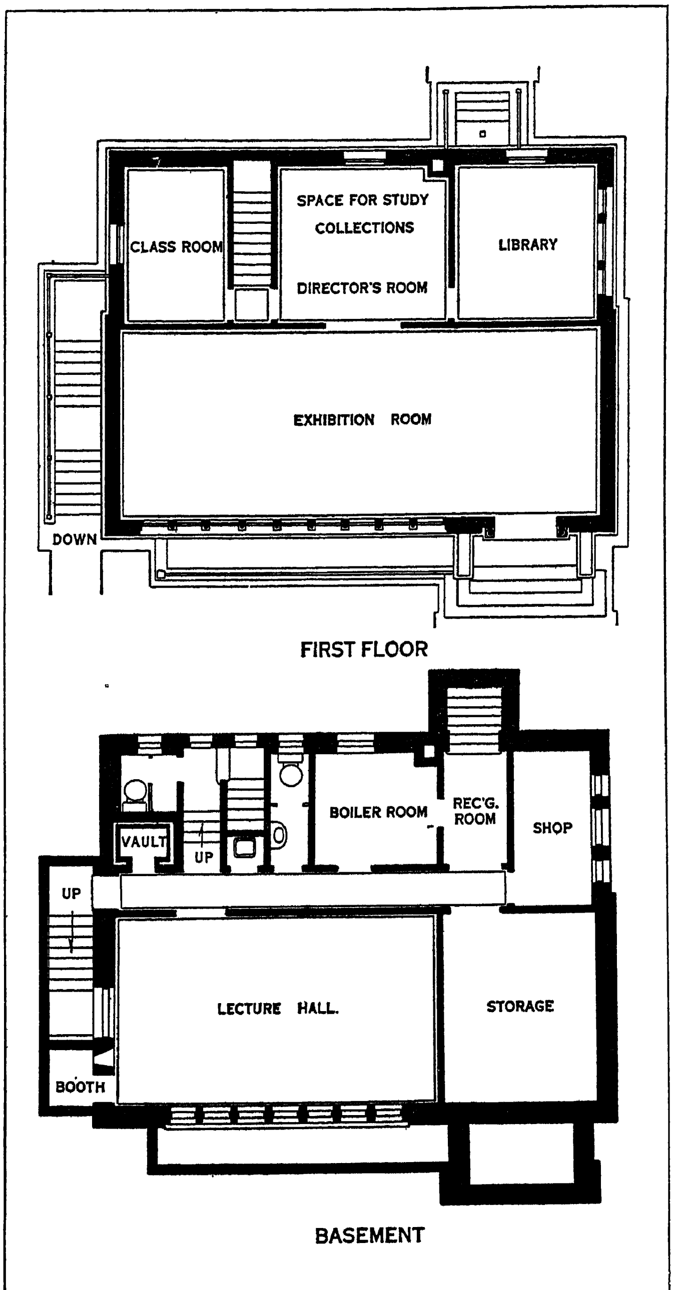
PLAN FOR SMALL MUSEUM SHOWING SEVERAL METHODS OF SUBDIVIDING THE GROUND OR BASEMENT FLOOR

Europe alone there are more than 2,000 scientific museums, few of which, however, rise to architectural distinction.

(P. P. Cr.)

MODERN MUSEUM PLANNING

Originally museums were thought of, planned, and built as storehouses for specimens, but with the recent, almost complete

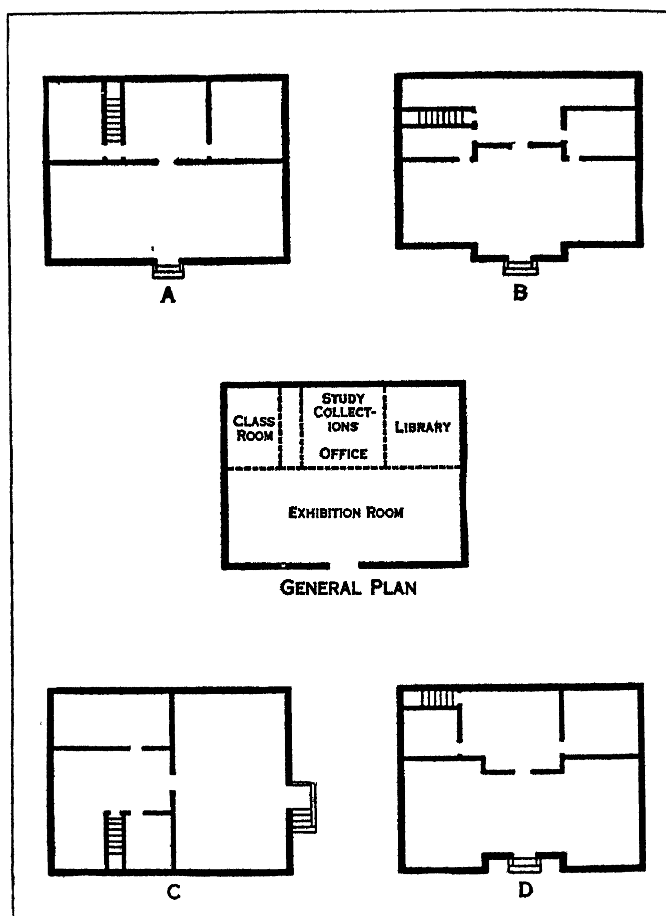


TOP, PLAN FOR FIRST FLOOR; BOTTOM, PLAN FOR BASEMENT

reversal of plan and scope, specimens now may even hold a relatively unimportant position as compared with other activities. Educational functions now tend to predominate and the curio type of collection is rapidly being replaced with material capable of instructing the museum visitor along sound cultural and practical lines. Carefully selected series of specimens illustrating the essential facts to be brought out have taken the place of closely packed rows of science museum material and of galleries of paintings hung row above row. The excess material, of little interest to the casual visitor, but often of value to the serious student, is segregated into well organized study or reserve collections, which may be examined on request.

The modern museum no longer restricts its activities to interesting the casual visitor who comes to its doors but organizes a constructive educational programme extending to the schools and many types of civic organizations. It supplies loan collections of specimens, sends out lecturers, furnishes motion pictures and other lecture material for outside use. It organizes and conducts excursions to nearby points where nature may be closely studied, and it even permits the public to engage in certain collecting and excavating projects. Within its own building it maintains an efficient guide service to its collections, appointing certain hours for children and young people. Its lecture halls and auditoriums furnish opportunities for talks illustrated by the surrounding museum material. Chamber music, organ recitals and theatrical productions have all been provided by museums. Organizations working along similar lines are encouraged to use museum facilities and many types of nature, art and hobby clubs, have been promoted by museums. The active modern museum presents to its public a constantly changing panorama of exhibits drawn from its own collections and from the many types of loan material which are circulated nationally.

New Needs Affect Design.—These changes in the basic theory of museum practice have been accompanied by altered conceptions of the architecture and arrangement of museums. Monumental architecture still has a strong appeal but there is increasing regard for improved internal arrangements. Most modern museums are built with a definite programme of expansion in view.

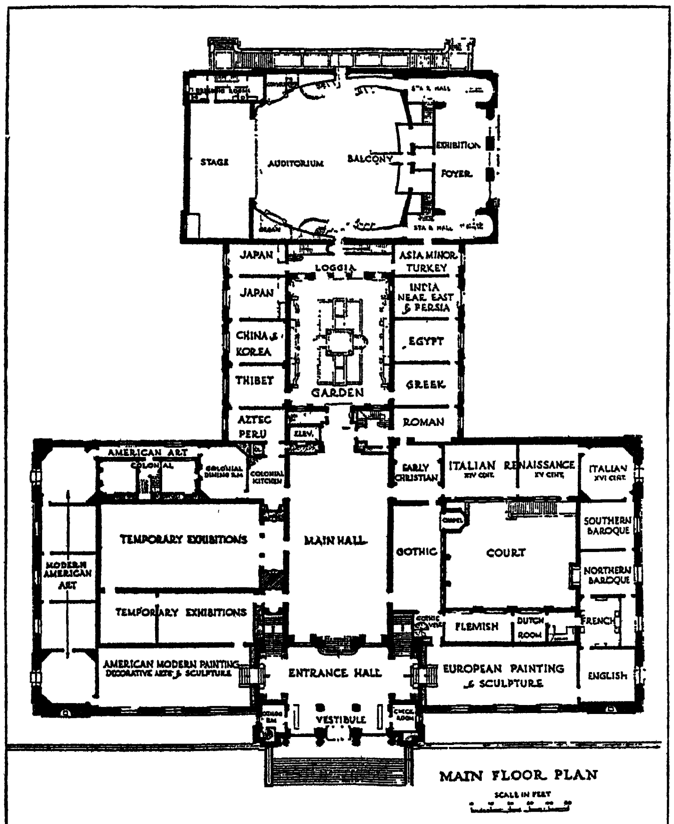


PLAN FOR SMALL MUSEUM SHOWING SEVERAL METHODS OF SUBDIVIDING THE MAIN FLOOR

Additions, as they become possible, are made with little disturbance of the original building. Wings or other prolongations provide additional exhibition space and make possible an increase in the number of activities. These principles may be applied as readily to the very small museum as to the institution starting with a substantial building fund In the case of a small museum a single façade may be completed, including the main entrance and making available one or two exhibition halls, moderate office space and service facilities. All furniture and cases are movable and partitions are of temporary nature wherever possible, so that adjust-

ments to changing conditions can be made easily.

Although excellent results are obtained with artificial lighting, museums are usually planned to utilize all daylight available. Careful experiments have shown that certain types of side and top lighting or combinations of the two meet practically every requirement. However, artificial lighting of the indirect variety makes it possible for a museum to be open in the evenings.



MAIN FLOOR PLAN OF DETROIT INSTITUTE OF THE FINE ARTS SHOWING THE WINDOW LIGHTING OF ROOMS AND THE GEOGRAPHIC AND CHRONOLOGICAL DISTRIBUTION OF EXHIBITS

Good planning of a museum, whether large or small, dictates a simple and readily understandable arrangement of exhibition halls, easily accessible from the main entrance and preferably laid out so that an orderly tour of the building or of individual sections is possible. Offices should be so placed that the public may reach them quickly and easily. Mechanical shops, usually occupying the ground floor or basement, are arranged with regard for the transferring of bulky objects from the shipping platform to any of the exhibition halls. Preparation departments should be near mechanical shops and accessible from the curatorial offices without traversing exhibition halls. Lecture halls and auditoriums should be provided with separate entrances from the street so that they may be used when other parts of the museum are closed.

In the case of a museum erected unit by unit the same general arrangements may be secured ultimately. The adding of a wing may extend the main exhibition floor and add one or more new galleries, the new basement space permitting expansion of store and mechanical space. An addition to the rear often contains an auditorium with small lecture halls or galleries below. Through this gradual expansion a museum may come to have a central courtyard which can be utilized in a variety of ways.

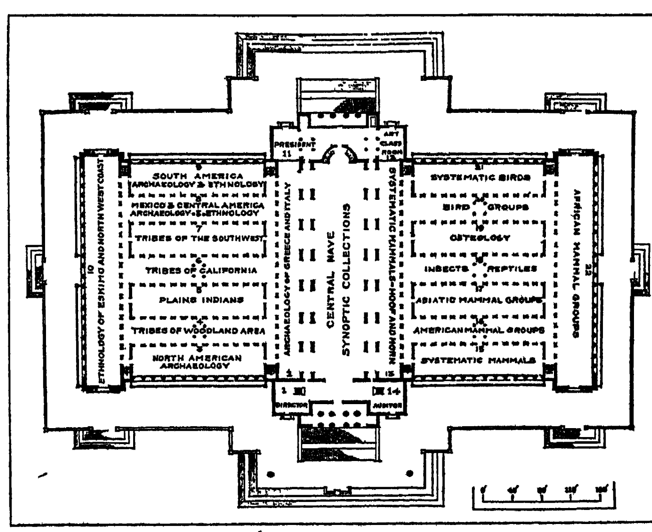
Except in the case of very small museums, most institutions are divided into departments, each of which is allotted certain exhibition space, curatorial offices, study rooms, work rooms, storage space and mechanical shops, when appropriate. A central library may be open to both visitors and the museum staff or a series of sectional libraries may place all publications on a single subject in close proximity to collections of the same nature.

Special activities of museums often include the printing of extensive series of publications, for which printing plants are installed. Photographic record work requires special equipment and many museums are prepared to sell at small cost a photograph of any object in their collections. Large museums find it economical to build their own exhibition cases and furniture and install woodworking shops for the purpose. Art museums have facilities for restoring paintings, casting and cleaning sculpture and renovating other objects. Science museums require taxidermists' shops and model making plants.

In addition to the well known museums of the world, such as the Louvre, Paris; the National Gallery, London; the British Museum, London; the Prado, Madrid; the Vatican Gallery, Rome; the Metropolitan Museum of Art, New York; the American Museum of Natural History, New York; the United States National Museum, Washington, D.C.; the Art Institute of Chicago; the Field Museum, Chicago; and the Museum of Fine Arts, Boston, there are many museums specializing in particular fields, and these often have buildings of special design.

Special Services.—School museums, of which there are several types, may require relatively little exhibition space but should have a large number of classrooms and laboratories, and a very complete library service. If the museum is engaged chiefly in supplying material for use in the schools its building may consist almost entirely of the workshops in which these collections are prepared and of facilities for handling and shipping. University museums usually have special facilities for class instruction in the museum and rearrange their exhibition cases as often as class requirements dictate.

Outdoor collections and outdoor museums are increasing in number and vary from the supplementary collection in a museum courtyard to the completely detached museum in the open air. Examples of the supplementary collections are the gardens of growing plants maintained by the Agricultural and Commercial Museum, Rio de Janeiro, Brazil, and the extensive garden of trees, plants and flowers which were utilized by the American Indians which has been planned by the Museum of the American Indian in New York. The outstanding example of this idea applied to the field of art is the Cloisters, of the Metropolitan Museum of Art, in New York, an extensive open air collection of sculpture and architectural details. The earliest open air museum is that



FIRST FLOOR PLAN OF THE FIELD MUSEUM, CHICAGO

known as Skansen, in Stockholm, Sweden, where, situated on a hillside overlooking the city, there is a group of peasant cottages, barns, sheds, windmills, belfries of churches and other pieces of native architecture. All are completely furnished and surrounded with appropriate things, such as carts and farm implements.

Certain large museums, such as the Toledo (Ohio) Museum of Art, have installed organs and give programmes of chamber music. The Art Institute of Chicago has a theatre of the drama. Astronomy has become susceptible of museum treatment through the recent invention, in Germany, of apparatus for projecting the

images of the stars and planets on the inner surface of a large dome. The interior of the dome, in which the audience is seated, resembles a large auditorium, the projection apparatus occupying a raised platform. The American Museum of Natural History, New York, is planning to erect such a planetarium as a part of its astronomical hall. Chicago is also to have a planetarium and several have already been put in operation in Germany and Russia.

Realistic Exhibits.—In addition to these special facilities of modern museums, which have a decided effect on the planning of buildings, the main exhibition halls of museums are also undergoing certain changes. Many art museums no longer arrange their objects by schools or countries but are constructing so-called period rooms. These interiors often consist of the original woodwork removed from celebrated buildings and re-erected in the museum. Such interiors act as a background for the arrangement of contemporary furniture, paintings and other objects. Excellent examples of this method are to be found in the Victoria and Albert Museum, London; the Municipal Museum, Amsterdam, Holland; the American wing of the Metropolitan Museum of Art; and the newly constructed Philadelphia Museum of Art.

Science museums are replacing exhaustive scientific series with habitat groups (*q.v.*), both in miniature and full scale. These show mammals, birds and fishes in their natural environment, and are often prepared on such a large scale as to fill whole exhibition halls. The industrial museums of Munich and Vienna have adopted the same principles in their field, erecting full scale models of mines and industrial plants and period rooms showing ancient shoemakers' shops, apothecaries' stores and similar industries. The arrangement of museum collections in this manner calls for either special planning or extensive alterations.

Extra-mural museum efforts have gone even further than the collecting and installing of museum material in more or less natural surroundings. There are now many instances of museums applying instructive labelling and supplemental exhibits to nature itself. An experiment of this type is the nature trail in the Palisades Interstate park, New York and New Jersey. A mile or more of path leading through the woods is lined with signs and labels directing attention to natural phenomena visible from the trail. Tracks of small animals, nests of birds, burrowings of insects, flowering plants and many similar things are marked for the benefit of the visitor in such a manner that specimens are utilized without removing them from their natural environment or resorting to such artificial expedients as stuffing and mounting. A modification of this idea, used in conjunction with small museums scattered through the park, is the placing of outdoor markers indicating important geological features.

As practically no two museums are alike either as to size or scope, the planning of each museum becomes a special problem solved best by a careful study of existing buildings and of the lessons learned by their use.

MUSEUMS AND ART GALLERIES. These two subjects are treated under the same heading because of their common aims and similar activities. (*See* also MUSEUMS OF SCIENCE.)

The public art gallery is a creation of the nineteenth century. Unconsciously, it is an assertion of the collecting instinct of the community; consciously, it has been designed to instruct the public, to educate artists, to encourage contemporary art by purchase, and to provide material for historical research.

ARRANGEMENT AND PLANNING

The method of housing and arranging picture collections has changed with changes in the purpose they are intended to serve. Broadly, until the last quarter of the nineteenth century, pictures were treated mainly as material for the decoration of walls; and the ideal picture gallery was regarded as a palatial building, containing a series of vast rooms on whose walls pictures were hung in tiers, according to size, shape and colour. This theory of arrangement was pushed to its extreme point, when in 1720–28 the Imperial collections were brought together in the Palace at Vienna, and the pictures were ruthlessly cut down, or added to, to fit the walls. Generally, however, its limitations were admitted by the provision of a series of cabinets for showing smaller pictures, though in each cabinet the pictures might be close packed in several rows. Another modification sometimes adopted (as in the Salon Carré of the Louvre, and the Tribuna of the Uffizi) was the hanging in one room, in comparative isolation, of a few selected pictures. In private galleries, the obvious drawback of such methods could to some extent be overcome by the use of ladders, or temporary removal of a picture from the wall; in public galleries such devices were impracticable. The first breach with established custom was largely due to the growing size of collections and took the form of establishing separate collections of modern pictures, and in most cases placing them in separate galleries. Thus came into existence the National Gallery of British Art (generally known as the Tate Gallery from its founder Sir Henry Tate) in London, the Luxembourg in Paris, the Gallery of Modern Art in Madrid, the Neue Pinacothek at Munich and the National Gallery at Berlin. As a rule, these modern galleries were intended for the work of native artists; but most of them now represent painters of all countries. For example, the Tate Gallery, which at one time contained only British work, now includes a large Modern Foreign section. Of specialization in other ways, examples are the National Portrait Galleries in London and in Edinburgh, containing portraits of men and women who figure in the history of the countries concerned. In some cases special galleries have been provided for sculpture; though more frequently this forms a section of a museum or art gallery and occasionally (as in the case of Renaissance Italian sculpture at the Kaiser Friedrich Museum) is exhibited with pictures of the same period and country. Specialization of galleries, however, did not in itself modify methods of arrangement. These have been altered partly by an increasing attention to the claims of students and of historical study; partly by growth of the feeling (largely due to influences from the Far East) that the individual picture was of greater importance than the decorative ensemble. As a result, the director of a modern gallery tries to satisfy four main requirements. (1) Decorative arrangement of the gallery, both on a large scale and in detail. (2) Grouping of pictures according to their country of origin, with subdivisions according to local schools, or according to artists; these groups and subdivisions being arranged within the gallery in chronological order. (3) Chronological arrangement of pictures within each group. (4) Such placing of each picture as will best facilitate its study and appreciation. These requirements are not always easily reconcilable. In particular, arrangement of a group of pictures to secure decorative balance of size and colour, may easily conflict with chronological order, or put a picture into a place where it cannot be well seen. On the other hand, systematic arrangement into schools and periods may prevent a decorative ensemble on a large scale; though often it favours decorative harmony in smaller groups and the appreciation of individual pictures, since works of the same school and period usually are similar in colour and tone, and even tend to conform to set sizes.

Decorative Arrangement and Classification.—Experiment as to the best method of compromise is still proceeding. As regards requirement (1), the general tendency is to abandon large-scale decorative effect, and aim at groups harmonious within themselves. This has in part been due to requirement (2), for which rooms of moderate size are best; since even when a gallery possesses large numbers of one school and period, subdivision on the basis of artists and the different manners of artists is always possible. The large and lofty rooms in which many of the older European collections are housed create difficulties, however; though attempts to overcome these have been made by the use of screens to divide up the rooms, usually at a complete sacrifice to a decorative ensemble. Another and more successful method

is to divide the walls into a series of bays by means of shallow buttresses, as in the new galleries at the Fitzwilliam Museum, Cambridge, thus providing a number of more or less self-contained units of space, while enabling the room itself to be large and imposing. This is a particularly useful device in small collections, where each school or artist is represented only by a few pictures, which do not call for a separate room. The third requirement of chronological arrangement within school or artist groups has rarely been attained, and has been almost invariably sacrificed to decorative arrangement of the pictures concerned, or to the interests of the individual picture. To secure the former, a method usually successful is to select a picture of suitable size or character as centre, and then to group symmetrically about it, by using pairs of pictures similar in size, tone and colour. Occasionally, two or more small pictures may be used to balance a larger one. For the study of individual pictures, hanging on one line level with the eye of the average spectator is generally recognised as most satisfactory. In large and lofty rooms, however, unless the pictures are large, this method leaves a large space of wall which overweights the pictures and spoils the decorative effect. In recently built galleries therefore the tendency has been to keep the rooms comparatively low. In existing high galleries, a useful device is to introduce a moulding along the upper part of the wall, above which the wall is of a lighter tone than that of the part against which the pictures hang; and so reduce the apparent height of the walls. Other important matters which affect both the individual picture and decorative ensemble are those of spacing, framing, background, and the use of accessory objects, such as sculpture and furniture. Too close hanging is admittedly inadvisable, though it may produce a pleasant pattern on the wall. The present tendency is to isolate and emphasize important pictures; sometimes by placing on an easel or screen, a method detrimental to the general appearance of a room, sometimes by careful placing and spacing, with perhaps the use of a special background. Single line hanging and adequate spacing, greatly increase the amount of wall space required, to an extent which in a large collection may often be prohibitive. The problem still waits satisfactory solution. On the Continent extensive loans for long periods (as at Berlin) the creation of subsidiary galleries (*e.g.*, Schleissheim, at Munich), and the use of storerooms, have considerably reduced the number of pictures on exhibition, though somewhat to the inconvenience of the student. The English National Gallery has created a Reference Section, in which the less important pictures are hung, open to the public on request. This method has been considerably explored and developed in the United States. The Boston Museum was a pioneer in placing exhibition and study galleries side by side, the latter being more tightly packed than the former, with the idea that for the specialist student amenities in display are less necessary than for the general public. The Fogg Museum has a similar system. This museum is arranged in the interests of a college community, the building is more than a museum; lectures, research, drawing, painting and all the functions of the Department of Fine Arts of Harvard university are carried on within it. To overcome the difficulty that the public and students are shy of asking admission to the study galleries, the new museum at Philadelphia has arranged the two groups on separate floors, both equally accessible to the public.

Wall Coverings.—Framing and wall covering are both matters into which individual taste enters too markedly to make generalization possible. Broadly, the modern tendency is to use frames either of the period in which the picture was painted, or reproductions of them: and to abandon rich, heavy backgrounds for lighter, neutral tints. The actual material employed varies with the wealth of the gallery concerned. Canvas painted a suitable colour is widely employed for convenience and cheapness, but is apt to have an unpleasant texture. In public galleries, tightly stretched backgrounds are usual, as opposed to the loosely hung material much favoured by private collectors, mainly for convenience in cleaning walls and in rearranging pictures. The use of appropriate accessories is another matter in which taste differs widely. Undoubtedly furniture, sculpture, etc., of appropriate character add greatly to the general decorative effect, and help to induce an atmosphere favourable to appreciation of the picture. On the other hand, many people find them distracting, and that the picture tends to become only one among several *objets d'art.*

Lighting.—Lighting is another problem which still awaits satisfactory solution. Top lighting is generally preferred, as it enables every wall to be utilized, and diminishes the risk of shadows being thrown on the pictures. In some modern galleries, however (*e.g.*, Detroit) and in the cabinets of older galleries, side lighting has been deliberately preferred, on the ground that certain pictures, such as those of the Dutch school, were painted to hang in places where side lighting was the rule. The top lighting of older galleries, conforming to the idea that a picture was primarily a means of decoration, was designed to illuminate the room as a whole, and is often so arranged that more light falls in the middle of the room than on the walls; with the inevitable result of reflections in the pictures, particularly distressing when these are glazed. Various devices, such as a velarium in the middle of the room, have been used to overcome this defect, but without conspicuous success except in countries such as Spain where the light is strong: since their main effect is to reduce the total amount of light in the room, and so to make it gloomy, while the amount falling on the walls still remains inadequate. In more modern galleries, a lantern roof, or a roof with solid centre and sloping glass sides, has met with some success. Excellent examples are the new galleries at the Fitzwilliam Museum, Cambridge, and at Cardiff. At the Tate Gallery, a gallery with one wall lit directly from above, the remainder of the room being in comparative darkness, has provided good visibility on that wall; but has been criticised as a waste of wall space, and as being gloomy. In some modern American galleries, an interesting and promising experiment is the use of a flat glass roof inside an ordinary glazed roof; the middle part of the inner roof being obscured by the use of a paint to a depth and area ascertained by experiment as satisfactory. (W. G. Co.)

BIBLIOGRAPHY.—Information as to the history, contents and buildings of particular galleries is generally given in the prefaces to their respective catalogues, both official and unofficial; but its extent varies considerably with the edition. Among the most useful editions are:—Amsterdam (1920), Antwerp (1920), Berlin (Kaiser Friedrich Museum), 2 vols. (1909), Brussels (1927), Budapest (1910), Dresden (1920), Florence (Uffizi) (1910), The Hague (1914), London (Wallace Collection) (1928), Madrid (Prado) (1922), ed. A. L. Mayer; Milan (Brera) (1908), ed. Ricci; Munich (Alte Pinacothek) (1925), New York (Metropolitan Museum) (1922), Paris (Luxembourg) (1913), ed. Benedite; Paris (Louvre) (N.D.), ed. Lafenestre and Richtenberger; Venice (Academia) (1924), Vienna (1925), ed. Glück.

The Making of the National Gallery, Sir Charles Holmes and C. H. Collins Baker; official history, *The Foundation of the National Gallery,* Burlington Magazine, April 1924, W. G. Constable. Information on the construction, organization and arrangement of art galleries, has appeared in the monthly bulletins of the American Museums, notably those of the Metropolitan Museum, Boston, Philadelphia and Detroit; also in *The Museums Journal* (Great Britain), *Proceedings of the American Association of Museums,* and *Museum Work* (Published by the American Association). Summaries of American experience, with suggestions, are: *Manual for Small Museums* (1927); Lawrence Vaile Coleman, and *The Museum* (1917), M. J. Talbot. Lighting methods (with diagrams and photographs) are treated in the *Journal of the R.I.B.A.*, 3rd Series, vols. xx., xxx., xxxii., J. Hurst Seager, *Country Life,* September 8 (1928), W. G. Constable.

HISTORY

The word "museum" is much older than the thing which it now denotes. Its meaning (Gr. μουσεῖον) is "a temple of the Muses." It could be applied metaphorically to any place where literature and the arts were cultivated, and its most famous use in antiquity was as the title of the Museum of Alexandria, founded and endowed by Alexander as a great library and home for scholars and for literary study. Its application to a collection of antiquities or natural history or science is necessarily quite modern, because the thing itself is modern. In antiquity and in the middle ages private individuals may occasionally have gathered together objects of art or of curiosity; but it was not a common custom, nor were museums recognized institutions until quite modern times. Their present status has been the work of the last two or three generations.

Origins.—The origin of museums, as we now know them, may be found in the Renaissance. The revival of interest in the classics led to an interest in the relics of classical antiquity which impelled individuals to collect them; while the growth of the spirit of curiosity, likewise the result of the Renaissance, led to the collection of objects connected with natural history or with science as then understood. In the collections made by princes, nobles, or humanists in the 16th and still more in the 17th century may be found, not merely the prototypes, but the actual beginnings, of some of the great museums of today. Thus the museum of Bologna may be traced back to the collections of the naturalist U. Aldrovandi (1527–1605); the armour, coins, and other antiquities collected by archduke Ferdinand II. at the end of the 16th century are at Vienna; the coins and natural history collections of Gaston, duke of Orleans (1608–60) are among the origins of the present national museums of these objects in Paris; N. Fabride Peiresc (1580–1637), to whom has been ascribed the foundation of the study of antiquity in France, collected plants and coins as well as books, and some of his medals passed to the Abbey of St. Geneviève; Thomas Howard, Earl of Arundel (1586–1646), collected not only the Arundel mss., now in the British Museum, but the Arundel Marbles, now at Oxford, and the Marlborough gems, now scattered among various collections; the collections of the two Tradescants (d. respectively 1638 and 1662), which constituted the first museum in England, and to which the name of museum seems first to have been applied, were acquired by Elias Ashmole in 1659 and are the basis of the Ashmolean Museum at Oxford. Later in the same century began the collections of Sir Hans Sloane (1660–1753) which, together with the mss. collected earlier by Sir Robert Cotton and later by the two Harleys, are the nucleus of the British Museum.

Very few, however, of the collections made in the 17th century have survived. They were the hobbies of individuals and were generally dispersed at their death. In the 18th century collecting became more methodical. Many of the princes of Germany and Italy formed collections of objects of art which became permanent ornaments of their courts. Young English nobles, making the grand tour, acquired objects of art and antiquity as well as pictures. The Ashmolean museum had become the property of the university in 1677; and in 1753 the bequest of Sir Hans Sloane's great collections to the nation led to the foundation of the British Museum. The great museums of Europe for the most part owe their origin to royal and princely collections, which in the course of political changes have become the property of the greater kingdoms or republics of today. To these must be added the museums belonging to municipalities, which are for the most part the outcome of the 19th century. These, as institutions, are deliberate growths, owing their origin to the spread of the desire for education; but in their contents they are often the victims of haphazard accumulations, being composed partly of local antiquities of all ages found in the neighbourhood, and partly (especially in England) of objects fortuitously collected by travellers and transferred to the local museum when they ceased to interest their owners. Natural history museums have frequently grown up in the same way; but the great national and university museums, together with some that have been formed by scientific societies, have been formed of set purpose and under scientific direction.

Development.—Within the last century progress has been systematized, and museums have acquired a recognized place in the national life.

GREAT BRITAIN

The first Museums Act was passed in England in 1845, and was followed by others; but the majority of the municipal museums owe their origin to the Act of 1891, now repealed and superseded by the Public Libraries Act of 1919. The recent (1928) report of Sir H. Miers to the Carnegie Trustees states that there were then 428 museums in England, 62 in Scotland, 26 in Wales, 8 in Northern Ireland, and 3 each in the Channel Islands and the Isle of Man,—a total of 530, great and small, including the national museums. In size and quality they vary very greatly, from large museums with collections of outstanding importance, such as Liverpool, Glasgow, Birmingham, Bristol, Manchester (where the museum is shared by the university and the city), Norwich, Hull, Exeter, Leicester and Sheffield, or smaller museums distinguished by special collections, such as York, Newcastle, Colchester (shared between a society and the Corporation), Taunton, Ipswich and Shrewsbury, or museums with a special purpose, such as the Horniman museum of ethnology in London or the Tolson museum of local history (natural and human) at Huddersfield, to small, neglected assemblages of fortuitous collections, badly housed, ill arranged and understaffed, which are too frequent throughout the country. An admirable survey of the whole field, with full statistics, is given in Sir H. Miers' report.

THE CONTINENT OF EUROPE

Every European country similarly possesses museums, national and municipal, which have for the most part had their origin in the collections of princes and nobles, supplemented in modern times by the deliberate educational policy of national or local governments.

In France the 12 national museums, including pre-eminently the Louvre, are governed by a Council of National Museums, under a director appointed by the President of the Republic on the recommendation of the Minister of Public Instruction. Museums under municipal or other local management are numerous.

In Italy no less than 71 museums and galleries are classed as national; to these must be added the great papal museums of the Vatican and Lateran and the municipal museums of Rome, Bologna, Ravenna, Siena, Palermo and elsewhere.

In Germany nearly all museums are the property of the several States, having grown up when they were separate kingdoms or principalities. The most important are the great group of museums of art, archaeology and ethnology at Berlin, Munich, Dresden and Nuremberg, with the Roman collections at Mainz and Trier, and museums of industrial art at Berlin and Hamburg. Of the many museums scattered over Europe, northern Africa, and southern Asia, most of them are of national interest only (*see* section IMPORTANT MUSEUMS AND ART GALLERIES).

THE UNITED STATES

In the U.S. the recent growth of museums has been amazing. They illustrate the modern development of museum theory. Instead of having developed fortuitously out of collections originally made to gratify the taste of a prince or the curiosity of a traveller, they have been for the most part deliberately created as part of the educational system of the country. Only a very few are national, namely the small group of museums at Washington administered by the Smithsonian Institution. A few are State museums, but not more than half a dozen of these are said to be well developed. There are some college and private museums, but the large majority, amounting to nearly 1,000 in all, is composed of municipal museums, supported partly by municipal funds but still more by private subscriptions and benefactions, the collection of which by organized propaganda forms an important part of the duties of the administration.

Money for buildings has been contributed with great liberality by private citizens, and since all are of quite recent date it is in America that museum planning and architecture can best be studied.

In respect of contents the American museums started at a disadvantage, for the field of free acquisition of Greek and Roman antiquities was closed before they came into existence. Nevertheless even in these provinces the museums of New York and Boston have succeeded in forming notable collections; while wherever there is an opening either for excavation or for purchase, American museums have been active and successful. The Metropolitan Museum has built up a magnificent Egyptian collection by many years of painstaking and scientific excavation. The American museum of Natural History has sent expeditions into many parts of the world, its most notable recent success having been won in Siberia. Boston and Philadelphia have had expeditions at work in Egypt, Palestine and Mesopotamia; in the

latter country the Philadelphia museum has shared with the British Museum the epoch-making discoveries at Ur. American antiquities are, of course, their natural province (*e.g.*, the Heye museum of the American Indian); but they have also taken advantage of the more recent opening up of the Far East to form the finest collections in existence of Chinese and Japanese art and archaeology. For fine buildings in which first-rate collections are shown with a due allowance of space, the traveller must visit the great cities of America rather than the crowded galleries of London, Paris and Rome.

Educational Value.—American museums, for the reasons given above, form the transition from the older to the more modern conceptions of a museum. A museum is not now regarded as a collection of curiosities, but as an engine of research and of popular education. Its duties are two-fold: to the student and to the general public.

The conception of the museum as the laboratory of the student followed next after the conception of it as a casual collection of objects of beauty or curiosity, and was the result of the spread of archaeological discovery and scientific research, exemplified by the excavations of Layard and Schliemann and the publication of Darwin's *Origin of Species* in the 19th century. The third conception of it, as an instrument for the education of the general public, is of still later growth. If a date is to be indicated, the Great Exhibition of 1851 (out of which grew, in England, the institutions now known as the Victoria and Albert Museum and the Science Museum) may be taken as marking its commencement; but its general recognition and acceptance belongs to the present generation, and perhaps is not fully realized yet. Sir H. Miers' report, already alluded to, shows how much remains to be done in order to qualify most of the local museums of Great Britain to take their place in the educational scheme; but the doctrine is now generally accepted, the press aids with ready publicity, and the public visit the museums in greater numbers and take a more intelligent interest in their contents.

Service to the Public.—The service of the museum to the general public is three-fold. First, it stimulates curiosity, the gratification of which increases knowledge. It makes a man more aware of the world in which he lives; of its extension in time and space, of the materials of which it is composed, of the trees and plants with which it is covered, of the animals that have inhabited it from the remotest ages until now, of the activities of man, of the history of his development, of his achievements in craftsmanship and art. It illustrates written history and enlarges a man's conception of the possibilities of his race; and so it plays its part in enlarging his mind, in multiplying his interests, and in making him a better citizen. Secondly, in some of its departments it ministers to the sense of beauty. It places before him the beautiful products of nature and of art. It shows him what man has been able to create out of clay or stone or metal or by the use of pigments, and so gives him the means of training his taste and developing a cultivated appreciation of the beautiful; a service which, in a world where so many live in the midst of man-created ugliness, is on no account to be minimised. And thirdly it provides a means of refreshing recreation and intellectual and aesthetic enjoyment.

This is the museum ideal: but to realize it conditions are needed which are not always, or indeed often, attainable. To attract and interest the public, not a mass of material is needed, as by the student, but a relatively small number of objects good of their kind, or intrinsically interesting, well displayed and clearly explained. The ideal museum would have one set of galleries for the general public, in which this method would be applied, and another set of rooms for the student, in which objects would be gathered in bulk, with all facilities for their examination. Unfortunately few museums, and none of the older ones, have been built on this principle. The original idea was to show everything; and now the galleries are overcrowded, and there is no adequate accommodation for study-series. The need, however, is now recognized, and there is no doubt that efforts will be made to supply it (*see* MUSEUM ARCHITECTURE).

The educational service of a museum is, or should be, not merely passive but active. It is not enough to build and stock a museum, and to leave the public to find out its value for themselves. That was the older policy, or lack of policy. A live museum now endeavours actively to attract the public and to interest it. The principal means are by labels, by guide-books, by photographs (including the popular picture postcards), by special exhibitions, by articles in the press, and by lectures in the galleries. Peripatetic lectures by educated guide-lecturers (as distinct from mercenary *ciceroni*) were, it is believed, first tried in the United States in 1907 and first systematized in London in 1911. They are now a recognized and popular feature in all the greater museums. Still more recently the use of museums as a regular part of the education of children has been developed, conspicuously so in America, where it has been found a great success.

Present Status.—The present position of museums may be briefly summarized as follows. Everywhere the national museums, the university museums, and a small number of municipal museums are thoroughly established as laboratories of research, with trained staffs and an equipment, more or less complete, of catalogues. Their value in this respect is unquestioned. They are mostly full to overflowing, yet must continue to add to their contents in order to keep abreast of the results of discoveries. Their main problem is the provision of storage and of accommodation for students. As instruments of general education and cultured recreation, their utility has recently been much more fully realized than before; but it cannot be doubted that further developments in this respect are possible and desirable. Public recognition of their value, as manifested in the press and in figures of attendances and sales of publications, is growing rapidly.

BIBLIOGRAPHY.—The only general history of museums is *Museums, their history and their use*, by David Murray (Glasgow, 1904), in three volumes, of which two are occupied by a bibliography, including catalogues and other works relating to particular museums and special collections. Much detailed information about the national museums, both in Great Britain and in other countries, is contained in the volume of evidence and appendices accompanying the Interim Report of the Royal Commission on National Museums and Galleries (1928); and Sir H. Miers' *Report on the Public Museums of the British Isles* (1928), prepared for the Carnegie Trustees, gives the fullest survey of the history and present condition of the municipal and other non-national museums, with a tabulated list of them. E. E. Lowe's *Report on American Museum Work*, for the same Trustees, gives a more summary statement of the position in America. The publications of the American Association of Museums, the *Museums Journal* of the Museums Association of Great Britain, and the *Museumskunde* of Berlin contain much information on both theory and practice. Among other books that may be mentioned are: Sir W. Flower, *Essays on Museums* (1898); M. T. Jackson, *The Museum* (1917); L. V. Coleman, *A Manual for Small Museums* (1927); C. R. Richards, *Industrial Art and the Museum* (1927). Information with regard to particular museums must be sought in their own catalogues and other publications. A series of separate histories of British and American Museums includes *The British Museum*, by H. C. Shelley (1911), *The Boston Museum of Fine Arts*, by J. de W. Addison (revised ed., 1924), the *Metropolitan Museum of New York* by D. L. Preyer (1909), and *The Art Treasures of Washington*, by H. W. Henderson (1912). An investigation into the principles and methods of exhibition in art museums is now being conducted by the Carnegie Corporation of New York. (F. G. K.)

IMPORTANT MUSEUMS AND ART GALLERIES

A short account of the collections, special exhibits and educational activities of the more important art museums of the world is given below.

GREAT BRITAIN

British Museum, The, London, Eng., has two main divisions—the Library and the Departments of Antiquities. The Library of Printed Books is probably the largest in the world: the Department of Manuscripts includes outstanding treasures such as the Codex Alexandrianus of the Greek Bible, the Lindisfarne Gospels of about A.D. 700, Queen Mary's Psalter of the 14th century, the great Cottonian, Harleian and Royal Collections of mss., the best collection of Greek papyrus from Egypt, and vast quantities of mediaeval and modern historical papers and literary autographs. The Print Room contains a large and well-balanced representation of drawings and every kind of print, with a growing Oriental col-

lection which includes the finest representation of Chinese painting in Europe. In the Departments of Antiquities Greek sculpture stands out conspicuous through the possession of the Elgin Marbles from the Parthenon at Athens, together with the Demeter of Cnidus, the Nereid Monument and the remains of the Mausoleum and the temples of Ephesus and Phigalia. The Egyptian collection is as fine as any outside Cairo, including notably the Rosetta Stone and large representative selections of sculpture, mummies, papyri and smaller objects. The Museum contains the recent revelations of Sumerian art of the fourth millenium B.C.

Victoria and Albert Museum, The, is located at South Kensington, London. Its primary object is to provide examples to illustrate the history of art, especially in relation to such manufactures and crafts as are associated with decoration and design. In 1852 the Museum of Ornamental Art was established at Marlborough House, and at that time the collection consisted of specimens, casts, etc., originally purchased for use in the School of Design, with objects acquired from the Great Exhibition of 1851.

The collections are classified by material and arranged in eight departments: (1) Architecture and Sculpture; (2) Ceramics; (3) Engraving, Illustration and Design; (4) Library and Book Production; (5) Metal Work; (6) Paintings; (7) Textiles; (8) Woodwork. The Department of Circulation consists of separate collections, not on exhibition, available for loan to other museums and schools of art. The museum's library contains about 150,000 volumes, dealing with fine and applied art, and a collection of about 250,000 photographs. (*See* LONDON.)

National Gallery, The, London, was founded in 1824, by the purchase of 38 pictures from the collection of J. J. Angerstein. The collection now contains about 1,750 works, exclusive of a considerable number at the National Gallery, Millbank (the Tate Gallery). The Gallery is unexcelled in the uniformly high quality of its pictures, and the number of masterpieces it possesses. Nowhere outside Italy is the Italian school so admirably represented, nor outside Holland, the Dutch school; while the collections of Flemish, Spanish, German and French work, though small, are very choice. The group of English paintings is without an equal. Among the most famous paintings in the gallery are those by Duccio, Masaccio, Piero della Francesca (here represented by an unrivalled group), Leonardo da Vinci ("Madonna of the Rocks"), Michelangelo (notably "The Entombment"), Raphael (including the famous "Ansidei Madonna"), Correggio, Mantegna, Giovanni Bellini, Titian, Tintoretto, Jan van Eyck ("John Arnolfini and His Wife"), Rubens, Rembrandt, De Hooch, Ruisdael, Velásquez, Holbein, Reynolds, Constable and Turner.

Wallace Collection, The, London, was brought together chiefly by the third and fourth Marquesses of Hertford and the natural son of the latter, Sir Richard Wallace. It was bequeathed to the British nation by his widow, who died in 1897. The family residence of the Hertfords and of Wallace, Hertford House in Manchester Square, was subsequently purchased by the Government and, after adaptation, opened to the public in June 1900. The collection is remarkable both for the high quality of its pieces and its variety. The series of revolutions and political upheavals in France (1789–1871) provided the fourth Marquess of Hertford and Sir Richard Wallace, both long residents in Paris, with unique opportunities for acquiring the chief treasures of the royal chateaux and the palaces of a ruined and disappearing nobility. French art of the 18th century is therefore the prevailing note of the collection. But the vigilance of their agents in England and elsewhere enabled them also to secure masterpieces of the first rank of the Italian, Spanish, Flemish, Dutch and English schools. What may be called the mediaeval section was added by Sir Richard Wallace, who bought *en bloc* two famous collections.

Walker Art Gallery, The, named after its donor, was a gift to the Corporation of Liverpool in 1887 by Sir Andrew Barclay Walker, Bart. The collection includes items of outstanding importance, such as: (1) The Roscoe Collection, which illustrates in outline European art from the 13th to the 16th century; (2) The Modern Collection, totalling over 2,000 works and representing the paintings of the Pre-Raphaelites, which include oils, chalk drawings, and water-colours; (3) sculpture; (4) the black and white section, including famous etchings. The only endowment possessed by the Gallery is a capital sum of £2,000 bequeathed by the 15th Earl of Derby, the income to be spent in the purchase of pictures "for the encouragement of rising artists."

Manchester Corporation Art Galleries. The City Art Gallery was originally designed by Sir Charles Barry for the Royal Manchester Institution, and was opened to the public in 1829. In 1882 the sum of £2,000 was set aside as an annual sum with which to purchase works of art. The bulk of the pictures in the collection belong to the English school and mainly cover the 19th century. In 1925 a collection of some 80 paintings, 400 water-colours and drawings, 300 woodcuts and 20 pieces of sculpture by modern artists was presented by Mr. Charles Rutherston of Bradford, who offered it on condition that it should be considered as a nucleus from which various works might be distributed on loan for short periods to the various art galleries and schools of art in Lancashire and Yorkshire. Numerous exhibitions are held in the gallery during the course of the year; lectures on various aspects of the fine and applied arts are given during the winter months; and some 500 elementary school children are brought to the Gallery every week and given instruction in the elementary principles of art. Besides, there are five branch galleries.

Bristol Museum and Art Gallery, The, was founded in 1820. The Art Gallery was presented by Sir William Henry Wills, Bart., in 1905, and has fine art collections of etchings, water-colours, oil paintings and ivories. Lectures and demonstrations are given by members of the staff in outlying parts of the city.

Dublin Museum, The, one of the most suitably housed and organized museums in Great Britain, is remarkable for its collection of Celtic antiquities. It has among its famous specimens of Irish art the shrine and bell of St. Patrick, the Tara brooch, the cross of Cong and the Ardagh chalice. The series of bronze and stone implements is famous.

Birmingham Museum and Art Gallery, The, with perhaps the finest provincial collection of industrial art, has made a reputation for special exhibitions of art.

National Museum of Wales, The, Cardiff, has an extensive department of art which occupies three galleries. The collection of sculpture, mostly by Welsh artists, is of particular interest. The ceramics collection represents the work of almost every Continental and British factory, including beautiful examples of extinct Welsh potteries.

Sir John Soane's Museum, London, in Lincoln's Inn Fields, was presented to the nation in 1835 by Sir John Soane. The collection includes Soane's own drawings, many of Hogarth's paintings, a splendid sarcophagus, sculptured in a single block of translucent Oriental alabaster from Alabastron, and many other valuable pieces. (X.)

THE CONTINENT OF EUROPE

France.—The *Louvre,* founded during the Revolutionary period, is not only noted as having the largest collection of art in the world, but is remarkable for the magnificence of its architecture. (*See* PARIS.) The *Cluny Museum* supplements the mediaeval collections of the Louvre with its select works of art, while the *Luxembourg Museum,* the *Municipal Museum,* the *Rodin Museum* and other smaller groups make Paris outstanding as an art centre. (*See* PARIS.)

Italy.—The *Museo Nazionale* at Naples contains the best arranged and best classified collection in the country. For historical importance its Roman art ranks with the collections of Rome and the Vatican. (*See* NAPLES.) Florence, known as the art capital of Italy, is the home of the famous *Uffizi Gallery,* founded by the Medici and known as one of the largest and choicest collections in the world. The collection is arranged chronologically by Schools, and shows the development of Italian painting from the 14th to the 16th century. The tapestries are also of historical importance. The *Pitti Palace,* the *Picture Gallery,* the *Academy of Fine Arts,* the *Archaeological Museum* and the *National Museum* in the Bargello are other large galleries. (*See* FLORENCE.) The museums of Rome are numerous, the Vatican alone containing at least six remarkable ones. The *Museo Nazionale* (by the

baths of Diocletian), the *Museo Capitolino* and the *Palazzo dei Conservatori* contain innumerable specimens of the finest classical art. (*See* also ROME.)

Germany and Austria.—The *Kaiser Friedrich Museum,* Berlin, has among its collections many antiquities of Babylon, Assyria, Syria and Phoenicia. (*See* BERLIN.) The *Old Museum,* housing only antique works of art, is especially interesting as an artistically unique building dating from 1828, while the *New Museum* contains a superb Egyptian collection, besides large groups of plaster casts, drawings and engravings. Schliemann's discoveries are housed in the *Ethnographic Museum.* The *National Galerie* is outstanding as a museum for paintings, dating from 1780 to the present time. Roman, French and German technical art can best be studied at the *Schloss Museum,* which has nearly 700 rooms. Under the empire it was furnished with quiet magnificence, being the royal palace. It contains the living and state rooms, formerly occupied by royalty, called the *King's Chambers,* the *Gobelin Gallery,* the Majolica Room, and immense collections of the various kinds of art, and well arranged. Dresden has many galleries of importance, as the *Johanneum,* the *Albertinum,* the *Zwinger* and the *Grüne Gewölbe.* (*See* DRESDEN.) The *Old Pinakothek* and the *National Museum* of Bavaria are at Munich (*q.v.*). Prague, Innsbruck and Budapest (*q.v.*) are respectively the homes of the National Museums of Bohemia, Tirol and Hungary. Besides the large natural history museum of Vienna, there is the *Imperial Art-History Museum* with collections of Greek, Roman and Egyptian antiquities, of coins and medals, industrial art, arms and armour, and many military trophies, relics and curiosities. (*See* VIENNA.)

Belgium and Holland.—The *Royal Museum of Fine Arts,* Brussels, has four divisions: (1) The *Musée d'Art Ancien* was established under the French régime, taking form in the eleventh year of the Republic when a group of paintings of the Old Masters was granted by the French administration. In 1841, after the development of the Gallery had been somewhat retarded under Dutch régime, it was purchased by the State. The Gallery is particularly rich in its collection of old paintings. Although the French note predominates, other schools are well represented: the Flemish school, with numerous paintings of Rubens, A. Van Dyck, Jordaens and the Antwerp masters; the Dutch school, with admirable works of Rembrandt, Von Goyen, Frans Hals, Jan Steen, etc.; and many paintings from various other foreign schools. (2) The *Musée d'Art Moderne,* which was founded during the Dutch régime, and which had a remarkable development, was reorganized after the World War with a view to making as excellent a collection of the Belgian school as possible. (3) The *Wiertz Museum* is entirely devoted to the works of painting and of sculpture of the Great Romantic painter, Antoine Wiertz (1806–65). (4) The *Gallery of Sculpture,* which was started in 1836 with the collection of sculpture from the studio of Mathieu Kessels, has considerable interest in the development of sculpture in Belgium, and some works of foreign schools add to the richness of the collection. The great central depository of Dutch art is in Amsterdam, where the *State Museum of the Netherlands,* generally known as the *Ryks Museum,* is located. (*See* AMSTERDAM.) Leyden university, The Hague and Rotterdam also have good collections.

Other Countries of Europe.—Spain has its *Museo del Prado* and the *Archaeological Museum,* of interest only in its collections of Moorish and Spanish art. (*See* MADRID.) The museums of the chief provinces are situated at Barcelona, Valencia, Granada and Seville. The *National Museum* of Portugal is at Lisbon (*q.v.*).

In Greece, the centre of all art and archaeology is Athens (*q.v.*), which has three museums, all devoted to Greek art: that of the *Acropolis,* that of the *Archaeological Society* (vases and terra cotta), and the *National Museum of Antiquities.*

In Switzerland, the *Swiss National Museum,* Zürich, is a model of arrangement and organization. Its collection of stained glass is of general importance, while the arrangement of rooms illustrating the historical progress of art is a special feature. Basle, Geneva, Lausanne and Bern have museums of great value to the Swiss people, keenly interested in art as they are.

Norway, Sweden and Denmark rank high as countries interested in their collections of art and archaeology, despite their reputed leaning toward museums of science and industry. Stockholm has three museums: the *Royal Palace,* with its unusual collection of costume and armour; the *Northern Museum,* which contains a considerable amount of modern and domestic art; the *National Museum of Sweden,* containing a general collection, well classified. The *National Museum of Denmark* at Copenhagen, however, must be classed with the few outstanding national museums of the world. The paintings form a complete record of the work of Danish artists from the end of the 18th century, and the engravings number more than 80,000. The *Thorwaldsen Museum,* named after perhaps the greatest of all northern sculptors, the *Museum of Industrial Art* and the *Danish Folk Museum* are also in Copenhagen. *Oslo* and *Bergen* contain many Norse antiquities.

In Russia, western art is found principally at Moscow and Leningrad. The *Hermitage Palace* in the latter city contains a selection of mediaeval objects of fabulous value, such as the ivories, the gold and silver objects illustrating the primitive arts and ornament of Scythia, Crimea and Caucasia. (*See* LENINGRAD; also MOSCOW.) Russian art predominates in other places, as in Kharkoff and Odessa (the university), Krasnoyarsk, with 12,000 specimens of Buriat art, etc., indicating interest in collecting even in the most remote parts of Siberia.

Various Other Countries.—There are several museums in India, the chief one being at Calcutta, devoted to Indian activities. Mention is only due the ones that are growing up under the direction of the Department of Archaeology, wisely established by Lord Curzon. The *Gizeh Museum of Egyptian Antiquities,* Cairo, is housed in a large building, well classified and liberally supported. Carthage and Tunis have small museums. The *Turkish Museum of Antiquities* at Constantinople has classical sculpture, but little else of significance. In the Orient about the only museums are found in Japan, a fuller description of which follows:

(F. L. D.)

JAPAN

Teishitsu Hakubutsu Kan (Imperial Household Museums) consists of the Tokyo Imperial Household Museum, the Nara Imperial Household Museum, and the Shōsō-in.

The Tokyo Imperial Household Museum, in Uyeno Park, Tokyo, dates from 1872. The main exhibition building, badly damaged by the earthquake in 1923, will be replaced by a new one. At the present time the Hyokeikan, which withstood the earthquake, is the only building now open to the public. The exhibition building contains two rooms for Oriental paintings, which are changed every month, a room for lacquer work, a room for Oriental wood, bamboo, metal, jade and ivory work, a room for the ceramic arts of Japan and China, two rooms for Japanese ancient sculptures, and three rooms devoted to historical and archaeological exhibits.

The Museum holds special exhibitions from time to time, and issues annual reports, reports of investigations, "Zuroku" (collotype reproduction of works of art with explanatory notes), "Gomotsu Jodai Senshokumon" (colour reproductions of 7th, 8th, and 9th century, dyed and textile fabrics in the Imperial Household Collection).

Nara Imperial Household Museum, in Nara Park, was completed in 1894. It contains the most representative collection of early Japanese sculpture, mainly in loan from different temples and shrines. It also contains archaeological and historical exhibits, as well as paintings.

The Shōsō-in (The Imperial Treasure House at Nara): the present wooden building dates from about 752, and contains treasures dedicated to the Great Buddha of Todaiji from the Imperial Household and kept under its supervision. To-day, as has been the practice for nearly 12 centuries, it is only in the presence of a special messenger from the Emperor that the doors are locked and sealed with a piece of paper bearing the Emperor's own signature, or the seals undone to open the doors. Of recent years it has been opened once a year, for about a fortnight, for airing, when accredited persons are allowed to see the treasures in the building. The most important treasures therein preserved are those which once belonged to the Emperor Shōmu, upon whose

death, in 756, his devout consort, the Dowager Empress Kōmyo, collected the things left by the Emperor and dedicated them to the Great Buddha, whose gigantic image the Emperor had caused to be created four years previously. The "Memorandum of Things Dedicated" by the Empress Kōmyo, dated June 21, 756, which marks the inception of the present Shōsō-in collection, is still preserved.

The Kyoto Museum: built in 1895 as one of the Imperial Household Museums, it remained as such for about thirty years, when it was given to the City of Kyoto. While it contains a good section of sculpture, it specializes more or less in paintings, mostly borrowed from different temples and shrines, and those exhibited are changed from time to time. (J. Har.)

THE UNITED STATES

Metropolitan Museum of Art, The, of New York City, was incorporated on April 13, 1870, "for the purpose of establishing and maintaining . . . a Museum and library of art, of encouraging and developing the study of the fine arts, and the application of arts to manufacture and practical life, of advancing the general knowledge of kindred subjects, and, to that end, of furnishing popular instruction." Its collections include Egyptian and classical antiquities, painting, sculpture and architecture, the decorative arts (furniture, metal-work, ceramics, glass, textiles, costumes, etc.), musical instruments, and arms and armour. Among the valuable gifts are the Altman collection and the Pierpont Morgan collection of European decorative arts, chronologically arranged from the Merovingian period to the 19th century. The latter collection occupies an entire wing, and another wing, the gift of Mr. and Mrs. Robert W. de Forest, is devoted to early American art. The Museum is owned and administered by a board of 21 elective trustees, and 4 ex-officio, representing the City of New York and the National Academy of Design. Its building, containing exhibition floor space of over 280,000 sq.ft., was erected by and leased from the City of New York. The yearly cost of administration is met by interest on endowment funds, an appropriation from the city for upkeep and salaries, membership dues, sale of publications and fees for admission, instruction, lecture courses, etc. The membership of the museum in 1928 was about 14,000.

Museum of Fine Arts, The, Boston, Mass., was incorporated on February 4, 1870, for the purpose of collecting and exhibiting works of art and of affording instruction in the fine arts. It was created by a group of private citizens and has always been supported by private gifts, bequests and annual subscriptions, without aid from the city or the State. In this respect it occupies a unique position among the greater museums of the world. It is administered by a board of trustees including representatives from Harvard university, the Boston Athenaeum, the Massachusetts Institute of Technology, the city, and the State. The museum maintains permanent free public exhibitions of original works of the art of Egypt, Greece, Rome, the Orient, modern Europe and America, supplemented to a limited extent by reproductions. Its outstanding collections are those of Chinese and Japanese, East Indian, Egyptian and Classical art; its print collection ranks first in America.

For *Art Institute of Chicago, The, see* vol. XI.

Brooklyn Museum, The, see Brooklyn Institute of Arts and Sciences.

Peabody Museum of American Archaeology and Ethnology, a museum founded by George Peabody at Harvard university in 1866, was the first anthropological museum in the United States. Its building, begun in 1877, enlarged in 1889 and again greatly enlarged in 1914, forms part of the university museum. Originally founded to comprise collections relating only to the past and present aboriginal peoples of the New World, its scope has been gradually widened, until it now includes archaeological and ethnological collections from all over the world. Aided by generous gifts of funds, it has since 1891 specialized in the archaeological exploration of the Mayan region of Central America, although in addition numerous investigations in various parts of the United States have been carried on, and expeditions to South America, Asia and Africa have also been sent out. The museum library contains complete sets of practically all anthropological and archaeological journals, and comprised in 1928 a total of about 20,000 volumes.

Fogg Museum of Art, The, Harvard University, Cambridge, Mass., was founded by Mrs. Elizabeth Fogg, and bequeathed to the university. The original building was completed in 1895 and used until 1927, when a new and adequate structure, planned by museum specialists working in collaboration with the architects, was dedicated and opened to the university and the public. The museum is a laboratory for the Fine Arts Department of the College, the collections being brought together with the idea of illustrating with original material the work carried on in the courses of study. Among the outstanding collections are those of prints, old masters' drawings and early Italian pictures.

National Gallery of Art, The, Washington, D.C., organized in 1920, as a department of the Smithsonian Institution, comprises two grand divisions: the National Gallery proper, and the Freer Gallery. The former occupies available space in the Smithsonian Institution building and in the old and new museums; the latter occupies exclusively a separate building, and is described below.

Freer Gallery of Art, The, Washington, D.C., is devoted primarily to the study and acquisition of the fine arts of Asia, and, secondarily, to the display and preservation of a group of works by American artists. These collections were brought together by Charles Lang Freer, of Detroit, and, together with the building and a fund for their development, were given by him to the nation, under the trusteeship of the Smithsonian Institution. Most important is a section devoted to the work of Whistler, including oil paintings, water colours, pastels, etchings, lithographs, engravings and drawings. Many American painters are represented. Eastern potteries, sculpture, bronzes, jades, etc., are present, some as early as the Chou Dynasty. The Persian, Mohammedan, Egyptian and Byzantine art collections are outstanding. The Freer Gallery was designed by Charles A. Platt.

Cincinnati Museum Association, Cincinnati, Ohio, is divided into two departments: the Museum proper and the Art Academy, or school. The collections embrace: the graphic arts—painting, drawing, etching, etc., the most notable being the collection of contemporary American paintings; sculpture—casts of Egyptian, Assyrian, Greek, Roman, Gothic, Renaissance and Modern works; metal work—originals and reproductions of silversmiths' and goldsmiths' works; arms and armour; textiles—including an important series of Indian shawls and a large collection of American lace. Besides the interesting groups of ceramics, costumes and musical instruments from all countries, there are over 30,000 specimens of American archaeology and ethnology.

Cleveland Museum of Art, The, Cleveland, Ohio, opened in 1916, is one of the outstanding museums of the United States. Its permanent collections include the Egyptian, classical, mediaeval and modern Western arts, with a notable single group of the decorative arts. The educational work covers a broad field and is an important factor in its success: courses of lectures, children's entertainments, clubs and conventions, exhibits, classes for art students, etc. A publicity department maintains contact between the museum and the local press by furnishing information, news items, photographs and copy.

Pennsylvania Museum, The, Philadelphia, Pa., covers the general field of European, American and Oriental art, chiefly in the periods since the beginning of the Christian era. Special emphasis is laid on the decorative arts, such as woodwork, furniture, textiles and metal work, and particularly important are the collections of ceramics and silver. The School of Industrial Art is a part of the organization, and with special exhibitions and competent instruction in the fine arts, the educational programme fills an important place. The museum is maintained by the city, supplemented by a membership of over 3,000 with annual dues.

Philadelphia Museum of Art, The, with the finest building of the Greek spirit in the modern world, is outstanding in its number of private collections and its importance as an educational institution.

Carnegie Institute, Pittsburgh, Pa., founded 1896, embraces the following departments: library, fine arts, museum, music, library

school, technology. The collections and activities of the museum cover both the natural sciences and the applied arts. Of particular importance is the collection of coins and medals and the various pieces of art work in metals. Considerable interest is manifested in contemporary American paintings, and the International Exhibition of paintings is held here annually. Other special exhibitions are presented throughout the year, and a large educational programme, including children's drawing classes and entertainments and a series of art lectures for adults, is maintained.

Detroit Institute of Arts, The, Detroit, Mich., incorporated in 1885 and reinstalled in an elaborate and modern building in 1927, includes a large collection of art works and a wide scope of educational activities. The museum has an interesting arrangement of the collections on one main floor in a series of period rooms, together with a pleasing semblance of their original setting. This floor is divided into three main sections: European, American and Asiatic. The Institute has provided educational facilities for students of the fine arts, such as study rooms, a lecture hall and a large auditorium equipped with a fine stage and a pipe organ.

Baltimore Museum of Art, The, which was founded in 1923 (Baltimore, Md.) moved into a new and up-to-date building in 1929. The collections are largely loan exhibitions, including paintings and sculpture by both American and foreign artists. Among the permanent treasures is an interesting group of East Indian metal and Cypriote antiquities. The educational work includes lectures, gallery tours for children, and the distribution of art collections and lantern slides among the schools.

City Art Museum of St. Louis, The, founded in 1879 as the St. Louis Museum of Fine Arts and reorganized in 1908, has an interesting group of collections, small but of unusual beauty. American paintings have received special attention, and an exhibition of invited paintings by American artists is assembled annually, selected largely from important exhibitions held at Chicago, Washington, Philadelphia, New York and Pittsburgh. These, with splendid examples of American sculpture, constitute one of the most representative collections of modern American art.

Denver Art Museum, The, Denver, Colo., is specializing in two regional art collections—the American Indian and the Spanish-American art. The Museum is especially interested in fostering the spirit of creative art and encouraging worthy students of art.

Fine Arts Society of San Diego, The, San Diego, Calif., established in 1926, is significant in its unique collection of old and modern Spanish art, as well as contemporary American art, which is almost exclusively in the field of paintings. It has a membership of more than 1,000.

Museum of the American Indian, The, Heye Foundation, New York City, was opened in 1922. It has over 2,000,000 exhibits and can display only about one-quarter of these at one time on the three floors that are devoted to exhibition rooms. The sole aim of the Museum is to gather and preserve for students everything useful in illustrating and elucidating the anthropology of the aborigines of the Western hemisphere. The field work, the publications and the monographs are notable.

Hispanic Society of America, The, was founded in 1904 in New York City. Its library and museum were designed to be a link between the English, Spanish and Portuguese speaking peoples—their languages, literature, art and history. A collection of paintings, manuscripts, maps and coins, and a library of 100,000 books form the most notable Hispanic collection in America. The society has held several outstanding exhibitions, among them the works of Sorolla, Zuloaga, Cervantes and Lope de Vega, as well as of collections of sculpture, photographs, prints, etc., and has issued more than 180 publications in Spanish history, literature and art.

Milwaukee Art Institute, The, Milwaukee, Wis., organized in 1910, is noted for its public activities as a civic centre—its great number of temporary exhibitions, gallery tours for children, entertainments for outside organizations, and free lectures.

Corcoran Gallery of Art, The, Washington, D.C., was founded in 1869. Special attention has of late been given to the acquisition of works by the American painters and sculptors, with a view to making the collection as representative as possible. A free art school is conducted in connection with the gallery.

Toledo Museum of Art, The, Toledo, Ohio, incorporated in 1901, has among its many collections perhaps the finest display of ancient glass in the world. The group of early printed books and manuscripts is also a remarkable one in that it shows the entire evolution of the art of writing and printing. The Museum has a vast educational programme: Sunday concerts, evening lectures, art lectures for children, etc. (F. L. D.)

MUSEUMS OF SCIENCE. The term "museum" originally meant the "Temple of the Muses," but now the conception is entirely altered. In the ancient world there were collections of paintings and statuary in the temples and palaces of Greece and Rome. Alexander the Great gave large sums of money to his illustrious teacher Aristotle and also sent him Natural History collections from the lands he conquered.

The "museum" at Alexandria was composed of a series of associated colleges which dealt with the muses and the arts. When this museum was burnt down the term fell into disuse, and there is nowhere in the world an institute corresponding to it. Not until the 15th century when there was a revival of interest in classical antiquities was any attempt made to "collect," but about this time one of the hobbies of the wealthy was to assemble together collections of statuary, inscriptions, gems, coins, medals, manuscripts and other relics of the past. This was followed by others who took up the task of collecting plants, minerals and curious animals, and among the more famous early collectors of objects of natural history may be mentioned Georg Agricola (1490–1555) who has been styled the "father of mineralogy." By his labours the elector Augustus of Saxony was induced to establish the *Kunst und Naturalien Kammer,* which has since expanded into the various museums at Dresden. One of his contemporaries was Conrad Gesner of Zürich (1516–1565), "the German Pliny," whose writings are still resorted to by the curious. Others whose names are familiar were Pierre Bélon (1517–1564), professor at the Collège de France; Andrea Cesalpini (1519–1603), whose herbarium is still preserved at Florence; Ulissi Aldrovandi (1522–1605), remnants of whose collections still exist at Bologna; Ole Worm (1588–1654), a Danish physician, after whom the so-called "Wormian bones" of the skull are named, and who was one of the first to cultivate what is now known as the science of prehistoric archaeology. The first person to elaborate and present to modern minds the thought of an institution which should assemble within its walls the things which men wish to see and study was Bacon, who in his *New Atlantis* (1627) broadly sketched the outline of a great national museum of science and art.

THE BRITISH EMPIRE

The oldest science museum in Great Britain is the Ashmolean museum which was built in 1679 by the University of Oxford to house the collection of natural history objects and some few archaeological rarities that had been publicly exhibited by the Tradescants in London, and had been made over by deed of gift by the younger Tradescant to his friend Elias Ashmole in 1662. Under the brothers Duncan, in the first half of the 19th century the museum enjoyed a wide reputation as a natural history museum of importance, and it preserved this character until 1860 when the zoological and botanical collections were moved to the New University museum.

In 1925 the old gallery was reopened as a museum for illustrating the history of science, and more especially of science in Oxford, by contemporary scientific instruments. A superb collection of ancient mathematical instruments, astrolabes, sundials and other apparatus was given to the university by Dr. Lewis Evans.

The most famous of English collectors in his time was Sir Hans Sloane (1669–1753), whose vast collections, including those of Pitiver, Courten, Merret, Plukenet and Buddle, were by his will bequeathed to the British nation on condition that parliament paid his heirs the sum of £20,000. The bequest was accepted and with the library of George II., which was also bequeathed to the nation, was the foundation of the British Museum in Bloomsbury, London. It was opened in 1750.

London.—The greatest museum in London is the British Museum, while the Natural History Department at South Ken-

sington with its wealth of types is the most important collection of its kind in the world. The museum of Practical Geology, Jermyn Street, contains an extensive collection and a very complete series of specimens illustrative of the petrography and palaeontology of the British Islands. The most recent museum in London is the Science Museum. In 1856 the collections illustrating science and art which had been brought together at Marlborough House was transferred to the South Kensington Museum which was opened by Queen Victoria in 1857. In 1896 the art collection was transferred to what is known as the Victoria and Albert museum, opened by Edward VII. in 1909; from this date the science collection was styled the Science museum. The main objects of this museum are (1) that so far as possible by means of exhibiting scientific instruments, apparatus, machines and other objects, the collections in the Science museum should afford illustrations and exposition of the various branches of science within this field and by their application in the arts and industries; (2) that the museum should also be a home for the preservation of appliances which hold an honoured place in the progress of science or in the history of invention.

At Kew Gardens there is a wonderful herbarium and general botanical collections very rich in types. The Hunterian museum of the Royal College of Surgeons devotes itself almost entirely to anatomy, both human and comparative and also to pathology. The Horniman museum, Forest Hill, S.E. owes its origin to collections of a miscellaneous character brought together by John E. Horniman. In 1901 he presented to the London County Council, for the use of the people of London, the existing building and the whole of his collections. Since the museum came under the control of the London County Council its character has been transformed, both by the more precise definition of its scope and intention, and by the expansion and re-arrangement of the collections along predetermined lines. It now deals with only two subjects, zoology and anthropology (including archaeology and ethnology). In general, its object may be said to be the illustration of the working of the evolutionary principle in relation to animals and man, and to human artefacts.

Liverpool.—The Liverpool museums are the largest of the provincial museums and owe their origin to two generous benefactors, (1) Lord Derby who presented his natural history collections, and (2) Joseph Mayer who presented his collections of antiques to the corporation. There are six separate departments, viz.:—botany, geology, invertebrate zoology, vertebrate zoology, archaeology and ethnology, while one section contains a large collection of ship models and pictures illustrative of the history of shipping. There is also a large collection of ceramics. The Egyptological collection is very extensive. There is also an aquarium. The zoological collections are extremely important more especially in ornithology which is very rich in types. One section is devoted to "old Liverpool."

Manchester.—The Manchester museum fulfills a dual purpose; it is a municipal museum and also a university museum. Instruction in science is given in the museum to 100 classes of elementary school children every week.

Bristol.—Bristol museum is now very important and contains departments of geology, zoology, botany and archaeology. A section is devoted to Bristol antiquities.

Hull.—Hull is a city of museums; there are the Natural History museum, Wilberforce house, the museum of fisheries and shipping, the Mortimer collection of prehistoric antiquities, the museum of commerce and transport, and the Folk Lore museum in the Tithebarn, Easington.

Two large private museums are worthy of note, the zoological museum, Tring, belonging to Lord Rothschild which deals exclusively with ornithology and entomology, and the Pitt Rivers museum at Farnham, Dorset, which is designed to illustrate the evolution of culture.

Scotland.—The Royal Scottish museum, Edinburgh, dates from 1854 and contains very valuable collections in the following departments, art and ethnography, natural history, technology and geology. The National Museum of Antiquities of Scotland in Edinburgh is the outcome of a donation of a collection of antiquities, coins and manuscripts by the Society of Antiquaries of Scotland in 1851. In the Kelvin Grove art gallery and museum in Glasgow there are extensive collections, the natural history and the shipping being the most important. The museums of the University of Glasgow are also noteworthy, the recently opened Zoological museum being remarkably fine.

Wales.—The National Museum of Wales in Cardiff which was granted its Royal Charter in 1907 and opened by George V. in 1927 is a most remarkable institution. Its purpose is "to teach the world about Wales, and the Welsh people about their own fatherland." This purpose it fulfills by collecting and preserving all kinds of material bearing on the geology, botany, zoology and archaeology of Wales.

Ireland.—The Science museum at Dublin, and the museum at Belfast both contain science collections of importance.

In the British Isles there are about 462 museums; these may be divided into five main groups, (1) those devoted entirely to natural history (22); (2) historical collections including War Memorial houses (30), Roman or Pre-Roman collections (15), Naval and Military museums (10), and period museums (16), total 71; (3) special teaching and research museums (60), and (4) museums of industrial character (16). The remainder to the number of about 300 are museums of general character and the exhibits usually comprise at least something of archaeology, local antiquities, natural history and miscellaneous ethnographical objects, and sometimes war relics.

India.—In Calcutta there are, (1) The Indian museum, which is especially rich in the marine fauna of the Indian Ocean and contains the finest collection of vertebrate fossils from the Siwalik Hills, (2) The Geological museum of the Government Survey of India, and (3) The herbarium of the Royal Botanical gardens. In Bombay there are (1) The Victoria and Albert museum and (2) The museum of the Bombay Natural History Society which is mainly Zoological and contains the finest collection of horned heads in India. The Government museum in Madras is also worthy of note.

Australia.—The Queensland museum, Brisbane, contains large ethnological collections from Papua of outstanding importance and an aboriginal court of great interest. The fauna of Queensland is also well represented. The Geological Survey museum, also at Brisbane, contains extensive geological collections mainly from Queensland. The South Australian museum at Adelaide is devoted specially to collections illustrating the ethnology and natural history of Australia. At Melbourne there are two very important museums, (1) The National Museum of Victoria which contains large collections illustrating the zoology, palaeontology and ethnology of Australia, and (2) the national herbarium of Victoria. The Macleay museum of the university, Sydney, contains a number of special collections, the most noteworthy being the Macleay entomological collection; the Jensen alkaline rock collection; the collection of Antarctic rocks from Shackleton's first expedition, and the Australian palaeontological collection. The Technological museum contains minerals from all sources, *e.g.*, European building and ornamental stones, systematic collections of rocks, timbers and commercial plants from all parts of the world. Australia is represented by industrial minerals and the systematic collection of Australian rocks, building and ornamental stones, also a collection of Australian insect pests Sections include shipping and aeroplane models.

New Zealand.—The Canterbury museum, Christchurch, is specially rich in local collections devoted to the fauna, flora and geology of New Zealand. There are also representative collections of Maori and Polynesian ethnology. The Otago university museum of natural history and ethnology is devoted mainly to the fauna of New Zealand and contains very fine specimens of Moa skeletons. The War Memorial museum at Auckland, the Geological Survey of New Zealand museum, and the Colonial museum at Wellington are also worthy of notice.

Africa.—The South African museums, Capetown, contain general and local natural history collections, also collections illustrating anthropology, ethnology and colonial art. The Durban museum is specially rich in mammals and contains a large amount

BY COURTESY OF THE FIELD MUSEUM OF NATURAL HISTORY, CHICAGO

HABITAT GROUPS OF CROCODILES AND WILD TURKEYS

Museum habitat groups are designed to show specimens in their natural surroundings. The effect of realism is produced by the use of painted backgrounds, wax-modelled foregrounds and skilfully arranged artificial lights. Both groups illustrated above are in the Field Museum of Natural History and were painted by Charles Abel Corwin

Group 1. Crocodiles (*Crocodilus acutus*). This species is found in Lake Ticamaya, Honduras, and averages about ten feet in length

Group 2. Wild turkeys (*Meleagris gallopavo silvestris*), still found in parts of the eastern United States

of anthropological material, one room is devoted to "Old Durban." The Rhodesian museum, Bulawayo, specializes in the zoology, geology and botany of Rhodesia. The Natal museum, Pietermaritzburg, contains an exceptionally fine series of specimens of African mammals mounted in their natural surroundings, and deals mainly with the natural history of South Africa.

There has been recently opened in Zanzibar a local museum. The Egyptological collections at Cairo are unsurpassed in the world. There is also a Geological Survey museum and Zoological gardens and museum at Giza.

Canada.—The National museum in Ottawa is an outgrowth of the Geological Survey. The National museum comprises the divisions of biology and anthropology, geology, palaeontology and mineralogy being maintained by the Geological Survey. The exhibits cover a wide range of Canadian ethnology, archaeology and natural history. The Ontario provincial museum, Toronto, the Natural History museum, Quebec, and the Vancouver museum are all making rapid progress.

THE CONTINENT OF EUROPE

France.—The most important museum in France is the *Muséum d'Histoire Naturelle,* in the *Jardin des Plantes,* Paris. The collections contain many types of specimens the result of the work of French naturalists. Others worthy of mention are the *Musée des Sciences Naturelles* at Lyons, and the *École Nationale Supérieure des Mines,* and the *Institut National Agronomique.*

Monaco.—The *Musée d'Océanographie* is perhaps the finest oceanographical museum in the world, while the *Musée d'Anthropologie Préhistorique* is also an important institution.

Portugal.—The Natural History museum in Lisbon is famous for its ornithological collection, while the museum of the Geological Survey in Lisbon represents the geology of the country.

Spain.—The museum of Natural Science at Barcelona is devoted entirely to biology, while the museum of Natural Science at Madrid contains collections both local and general of minerals, rocks and fossils.

Belgium.—The *Musée Royal d'Histoire Naturelle de Belgique* is specially noted for its palaeontological collections. The *Musée du Congo Belge* is devoted entirely to the natural history, political and social economy, economic products, means of transport and arts and sciences of that colony.

Holland.—In the Rijks Museum of geology, mineralogy and zoology at Leyden there are general and regional collections of considerable importance. The museum attached to the university in Amsterdam is specially rich in teaching collections.

Norway.—The Bergen museum is devoted almost entirely to Scandinavian natural history, and contains a specially fine collection of Silurian fossils from West Norway. The Municipal museum, Stavanger, deals with local zoology and general archaeology. The museum of Northern Antiquities at Oslo is restricted to the collections denoted by its title. The Norwegian People's museum at Oslo is a "folk" museum and is world famous. The Industrial museum at Trondjhem confines its attention to Norwegian industries and is also world famous. The aquarium at Trondjhem biological station, should also be noted, although, strictly speaking, it is not a museum.

Sweden.—The Royal Museum of Natural History at Stockholm is rich in palaeontological, botanical and archaeological material. The Nordiska museum is devoted to Scandinavian ethnology, while the recently built (1923) Natural History museum at Göteborg specializes in local geology, mineralogy, zoology and botany, and contains many type specimens.

Denmark.—The Museum attached to the University of Uppsala contains many great scientific treasures. The National museum at Copenhagen is the most important and is specially rich in Scandinavian and Danish antiquities. There is also a very fine Geological museum in this city with a wonderful collection of precious stones. The Natural History museum, Aarhus, founded in 1920, is devoted to geology, mineralogy and zoology. Several old castles throughout the country house wonderful collections of Danish antiques while there are numerous open air folk museums.

Italy.—There are museums in nearly all the large towns in Italy and attached to the universities. The *Museo Civico* at Genoa, the Geological museum at Bologna and the zoological collection at the aquarium at Naples are the most important.

Greece.—The Geological Survey museum at Athens, the mineralogical, the petrological and the zoological museums of the university at Athens have representative collections.

Switzerland.—The museums of Switzerland deal almost entirely with the natural sciences. The most important are (1) The Natural History museum, Berne, (2) The Natural History museum, Geneva, (3) The Zoology museum, Lausanne, and (4) The Natural History museum, Neuchâtel.

Germany.—In Berlin there are: (1) the *Museum für Naturkunde;* (2) the Ethnological museum; (3) the Anthropological museum; (4) the Mineralogical museum, and (5) the Agricultural museum. The first is rich in classical collections while the contents of the others are denoted by their names. In Hamburg there are a Natural History museum, an Ethnological museum, the Museum Godeffroy and the Museum Umlauff. The municipal museum of Bremen specializes in natural history and ethnology. Dresden contains a number of museums which embrace all the sciences and are extremely important to the specialist. In Leipzig there is an ethnological museum rich in Southern and Central European antiquities; while Munich has a Natural History museum, an Anatomical museum and an Ethnographical museum. The Natural History museum in Stuttgart is noted for its palaeontological collections. The museums at Hildesheim and Lübeck are worthy of special note as they are model provincial museums. The most recent museum in Germany is the *Deutsche Museum* in Munich opened in 1925; it contains a very valuable collection illustrating the history of technology and the exact sciences, physics, chemistry and astronomy and is comparable in some ways to the science museum in London, and the Gallery of Arts and Crafts in Paris.

Austria.—The Imperial Natural History museum in Vienna is one of the finest institutions of its kind in Europe. The mineralogical collection is unrivalled. The botanical and conchological collections are also world renowned. The Technological museum is mainly devoted to mechanical and technological science.

Hungary.—The ethnographical and anthropological collections at Budapest are extremely important. In the *Musée Social* the following departments are worthy of attention, human anatomy, industrial hygiene, prevention of accidents, contagious diseases and other health subjects.

Bulgaria.—The Natural History museum of the King of Bulgaria in Sofia is devoted to the geology, zoology and botany of Bulgaria. The National museum of Bulgaria deals with archaeology, architecture and the fine arts.

Rumania.—The Geological institute of Rumania contains a very fine collection of Rumanian minerals, rocks and fossils. The university laboratory of Rumania is rich in geological phenomena and general stratigraphy. The Natural History museum contains geology, zoology, comparative anatomy, oceanography, anthropology and ethnology. The collections of rare Rumanian fossils including *Dinotherium* and of Rumanian fauna are noteworthy. The museum of the Hermannstadt Natural History Society contains collections exclusively Transylvanian.

Czechoslovakia.—The National Museum of Prague is devoted almost entirely to natural history but there are also collections illustrating ethnology, archaeology and numismatics. The Technology museum of Czechoslovakia, also in Prague, deals with engineering, textiles, mining, chemistry, metallurgy and aeronautics.

Jugo-Slavia.—The Croat National museum contains departments of zoology, geology, palaeontology, archaeology, ethnology and the fine arts.

Poland.—The Industrial museum in Cracow is devoted specially to the arts and crafts. The Museum Dzieduszycki at Lemberg deals mainly with the fauna and flora of Poland and has also general collections of archaeology and ethnology. The museum at Posen is notable for its forestry exhibition. The Polish Museum

of Natural History at Warsaw comprises the collections of the University of Warsaw, the Branick collection, and the malacological collections of Prince Ladislas Lubomirski, brought together in 1919.

Russia (U.S.S.R.).—The Rumiantsov museum in Moscow is specially rich in natural history. The most important museum in Leningrad is the Imperial Academy of Sciences, illustrating the zoology, palaeontology and ethnology, not only of Russia but of foreign lands. There is a Mining Museum in Leningrad, also a museum of the Revolution.

EASTERN MUSEUMS

The American University museum, Beirut, contains zoological, historical and archaeological collections of Syria and Palestine; local Jurassic and Cretaceous fossils of Syria, also a herbarium of Syrian plants. The Constantinople museum is rich in Greek, Assyrian, Chaldean and Egyptian antiquities.

At the Imperial University at Tokio there is a wonderfully equipped museum devoted to the sciences, but more especially zoology. The Museum of Zi-Ka-Wei near Shanghai is confined almost exclusively to the zoology and botany of the valley of the Yang-tse-Kiang. Notable collections are (1) the birds of China, and (2) the mammals of the Far East. This collection contains many type specimens including Cervidae and Suidae.

CENTRAL AND SOUTH AMERICA

The National Mexican Museum of Natural History contains general mineralogical, geological, zoological and botanical collections combined with the Zoological and Botanical Gardens.

The National Museum, Santiago, Chile, is devoted almost entirely to natural history and there is also a department of anthropology. The herbarium contains a type collection of Chilean plants. There is also a Natural History museum at Valparaiso.

The *Museo d'Estado de Bahia,* Brazil, is especially rich in precious stones and fossils, but there are also zoological and botanical collections from the State of Bahia. The National Museum of Natural History is as its name indicates devoted specially to that subject and the local collections are a special feature. There are, however, departments of ethnology and archaeology dealing mainly with the Indians of Brazil, Bahia, and Peru. At Para there is the Museo Paraense or the Museo Goldi. At Sucre, Bolivia, there is a Natural History and Anatomy Museum.

Colombia has the Institute Museum at Bogotá, containing notable collections of quaternary mammals from the Bolivian Savannah, also birds, mammals and lepidoptera from Bolivia.

There is a Natural History museum at San Jose, Costa Rica; and at Montevideo, Uruguay, the Natural History museum contains general geological, zoological and botanical collections, including a herbarium of the flora of Uruguay; there are also departments of archaeology and ethnology.

At Buenos Aires, there is a very progressive institute, the Argentine National Museum of Natural History, while at Cordoba there are two University museums: the Museum of Botany and Zoology, and the Museum of Mineralogy and Geology.

See E. Howarth and H. M. Platnauer, *Directory of Museums of Great Britain and Ireland,* etc. (1911); H. Miers, *Report on the Public Museums of the British Isles* (to the Carnegie United Kingdom Trustees, 1928). (J. J. Sı.)

THE UNITED STATES

Museums of science in the United States are varied in their origin, establishment, purposes and administration; they may be related to the educational or scientific work of some society or college, or to that of a city or State, or, even, as in the case of the United States National Museum, to that of a nation. They may be said to date from the founding of the Charleston museum in 1773 by the Charlestown (*sic*) Library Society. In 1815 it was transferred to the Literary and Philosophical Society of South Carolina, in 1828 to the Medical college, and in 1850 to the College of Charleston; finally (1907) it was embodied in the present Public museum.

The Museum of the Academy of Natural Sciences of Philadelphia, was founded in 1812 in connection with the organization of the society. This was for many years the most important scientific society, so far as natural history was concerned, in the United States, and it still remains in the front rank. It contains much material, including many types, in zoology and palaeontology, studied and described by earlier American naturalists; the collection of molluscs is the finest in the United States.

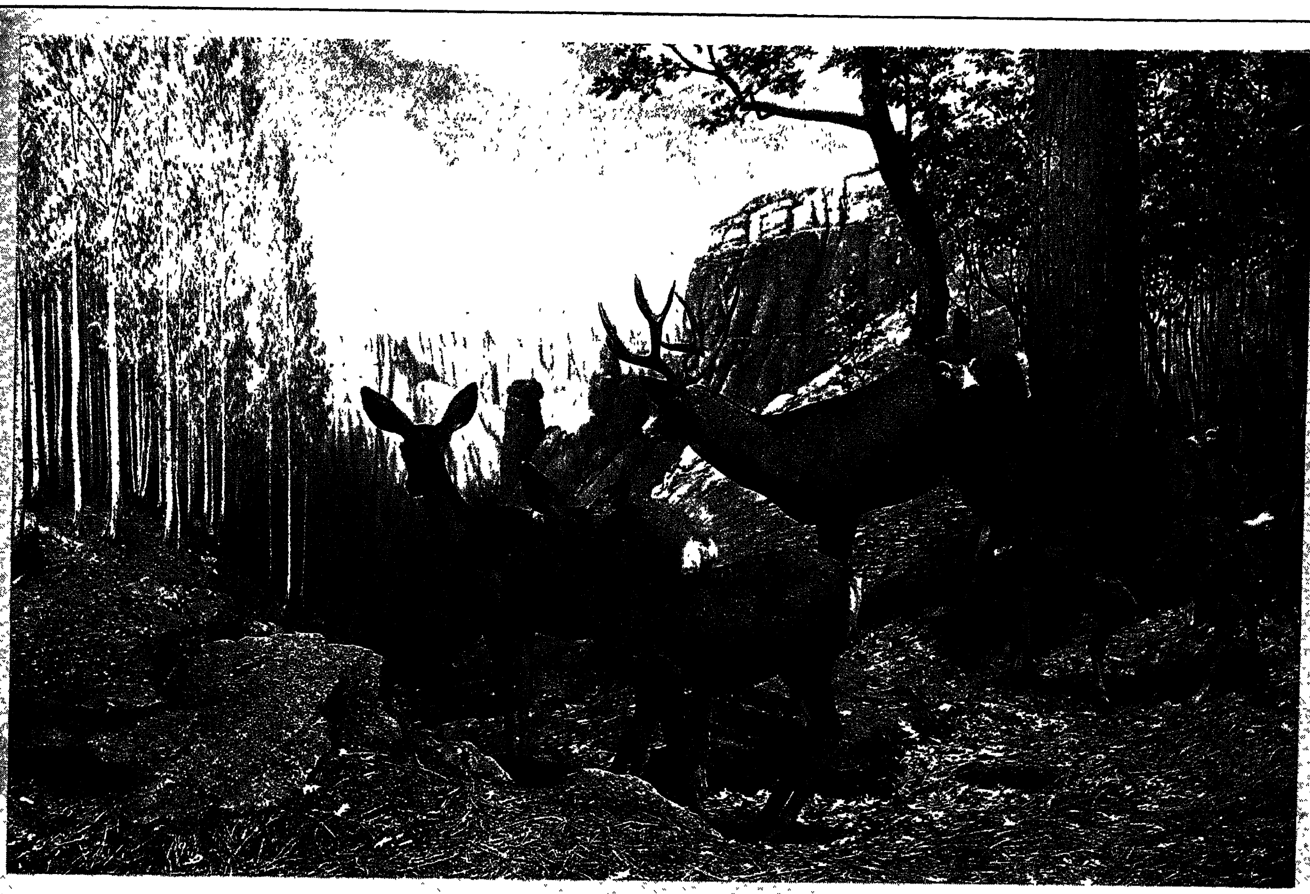
The Boston Society of Natural History was founded in 1830 as an outgrowth of the Linnean Society of New England. Originally, so far as exhibits were concerned, a museum of general zoology, its scope has been restricted to New England. The study collections are large, and include many types and figured specimens in various branches of natural history. The Museum of Comparative Zoology, a part of Harvard University, at Cambridge, Mass., had its origin in the collections purchased from Louis Agassiz for $12,000 in 1852. It was incorporated in 1859 and, later, received most important support from Alexander Agassiz. It was one of the first, possibly the first, of American museums not founded and controlled by a scientific society. Originally mainly a museum of research, its exhibits were arranged to relate to courses of study in the university; recently they have been rearranged to interest and instruct the public. The reserve, or study collections, are large and varied; they are especially rich in birds, reptiles and fishes.

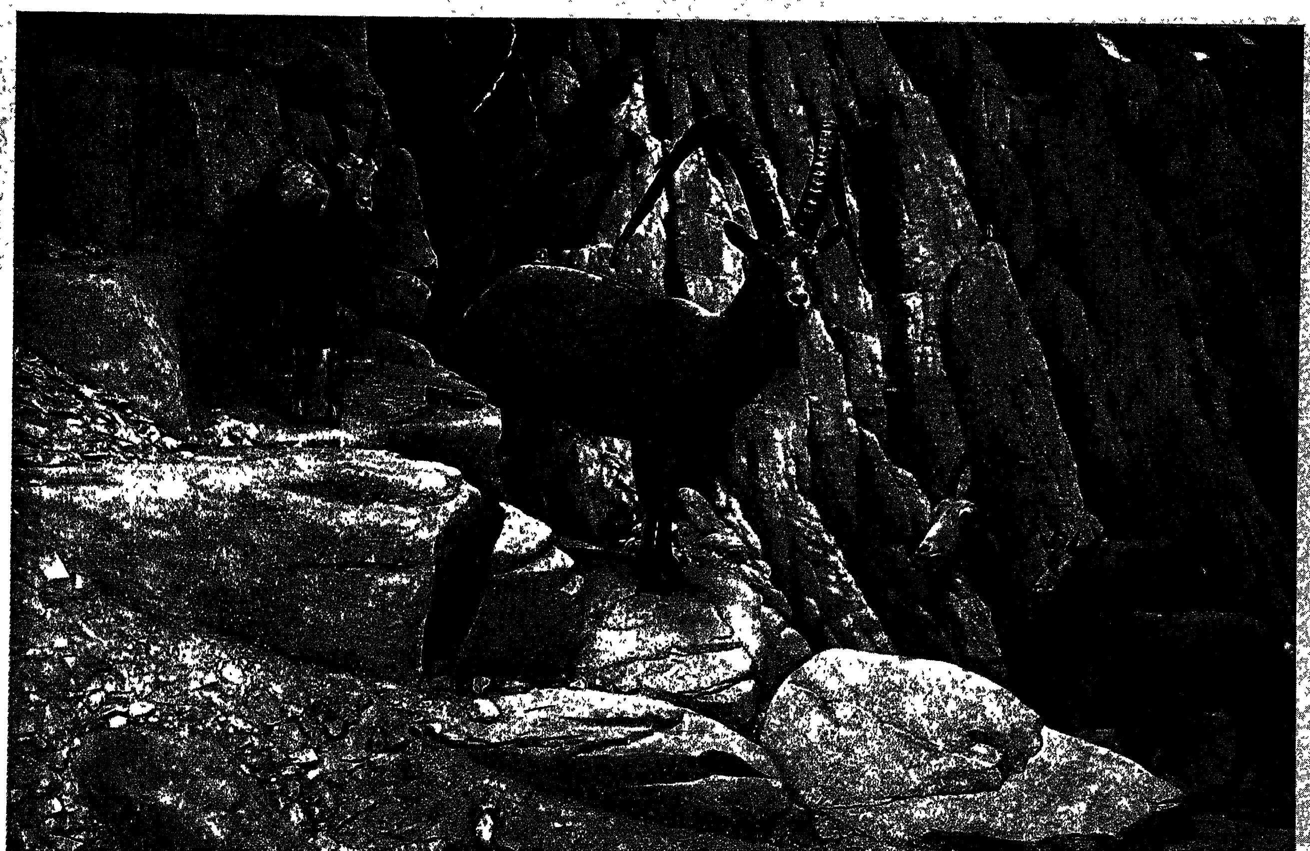
The founding of the American Museum of Natural History, New York, the largest of American museums, in 1869, marked an important step, in that it definitely recognized the interest of the public in museums by providing for the housing and care of the building by the city, while the scientific work of the institution was to be carried on from private funds. This principle of "community of interest" has been widely adopted. It includes all branches of natural history (save botany) and anthropology. There are more complete skeletons of extinct animals, particularly dinosaurs, on exhibition than in any other institution in the world, and the series of reproductions of invertebrates in glass is unique.

The history of the United States National Museum, Washington, D.C., given by Dr. Goode in detail, in the *Report* of the United States National Museum for 1891, is involved. The germs of this institution may be ascribed to the collection of minerals included in the Smithson bequest (1826), and in the National Institution (long defunct) for the Promotion of Science (1840). The term National Museum was first used by Prof. Henry in 1847, but was not legally applied to the Government collections until 1876. Wilkes's exploring expedition gave a great stimulus to the United States National Museum, but the exposition of 1876 was the final cause for its establishment. The collections include, besides natural history in its various branches, anthropology, history, technology and even art. The minerals and molluscs rank with the first. In technology, the material illustrating the development of the telephone, telegraph and electric light is unique.

The acquisition and preservation of material for study was, at first, the main purpose of museums of science, exhibition being a secondary consideration. The gathering of material was largely passive. Museums took such specimens as were brought to them, but as they grew in importance expeditions were sent out for the express purpose of securing material. Among the leaders (aside from the Government exploring expeditions) were the Peabody Museum of Yale University, under Prof. Marsh, and Princeton University, under the direction of Prof. Scott. This has now become an important and essential branch of museum work. That museums of science might be a source of "rational amusement" was recognized by John Edward Gray in his appeal for a new building for the natural history collections of the British Museum; their educational possibilities came later, and were largely due to Sir William Flower, when director of the British Museum. Dr. G. Brown Goode, in charge of the United States National Museum, under Prof. Baird, was an admirer of Flower, and a great believer in the educational value of museums, especially of their exhibition collections, and to him America owes, to a great extent, the "popularizing" of museums of science.

Once fairly started, the movement to make museums educa-





BY COURTESY OF THE FIELD MUSEUM OF NATURAL HISTORY, CHICAGO

HABITAT GROUPS PAINTED BY CHARLES ABEL CORWIN AND ARRANGED BY C. J. ALBRECHT

1. Group of mule deer (*Odocoileus hemionus*) in the Field Museum, Chicago. The species is found in the western United States

2. Group of Asiatic ibex (*Capra sibirica*) in the Field Museum, Chicago. They range in Asia from the Altai to the Himalaya Mountains

tional rapidly gathered weight, until it has become recognized as one of their important objects, and special attention is given to the arrangement and labelling of exhibits and to affiliation with schools. (*See* section on *Visual Education in Museums.*) The most recent instance of the change in policy of a museum of science is the rearranging of the collections of the Museum of Comparative Zoology at Harvard along educational lines, though the first step may be said to have been taken some years ago by the introduction of the Blaschke glass flowers.

There are, great and small, about 325 museums of natural history in the United States, but it is uncertain just how many of these are entitled to be called museums of science. The history of a few of the more important has already been noted; the location of other leading museums, and the more noteworthy of their collections, are as follows:—

The Field Museum of Natural History (originally Field Columbian museum), Chicago, was founded by the gift of collections by Marshall Field at the close of the Columbian Exposition of 1893. It has important collections in natural history and ethnology, being particularly rich in birds of North and South America, and mammals of those continents and Africa. The collection of meteorites is the largest in the world; the exhibits in botany lead all others in the United States. A special gift from N. W. Harris provides for unusually fine circulating exhibits for schools.

The New York State Museum, Albany, was organized as the State Cabinet of Natural History, the original collections being the material gathered in the course of the natural history survey of the State between 1836 and 1843. In 1873 it was established as the State museum, and in 1889 made a part of the University of the State of New York. It is supported entirely by the State, is the largest of the State museums, and its publications the most important. It contains many types and figured specimens of the past and present flora and fauna of the State, and its historical collections are extensive. Other important State museums are those of Pennsylvania (Harrisburg), Illinois (Springfield), New Jersey (Trenton), Indiana (Indianapolis), Georgia (Atlanta) and Florida (Gainesville).

The Public Museum of the City of Milwaukee had its origin, in 1882, in the gift of the collections of the Wisconsin Natural History Society. Its collections include both natural history and history, and special attention is given to work with the schools and to exhibition.

The Carnegie Museum, Pittsburgh, Pa., has important collections of fossil vertebrates, South American birds and *Lepidoptera,* a speciality being African butterflies.

The Colorado Museum of Natural History, Denver, founded in 1902, is supported largely by the city; its scope includes, primarily, the natural history of the State, and also art and industry. It has given much attention to fossil vertebrates.

The Buffalo Society of Natural Sciences, Buffalo, N.Y., organized in 1861, was almost the first museum in which the exhibits were definitely planned and arranged on an educational basis. It is particularly strong in fossil invertebrates from the Devonian near Buffalo.

The California Academy of Sciences, San Francisco, organized in 1853, gives particular attention to the fauna and flora of the Pacific coast and western States, and while the collections were largely destroyed by the fire of 1906, they have again been brought to a high level. It is particularly rich in reptiles, and the series of giant tortoises from the Galapagos islands is unique.

The Peabody Museum of Yale University, New Haven, dates from 1866; it is rich in fossil vertebrates, especially dinosaurs, and possesses the first birds with teeth to be discovered, and important examples of early horses. Its exhibits are arranged with special reference to their educational influence and work with public schools.

The University of Michigan museum, Ann Arbor, Mich., one of the largest and most active of museums connected with colleges, is strong in ethnology, particularly of the East, and in collections representing the resources of the State. A special feature is its work in experimental biology and the problems of conserving natural resources. (F. A. Lu.)

Visual Education in Museums.—In the United States, museums are being utilized to an unprecedented degree for visual education in the public schools and colleges. Scores of museums have arisen in all parts of the country, but their use as a part of the educational system is best exemplified in the larger cities. The American Museum of Natural History in the City of New York may be selected as typifying this movement because of the extent to which it has been developed in connection with the immense school population in that city. The American museum deals with upwards of 1,000,000 school children within the five boroughs of New York. During the year 1927, it made more than 9,900,000 contacts with this clientele by means of lectures in museum class-rooms devoted to the purpose, exhibition hall talks; classes for children with defective eyesight, and by more formal lectures, illustrated by lantern slides and motion pictures dealing with natural history, geography, exploration and kindred topics. Series of nature study collections in cabinets are circulated through the public schools and placed on loan in public libraries throughout the city. Sets of coloured lantern slides are arranged, based on the museum exhibits and explorations, and on various topics suggested by public school teachers. An outdoor museum and a series of nature trails have been established in the Adirondack State park, under the museum's auspices, that school children and others may study animal and plant life in their natural surroundings. In this way 576 schools within the city limits were served during the year 1927.

Within the museum halls themselves, mammals, birds, reptiles, amphibia and fishes are mounted or modelled in lifelike attitudes, grouped as in nature and shown in a setting consisting of a pictorial painted background, reproducing faithfully the natural environment, with trees, shrubbery and other accessories modelled to close similitude with nature. A similar method is followed with the lower forms of life, such as the marine and fresh-water invertebrates. In life, many of these creatures are soft-bodied and often translucent organisms of most beautiful and delicate coloration. In the American Museum of Natural History, they are modelled in glass, wax and other materials, tinted with the colours of the living animal, and often represented in groups having translucent painted backgrounds through which light filters, so as to give the illusion of an undersea environment.

The modern museum spares no pains to secure accuracy as well as beauty in these pictorial exhibits or groups. The work begins with the outfitting of expeditions to study the living creatures in their actual environment. Skilled artists accompany the field parties to make detailed studies of the animals desired. Photographs and moving pictures are secured, and careful notes are made, both of the animals themselves and of the associated animal and plant life, as well as the inanimate features of the environment. Actual specimens are brought back for detailed, scientific study, and even trees, bushes and rock specimens are transported to the museum, when terrestrial groups are concerned. The museum gathers its facts from nature by first-hand exploration. The data are analyzed technically, from a scientific standpoint, to evaluate the new knowledge thus obtained, and finally, by means of lifelike exhibits and the popular explanatory labels and handbooks describing them the results are interpreted to the public at large, as a matter of liberal education.

(R. W. M.)

Museum Habitat Groups.—A term applied to the exhibition in museums of certain forms of natural history specimens in their native habitat or environment, so as to render the display both attractive and informing. This form of exhibit has been mainly developed in America and is the direct outcome of the modern tendency to make museums more effective in popular scientific education. These groups have been principally utilized in zoology and anthropology, but they are also applicable to botany and geology.

Some suggestion of local environment for mounted specimens, usually confined to a simple support or base, has been practised from time immemorial, but the careful rendering of natural conditions, including painted backgrounds, rich and elaborate, or simple, as the subject may require, is a recent development, and

was given special impetus through the initiative and original methods of the late Carl E. Akeley.

In the preparation and installation of this type of exhibition, the possibilities of which are large, peculiar difficulties and limitations arise; each new undertaking presents some new problem of its own, the solution of which may require an unusual degree of adaptiveness and resourcefulness.

General Treatment.—An illusion of nature is the first and basic idea, which calls for a naturalistic treatment of background, even realistic where painting merges into the realism of the foreground. The complex nature of these productions has usually been best attained by the collaboration of two or more artists, sculptor and painter with trained artisan assistants, working with mutual understanding and enthusiasm and an acquaintance as intimate as possible with the particular matter in hand.

The more common forms of installation may be classified in progressive steps as follows: (1) in the open hall; (2) in cases glazed on all sides; (3) with background painted on one side, glass on three; (4) background on two adjacent sides, glass on the other two, presenting two aspects; (5) one glazed side or opening, with curved background, enclosing all sides of the group except the front, thus admitting of a complete illusion, as if one were looking out into the open from a window; (6) the logical last step is the continuous or cycloramic background, viewed from a central vantage point. This form has been successfully applied to certain gregarious groupings. (*See* MUSEUM: *Visual Education.*) (C. A. Co.)

MUSH, a kaza in the Bitlis vilayet of Asiatic Turkey. It is situated at the mouth of a gorge in the mountains on the south side of the plain, the surrounding hills being covered with vineyards and some oak scrub. The castle, of which there are some remains, is said to have been built by Mushig, an Armenian king of the province Daron, who founded the town. Good roads lead to Erzerum and Bitlis. There are 21,414 inhabitants. The winter climate is cold, with a heavy snow fall. Some miles to the west at the edge of the plain is the celebrated monastery of Surp Garabed or St. John the Baptist, an important place of Armenian pilgrimage.

Mush plain, 35 m. long by 12 broad, is very fertile, growing wheat and tobacco. The Murad or eastern Euphrates traverses the western end of the plain and disappears into a narrow mountain gorge there. Wood is scarce and the usual fuel is *tezek* or dried cow-dung. There are several sulphur springs, and earthquakes are frequent and sometimes severe.

MUSHET STEEL, a high carbon manganese-tungsten steel developed about 1868 by the Englishman Robert F. Mushet. Whereas steels known before that time required rapid quenching from a high heat in order to become hard, Mushet's steel was excessively hard after air cooling and retained that hardness even after high tempering. For these reasons it was called "air-hardening" or "self-hardening" steel, and was used for machine tools for cutting the harder steels and cast irons. Owing to the lack of uniform ferro-alloys needed in the manufacture, these early high-alloy steels varied in chemical composition between the following approximate figures: carbon 1·85 to 2·15; manganese 2·5 to 1·5; tungsten 9·0 to 5·5.

Other air-hardening tool steels introduced to compete with Mushet steel without infringement on the patent rights were lower in carbon, contained a few per cent of chromium or substituted molybdenum for the tungsten. Present day representatives of this class of tool steel are the "fast-finishing" steels, an inexpensive quality for cutting hard metal. A typical analysis contains 1·25% carbon, 0·30 manganese, 3·5 tungsten and 0·3 chromium. (E. E. T.)
